INDEX OF CONTENTS.

JULY TO DECEMBER, 1905.

(FOR SPECIAL HEADINGS SEE UNDER BOOKS; CERTIFICATES; LAW NOTES; NURSERY NOTES; OBITUARY; PLANT PORTRAITS; PLANTS NEW; SCIENTIFIC COMMITTEE; SOCIETIES; AND ILLUSTRATIONS.)

A

ACETYLENE light, use of, in forcing plants, 31
Adiantum cuneatum, culture of, 374
 Afforestation and the labour question 313
Agapanthus caulescens, 459; *A. umbellatus globosus*, 237, 459
 Agave, the genus, 161
 Agaves, some garden varieties of, 346
 Agricultural College, Wye, 70, 313
 Agricultural returns, 216
 Agricultural (Royal) Society's exhibition, 63
 Agriculture at Cambridge, 392
 Agriculture, the Board of, 415, 441
Ailanthus Vilmoriana, 276
 Aldenham House gardens, 64
Aleyrodes vaporariorum, a pest of Ferns, 48
 Allamandas at Kew, 107
 Alpine garden, the, 125, 223
 Alpines at Nithbank House, Dumfries, 125
Ananias phalloides, poisoning by, 175
Amelanchier canadensis in autumn, 352
 American florists, a society of, 201
 American Universities, grants to, 361
 America, nursery imports of, 415
 Ampelopsis, a new, 265, 309
Ancistrocheilus Thomsonianus var. *Gentili*, 324
Anemone blanda and its allies, 339
 Annuals, what are? 186, 204, 251, 268
 Ants in glasshouses, 20
 Apiary, the, 9, 69, 109, 149, 183, 250
 Apple, a large, 345; Lord Suffield, hardness of, when in flower, 457
 Apples: Coronation, 200; Five Crown Pippin, 154; Warner's King, 429, 444; Yellow Ingestre, 260
 Apple-trees, chemical manure for, 416; espalier trained, 97
 Apples, bruised, 281; from British Columbia, 125; marketed in shallow boxes, 331
 Apricots St. Ambroise and Powell's Late, 203
 Arbor Day at Eynsford, 361, 378
Argemone grandiflora, 127
Arundinaria Simoni, the flowering of, 380
Aspidia buphthalmiflora, 404
Asplenium septentrionale in North Wales, 371, 396
Aster sub-ceruleus, 23, 52
 Asters, some neglected, 6
Astilbe grandis, 426
 Aucuba, grafting the, 229, 268
 Awebury, Lord (*The Life History of British Flowering Plants*), 409, 436
 Azalea beds, suitable plants for, 432, 443, 456
 Azaleas, "Carmichael," 268
 Azara microphylla, fruit of, 71

B

BAMBOOS, the flowering of, 200, 229, 362; in California, 338

Bananas and mealy bug, 297, 362
 Bananas from Jamaica, Barbados, and Canary Islands, compared, 178
 Battersea Park, 152; Chrysanthemums in, 330
 Beans, preserving runner, 204; low prices for, 204
 Bee Exhibition at the Crystal Palace, 200
 Belgian Forestry, 181, 182, 307, 426
 Belsize Court, Hampstead, 389
 Belvedere, Isle of Wight, the gardens at, 41
 Benevolent Institution, Gardeners' Royal, 200, 280, 393
 Bequest to horticulture, 170
Berberidopsis corallina flowering in Lydhuist gardens, 166
 Berger, Alwin (*Florula mortolensis*), 59
 Bermuda Lily culture, the, 44
 Btreshanger House, Kent, 171
 Birmingham, a suburban garden in, 233
 Betting, evil resulting from, 426
 Blackberry Lucretia, 71
Blakea gracilis flowering at Kew, 229
 Board of Agriculture, the, 415, 441
 Books, gardening, a classified catalogue of, 377; sale of, 345, 393, 405

BOOKS, NOTICES OF:—A Book about Salads (*Alfred Broadbent*), 131; Alpine Flora (*Drs. Hegi and Dunzinger*), 70; Amateur Gardening, 409; Beautiful Bulbous plants (*John Weathers*), 294; British Moss-flora (*Dr. Braithwaite*), 111; British Trees (*R. V. Cole*), 150; Botanical Magazine, 50, 92, 151, 200, 264, 344, 409; Bulletin de la Société Française d'Horticulture de Londres, 310; Carnations, Picotees, and the Wild Garden Pinks (*E. T. Cook*), 212; Carnations, Picotees, and Pinks (*H. W. Weguelin*), 70; Choice Ferns for Amateurs (*George Schneider*), 7; Critical Revision of the Genus *Eucalyptus* (*J. H. Maiden*), 425; Dictionnaire Iconographique des Orchidées, 324; Economie forestière (*Huffel*), 337; English Idioms and Colloquialisms (*Arthur Burvenich*), 437; Experiments with Plants (*W. J. Osterhout*), 26; Faraday House Journal, 92; Far Eastern Maples (*James H. Veitch*), 161; Flora and Sylva, 151; Flora Brasiliensis, 124; Flora Capensis, 6, 170; of Tropical Africa, 425; Flore de France (*Abbé Coste*), 151; Florula Mortolensis (*Alwin Berger*), 59; Fruit Preserving (*J. H. Cook*), 12; Fungus Flora of Yorkshire (*Marsce and Crossland*), 309; Future Forest Trees (*A. Harold Unwin*), 404; Garden Album and Review, 441; Gerarde's Herbal, 130; Glossary of Botanic Terms (*B. D. Jackson*), 403; Greenhouses, how to make and manage them (*W. F. Rowles*), 26; Guide-Books received, 13; Handbook of Forest Botany (*H. Marshall Ward*), 198; Handbuch der Pflanzenkrankheiten (*Prof. Dr. Paul*

Sorauer), 46; Horticultural Directory, 111; How to know Wild Fruits (*Maud Gridley Peterson*), 26; How to make and manage a Garden (*W. F. Rowles*), 26; Index Filicum, 441; Insect Life (*F. V. Theobald*), 26; Insects and Fungi injurious to Plants (*G. F. Strawberry*), 226; Journal of Economic Biology, 31; Journal of Economic Botany, 12; La Vie à la campagne, 151; L'Hybridation des Plantes (*M. Raphael de Noter*), 26; Life History of British Flowering Plants (*Lord Avebury*), 409, 436; Poultry Farming, 326; Publications received, 13, 32, 48, 92, 112, 129, 160, 186, 201, 260, 281, 313, 437; Monographie Horticole des Plantes Bulbeuses (*M. Raphael de Noter*), 27; Monograph of the Genus Primulaceæ (*Pax and Knuth*), 393; My Garden in the City of Gardens, 27; Rules for Judging, 361, 426; Sowerby's English Botany, 361; Stone Gardens (*Rose Haig Thomas*), 310; Summer Holidays (*Percy Lindley*), 12; The Amateur Gardener's Rose-Book (*Dr. Julius Hoffman*), 26; The Art of Conserving (*Vere Galway*), 92; The Book of Garden Design (*Charles Thonger*), 275; The Book of the Scented Garden (*F. W. Burbidge*), 51; The Chrysanthemum (*Arthur Herrington*), 394; The Estate Nursery (*J. Simpson*), 151; The Four Gardens (*Ilindasyde*), 326; The Garden that I Love (*Alfred Austin*), 403; The Uses of British Plants (*Prof. Henslow*), 280; The Vegetable Garden (*Henry de Vilmorin and W. Robinson*), 70; Varieties of Fruits, 426; Who's Who, 441; Who's Who Year Book, 441; The Italian Lakes, *Richard Bagot*, 451
 Books, sale of gardening, 345, 393, 405
 Botanical Congress at Vienna, a, 10
 Botanists, old-time Flemish, 249
 Botany, experimental, 170
Brachystelma Barberæ flowering at Kew, 132
 Bracken Fern, a crested form of the, 188
 Braithwaite, Dr. (*The British Moss-flora*), 111
 Bramble Lucretia, 32
 British Columbia, apples from, 425; fruit growing in, 151
 British Science Guild, the, 313, 328
 Bruges, horticultural exhibition at, 117
 Brussels Botanic Garden, 50, 232
 Brussels International Horticultural Congress for 1910, 361.
 Brussels, horticultural meetings at, 110, 333
 Budding fruit trees, 144
Bulbophyllum Lobbii colosseum, 184
 Burbank, Luther, banquet in honour of, 293
 Burbidge, F. W. (*The Book of the Scented Garden*), 51
 Burnham Beeches, 141; the pollarding of, 186
 Burnham, remains of monastic buildings at, 175

Burvenich, Arthur (*English Idioms and Colloquialisms*), 437

C

CABBAGES, transplanting, 252
 Cactus, "scab" disease in, 125
Callipsyche kewensis ×, 372
Calodendron capense, 52
Calycopteris floribunda, a water-yielding plant, 170
 Cambridge, Agriculture at, 392
 Cambridge, Forestry at, 312; Botanic Gardens, 46, 434
Campanula Michauxioides, 130; *C. punctata*, 169; *C. turbinata* Isabel, 72, 96; *C. Zoysii*, 228; Campanulas of the carpatica group, 145
 Canning fruits, 126
 Caoutchouc, a new source of, 441
 Cape of Good Hope, note from the, 170
 Cape Town, abnormal rainfall at, 105
 Carberry Tower, Midlothian, 194
 Carbonate of baryta, a poison for rats, 32
 Cardiff, the Roath Park at, 31
 "Carmichael" Azaleas, 268
 Carnations: Bob Acres, 72; Miss Willmott, 72
 Carnations, 61; staging, at flower shows, 71, 96, 154; a winter exhibition of, 380, 410, 443, 457; at Tring Park, 33; some desirable varieties of, 71; winter-flowering varieties of, 331, 362, 429, 443; origin of the name of, 449
 Carpet-bedding at Maidenhead, 12
 Carrots, storing, 272
Carya tomentosa, 276
Castanospermum australe, 244; in California, 338; seeds of, 441
 Cattle Show, the Smithfield, 408
Cattleya amethystoglossa, 105; *C. Harrisoniæ*, culture of, 267; *C. Mossiæ* "Gloire de la France," 123; *C. Skinneri*, 325
Cereus, a revision of the genus, 232

CERTIFICATED FRUITS AND VEGETABLES.—Apples: James Kirk, 412, 447; Star of Devon, 382; Cauliflower Walcheren, 284; Kale Drumhead, 382; Melon Conference, 284; Peas: Essex Wonder, 34; The Bell, 158; The Scotsman, 158; Peach Violette Hâtive, 158; Plum September Prolific, 218; Potatoes: British Hero, 382; British Queen, 158; Cigarette, 382; Dalhousie Seedling, 317; Denbigh Giant, 382; Duchess of Cornwall, 317; Epiare, 158; Forbe's Sensation, 317; Harbinger, 158; Hurst's Favourite, 382; Ideal, 158; May Queen, 158; Peacemaker, 412; Rouge Royal, 158; Southern Star, 382; The Gardener, 317; Strawberry Bedford Champion, 34; Tomatos: Carter's Sunrise, 34; Fillbasket, 158; Holme's Supreme, 158; New Dwarf Red, 158; Norfolk Hero, 158; Satisfaction, 158; Princess of Wales, 158; Yellow Cherry, 108

- CERTIFICATED PLANTS.**—*Adiantum Mayii*, 74; *Antigonon leptopus*, 316; *Astilbe grandis*, 74; *Begonia Mrs. Arthur Paget*, 55; *Begonia Water-Lily*, 55; *Berberis vulgaris macrophylla foliis purpureis*, 115; *Betonica spicata robusta*, 55; *Brassavola cucullata*, 218; *Buddleia variabilis magnifica*, 115, 157; *Bulbophyllum Lobbi colosseum*, 53; *Caladium Colonel John Hay*, 55; *Calanthe japonica*, 218; *Campanula White Star*, 115; *Canna nigra*, 190; *Carnations: Aurora*, 446; *Bob Acres*, 34; *Countess of Radnor*, 34; *Fair Maid*, 446; *Liberty*, 74; *Miss Willmott*, 55; *Pride of Westbury*, 34; *Roy Morris*, 115; *The Cardinal*, 316; *Viscountess Ebrington*, 74; *Victory*, 316; *Xmas Eve*, 381; *Cattleya* × *Germania magnifica*, 115; *C. × Iris "His Majesty"*, 254; *C. × Iris inversa*, 218; *C. × Iris magnifica*, 218; *C. × Kienastiana*, *Oakwood variety*, 218; *C. labiata Hercules*, 348; *C. × Lord Rothschild*, var. *Fairy Queen*, 316; *C. × Marie Henriette de Wavrin*, 316; *C. × Maroni Westfield variety*, 254; *C. Mossæ alba*, *Tracy's variety*, 53; *C. M. Reineckiana excelsa*, 53; *C. × Mr. Pitt var. magnifica*, 382; *C. × Petersii var. Mrs. Francis Wellesley*, 348; *C. Warscewiczii "Our Queen"*, 53; *Centaurea (strain)*, 115; *Chrysanthemums: Algeon Davis*, 334; *Beatrice May*, 335; *British Empire*, 398; *Dora Godfrey*, 335; *Dr. Enguehard*, 446; *E. J. Brookes*, 335; *F. G. Oliver*, 335; *Frank Greenfield*, 335; *Geo. Bowness*, 217; *Goacher's Pink*, 271; *Godfrey's Eclipse*, 334; *Harrie*, 217, 271; *J. G. Shrimpton*, 334; *John Peed*, 398; *Kate Palgrave*, 398; *La Vestale*, 233; *Mad. Marguerite de Mons*, 335; *Mad. R. Oberthur*, 398; *Mary Richardson*, 347; *Maud Matthews*, 398; *Maxim*, 271; *Miss Codrington*, 335; *Miss Irene Cragg*, 347, 398; *Miss Miriam Hankey*, 415; *Money-maker*, 271; *Mrs. A. T. Miller*, 316; *Mrs. D. Willis James*, 335; *Mrs. Frank Penn*, 316, 335; *Mrs. George Beech*, 415; *Mrs. R. Hooper Pearson*, 316, 335; *Mrs. Swinburne*, 415; *Mrs. Walter Jinks*, 334; *Mrs. W. Knot*, 335; *Norman Davis*, 316, 335; *Perle Chatillonnaise*, 271; *Phyllis*, 398; *Prickett's Octobre*, 334; *Reginald Vallis*, 334; *Reine des Roses*, 347; *Rimmel*, 316; *Souvenir de Lombraz*, 398; *Terra-cotta Soleil d'Octobre*, 316, 335; *Triomphe de Montburn*, 411; *Warrior*, 335; *Well's Masseur*, 217; *Codiaeum Edmontonense*, 55; *Cynochetes peruvianum*, 218; *Cymbidium Huttoni*, 34; *Cymbidium × Maggie Fowler*, 316; *Cypripedium × Actæus Chardwarensis*, 382; *C. A. F. H. Cann*, 411; *C. Daisy Barclay*, 34; *C. × G. C. Whitelegge*, 316; *C. Godefroyæ citrinum*, 34; *C. Godefroyæ leucocheilum*, "Goodson's variety," 190; *C. insigne Aberdeen*, 447; *C. Lawrenceanum Hyeatum*, "Bank House variety," 34; *C. × Lord Ossulston*, 317; *C. purpuratum*, "Tracy's variety," 254; *C. × Sanderæ*, 348; *C. tessellatum rubens*, 447; *C. × Thalia giganteum*, 382; *C. × Thalia Mrs. Francis Wellesley*, 446; *C. × The Baron*, 382; *C. × triumphans*, 348; *C. × villosa-Rothschildianum*, 218; *C. × Mary Lee Drewett's variety*, 447; *Cyrtanthus sanguineus glaucophyllus*, 253; *Dahlias: Alight*, 253; *Blush Gem*, 190; *Cynthia*, 253; *Daisy*, 217; *Daisy Easton*, 190; *Delicacy*, 253; *Edward Drury*, 220; *Faunus*, 253; *Favourite*, 253; *H. Shoemith*, 217, 220; *D. Iris*, 220; *Ivanhoe*, 253; *Kitty Barrett*, 220, 253; *Little Fred*, 253; *Mariner*, 220; *Matador*, 220; *Mrs. G. Stevenson*, 253; *Mrs. H. Shoemith*, 217; *Lady Fair*, 220; *Midget*, 220; *Mrs. F. Grinstead*, 220; *Mrs. F. H. Cook*, 217; *Mrs. MacMillan*, 217, 253; *Nelson*, 190, 220; *Peacemaker*, 253; *Peach*, 217; *Pink Perfection*, 220; *Primrose*, 217, 253; *Starlight*, 217; *Stromboli*, 190, 253; *T. A. Havemeyer*, 157; *The Pilot*, 217, 220; *Thora*, 217, 220; *Titus*, 253; *Tom-tit*, 217, 253; *Veronique*, 253; *Victorian*, 253; *White Lady*, 220; *William Marshall*, 157, 220; *Delphinium Snowflake*, 34; *Dendrobium ciliatum annamense*, 115; *D. Phalanopsis*, Miss *Louisa Deane*, 317; *D. Thundersleyense*, 348; *D. striatum*, 382; *Diervilla (Weigela) rosea var. Saturne*, 217; *Disa pulchra*, 382; *D. p.*, *Tring Park variety*, 382; *Epidendrum tricolor*, 317; *Erica cinerea "Skelwith Fold variety"*, 34; *Eschscholtzia Carmine King*, 34; *Gladolus: French Fleet*, 157; *Peace Envoy*, 157; *Lady Inchiquin*, 115; *Godetia Schamini fl. pl.*, 190; *Grohya galeata*, 115; *Heimerocallis Dr. Regel*, 115; *H. × luteola*, 34; *Ixora Mars*, 190; *Lælia-Cattleya × Berthe Fournier Westonbirt variety*, 157; *L.-C. × Chardwarensis*, 74; *L.-C. × Clive Appleton's variety*, 317; *L.-C. × Clive Westonbirt variety*, 446; *L.-C. × crispohardyana*, 251; *L.-C. × Epicasta*, *Gatton Park variety*, 411; *L.-C. Issy var. cuprea*, 190; *L.-C. × luminosa Rosita*, 254; *L.-C. × Massangeana Harry Goodson*, 34; *Lilium leucanthum*, 190; *L. sutchuenense*, 74; *Lobelia Kathleen Mallard*, 190; *Masdevallia cucullata*, 317; *Maxillaria picta Warley variety*, 74; *Miltonia Cogniauxia*, 190; *M. FERN - NAMES.

THE question of the proper naming of new varieties of Ferns is one of such importance that some consideration should be given to the principles which should underlie it. Unfortunately, in this particular direction, as with the naming of plants generally, we are handicapped in our endeavour to secure a consistent and correct system of naming by the fact that we have inherited an immense number of names which, to say the least of it, were never given on enlightened lines. A large number of godfathers were engaged in the innumerable christenings, and named the plants on independent lines. As knowledge grew and the discoveries of genera, species, and varieties became more numerous, these names were found to be very confusing whenever that linking up occurred, which is bound sooner or later to come about owing to the common origin of all plant life.

A large number of botanists have devoted themselves to remedy this evil, but since they usually try to do so on systems of their own, the result has been in too many cases confusion worse confounded. In practice, therefore, we

accept many names simply because the plants have become so thoroughly well known by them that a correction, i.e. any alteration, would constitute a worse evil than the error involved. In British Ferns we have many instances of this kind due to similar reasons. When the varieties first began to attract notice, the finders sometimes named them themselves, and sometimes referred them for that purpose to one of the Fern authorities then existing. Those authorities at first were mostly general botanists, and only later did the experienced Fern specialist step in as godfather, on the strength of his particular acquaintance with the extant varieties. Hence, no recognised system existed, and it was not until a very large number of names had been given on varied lines that it was recognised how many of the plants concerned fell into distinct classes, and how many of one and the same class were named differently, whilst many distinct classes were named similarly. Thus in the now recognised plumose section we have *Polypodium cambriacum*, *Scolopendrium vulgare crispum* and *Asplenium Trichomanes incisum*, as examples of varied names for one and the same condition, while we have on the other hand the one term "pulcherrimum" (itself a defective name, since it does not definitely describe at all), applied to distinct forms of *Polypodium vulgare*, *Athyrium f. femina*, *Polystichum aculeatum*, and *P. angulare*. In Mr. E. J. Lowe's book, *British Ferns*, we have the most comprehensive attempt to classify the varieties throughout, but it may be seen by a glance at the names under the several heads that a very large number might have been named far more appropriately in the light of the greater knowledge subsequently acquired of the general characters of variation.

Every Fern lover who studies the cult carefully knows the best forms by their baptismal names, and would be simply puzzled by a rechristening on up-to-date lines, which we therefore do not advocate. What, however, we do suggest is that all new finds should be submitted to a competent naming centre, especially as such a one now exists in the British Pteridological Society. In this way, at any rate, the evil of higgledy-piggledy naming would be reduced to a minimum, and appropriate names would be given. In my own opinion little good is done by giving an outlandish name to a variety for the sake of distinguishing it from others which it probably so closely resembles as to be only distinguishable by side-by-side comparison.

Thus, to take the cristate forms of the Hart's-tongue as an example. I should classify the bulk of them under the heads of furcans (lobatum), when there are three or four terminal divisions; digitatum, with five to ten pointed divisions; multifurcatum, with a larger number; cristatum, with terminal divisions divided twice or more on flat lines [planes]; corymbiferum, ditto, on bunch lines; and grandiceps, when very heavy tassels are formed.

If branching of the rachis below such terminal division takes place, let the prefix "ramo" be given, and if the whole frond be divided and redivided so that the frond proper disappears, let it be called ramosum, ramulosum, or ramosissimum, according to the extent and character of the branching. These terms as applied to the character of the

tasselling or branching apply to other species as well, and could be preceded by whatever other dominant character the frond presented. They would thus constitute a descriptive name, to which we could attach the finder's or raiser's name if accentuated by some other peculiarity rendering it distinct.

One of the old rules prohibited the re-use of any name previously given, and the consequence was that very often an absolutely fitting name was rejected, and a far less suitable one adopted. In our opinion it would have been far better to use the best name, despite its previous attachment to another plant, and to distinguish by adding the finder's or raiser's name thereto. Opinions differ as to the propriety of attaching Latin or Greek descriptive names to Fern varieties; but we should be very sorry to see this system abandoned in favour of nondescriptive and nondescript names of popular personages, &c., such as prevails with floral forms. There is a distinct difference between the two classes of plants. With flowers such as *Chrysanthemums*, *Begonias*, and the like, such naming is practically unavoidable, owing to the multiplicity of differences in form and tints which often defy clear description. With Ferns, on the other hand, we have only to deal with difference of frond form [and degree of branching], and these lend themselves in the vast majority of cases to a fairly descriptive naming, which is a great assistance to the cultivator. A. f.-f. "Lady Waggles" would convey nothing to the mind at all; but A. f.-f. *curtum cristatum*, or *congestum minus*, instantly calls up an approximate picture in the fernist's mental eye which it would be folly to sacrifice. In the nomenclature of exotic Ferns there has arisen a sort of compromise in this direction, which, however, is very confusing, and promises to become more so, since a number of new varieties are being named as if they were species, e.g., *Polypodium Knightii* and *Phlebodium Mayii*, which are simply plumose varieties of known species. *Polypodium Schneideri* x, that wonderful hybrid between *P. glaucum* and *P. vulgare elegantissimum*, is another misnomer, and should, to be consistent, have been called *P. glaucum elegantissimum Schneideri*. *Polypodium v. elegantissimum*, by the way, affords an example of old-fashioned naming, since it originally bore (and still occasionally bears) three distinct names—viz., *P. v. elegantissimum*, *P. v. cornubiense*, and *P. v. Whytei* (the last, however, but rarely); while we should certainly christen it today "decompositum," which is a description proper. Of the other three names, on the other hand, one is merely laudatory, one indicated locality only, and the third merely one of the finders' names, the main points being thus missed.

My contention is, therefore—1, that the name given should be as closely descriptive as possible; 2, that it should be given without reference to priority as implying monopoly of a good name, adding the finder or raiser's name if distinction justifies it; and, 3, that the name should be submitted to the recognised expert opinion represented by the Committee of the British Pteridological Society, either through the writer or the Secretary, Mr. G. Whitwell, Serpentine Cottage, Kendal; and 4, and finally, that no name should be given except to distinct and good varieties. In this way, at any rate, we may prevent confusion increasing, and confine it as far as possible to the inherited mistakes of the past. *Chas. T. Drury, V.M.H., F.L.S., 11, Shaa Road, Acton, W.*

TREES AND SHRUBS.

SUNBURN.

THE following notes are confined to sunburn as it affects hardy deciduous trees and shrubs. There are many highly ornamental subjects, more particularly those possessing golden and variegated foliage, that lose much of their beauty and effect owing to their leaves being scorched by the sun's rays. The result is an ugly browning of the affected foliage, and in the most serious cases this is followed by premature fall of the leaf, as in the Golden Sycamore (*Acer pseudo-platanus* Worlei) and in one of the golden-leaved Elms (*Ulmus campestris* variety Louis Van Houtte).

Planters are sometimes at a loss to know where to place a subject so as to obtain for it a position in which the plant will show to its greatest advantage, and there are amongst those affected by light of too great intensity many that we can ill afford to do without in the garden, either for massing or as specimen plants. Positions should therefore be selected for them where they will be shielded from the midday sun. Hence the enumeration of those trees and shrubs that most commonly suffer from sunburn may serve as a guide to intending planters. In some few instances—i.e., in the golden and variegated Oaks—the second growth in July and early August obliterates to a large extent the burnt and unsightly foliage on their first or spring growth.

Varieties of the same species exhibit widely different degrees of resistance to the sun's rays, and this is well illustrated in varieties of the common Sycamore. The old variegated form does not burn, or but slightly, whereas the varieties *A. pseudo-platanus* Leopoldi and *A. p.-p.* Worlei are often disfigured, especially is this the case with the last-named variety.

The following is a list of deciduous trees and shrubs most subject to sunburn, those previously mentioned being omitted:—*Platanus acerifolia* Süttneri, *Sambucus canadensis aurea*, *S. racemosa plumosa aurea*, *Corylus avellana aurea*, *C. maxima atropurpurea*, *Fagus sylvatica albo-marginata*, *Fraxinus americana foliis variegatis*, *Castanea sativa aureo-marginata*, *Acer pseudo-platanus Nizeti*, *Diervilla japonica Looymansi aurea*, *Spiraea opulifolia aurea*, *Ulmus Dampieri aurea*, *Æsculus hippocastanum foliis variegatis*. The above list is not intended as a complete one, as many plants are purposely omitted because their liability to sunburn is but slight. *F. H. Matthews, Knap Hill, Woking.*

SPIRÆA THUNBERGII.

Though *Spiræa arguta* is perhaps the more showy plant of the two, *S. Thunbergii* is earlier in flowering and also much hardier, the former being liable to be cut by frost in the bud state, while the latter is generally uninjured, except in the fully open flowers. When fully grown this plant makes a shrub about 3 ft. or so in height and about the same in diameter, with thin, gracefully-arching shoots clothed from end to end with the tiny, star-like, pure white flowers in spring. The leaves are narrow, linear in shape, of a light green hue, and glabrous on both surfaces.

The plant will grow almost anywhere, and provided it has an open, sunny situation, it is practically indifferent as to soil. Young plants of this potted-up in autumn and plunged outdoors until they begin to move in spring, make excellent subjects for indoor decoration if brought on in gentle heat, but they will not stand hard forcing. Cuttings of this variety root readily at almost any time of the year, or old plants can be pulled to pieces, each with a portion of root attached, which soon form good plants. Shoots cut and placed in water in gentle heat just as they show bud will open their flowers and last good for a fortnight or so. *J. C., Bagshot.*

ORCHID NOTES AND GLEANINGS.

ODONTONIA × LAIRESSEÆ.

THIS plant (fig. 1) is, as indicated by its name, a bigeneric hybrid, the resultant of crossing *Miltonia Warscewiczii* with *Odontoglossum crispum*. Of the two parents the hybrid more nearly

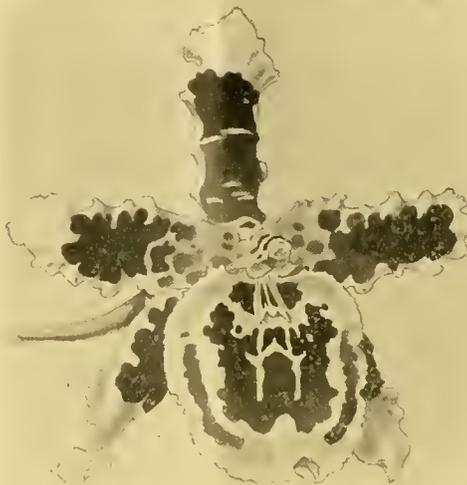

FIG. 1.—ODONTONIA × LAIRESSEÆ: FLOWERS WHITE, TINTED AND BLOTCHED WITH ROSE COLOUR.

approaches *Miltonia Warscewiczii*, but is larger in all its parts. The flowers are white, with the lower portions of the segments tinted and blotched with rose colour, the same colour being also present in the labellum; the crest is yellow. The hybrid was raised by M. A. de Laiesse, Liège, Belgium, who showed the plant at a meeting of the Royal Horticultural Society on June 20, when it was given an Award of Merit.

ODONTOGLOSSUM × VENUSTULUM.

The original hybrids of *Odontoglossum Harryanum*, *O. × crispo-Harryanum*, and *O. ×*

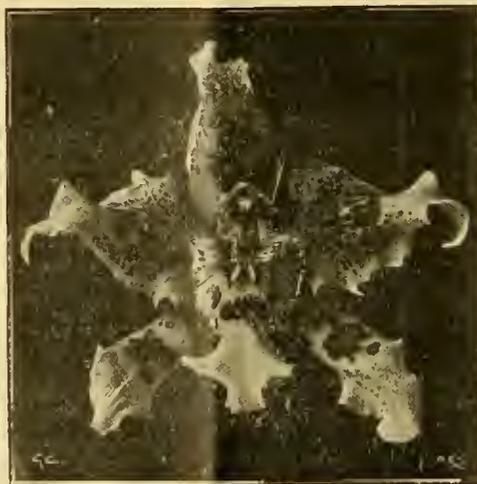

FIG. 2.—ODONTOGLOSSUM VENUSTULUM: FLOWERS LILAC COLOURED BLOTCHED WITH DARK PURPLE.

Rolfæ, are themselves now being used as parents, and some of the offspring have been exhibited at the two last Temple shows by M. Ch. Vuylsteke, of Lochristi, Ghent. One of these was called *O. × venustulum*, and received an Award of Merit in 1904. Its parents were

recorded as *O. × crispo-Harryanum × ardentissimum*, and it was a very handsome flower, heavily blotched with clear purple on a white ground somewhat tinged with lilac (see *Orch. Rev.*, 1904, pp. 201, 202, fig. 31). This year another form of it has appeared, which is represented in the annexed illustration (fig. 2), reproduced from a photograph taken by Mr. E. C. Hart. It is an exceedingly handsome flower, of very graceful shape, and the copious blotches are of very dark purple on a lilac ground. The flower has retained a large amount of the original *O. Harryanum* influence, and the use of this species by the hybridist is introducing quite a new type of *Odontoglossum*, which promises to play a very important part in Orchid collections in the near future. *R. A. R.*

LISSOCHILUS KREBSII.

This pretty and free-growing South African Orchid has flowered in several collections this season. At the meeting of the Royal Horticultural Society on May 23, the Rt. Hon. Lord Auckland showed a fine inflorescence of the typical species. The flowers, which were 2 inches across, had greenish sepals freckled with purple. The petals, nearly an inch across, form the showy part of the flower, the lower side or face being cream-white and the upper surface buttercup-yellow; lip orange with greenish side lobes.

Sir Chas. W. Strickland, Bt., Hildenley, Malton, Yorks, also sends flowers of the variety *purpuratus*, collected near Buluwayo. In this variety the side lobes of the lips are purple. Now that these handsome South African *Lissochilus* are grown as greenhouse plants they are giving good results.

Lissochilus Graefei of Kranzlin, in *Reichenbach Xenia Orchidaceæ*, iii., t. 272, and in *Gardeners' Chronicle*, June 11, 1892, p. 719, and June 10, 1893, p. 684, is a very close ally of *L. Krebsii*.

ORCHIDS AT MR. H. A. TRACY'S.

Odontoglossums, *Cypripediums*, *Cattleyas* and *Lælias*, and other showy Orchids are always well represented in Mr. Tracy's Orchid and Bulb Nurseries in the Amyand Park Road, Twickenham. This year the show of varieties of *Odontoglossum crispum* has been unusually good and prolonged, and even on June 20 there was a nice display of them, together with forms of *O. × Andersonianum*, *O. luteo-purpureum*, and other species. *Cattleya Mendeli* and *C. Mossiæ* are especially good, among the former being the true *C. Mendeli formosa* with white sepals and petals, and fine labellum richly marked with orange colour in the throat, and a light marking of rose colour in front. The blush-white forms of *C. Mossiæ* also are fine in shape and delicate in tint, and *C. Aclandiae*, *C. luteola*, and others are in bloom. Also good *Lælia purpurata* and *L. tenebrosa*.

The collection now includes a fine set of hybrid *Cattleyas* and *Lælio-Cattleyas*. The showiest at present are *L.-C. × Canhamiana* and *L.-C. × Aphrodite*, one plant of the latter flowering for the first time being very fine, the rich violet-purple-coloured lip contrasting well with the clear white sepals and petals.

The newly-arranged front house has a good show of *Cypripediums*, among which the great variation in the forms of *C. Curtisii* is noticeable. Among the *C. callosum* also is a very distinct and peculiar form, with flowers of a thicker texture than usual, and with a yellowish ground colour, the markings being much darker than in ordinary varieties.

Also in flower were *Renanthera lutescens*, *Dendrobium MacCarthiae*, *Cochlidia Noezliana*, and a bright lot of Brazilian *Oncidium*s and Colombian *Masdevallias*. A basket of *Utricularia montana*, which seems to thrive best in the Orchid-house, has a profusion of large white flowers with yellow centres.

THE BEAUCHAMP EUCALYPTUS
(?=*E. CINEREA*, *f. v. M.*)

SOME time since, Messrs. Treseder & Co., of Truro, obligingly sent us specimens of a Eucalyptus called by them *E. Beauchampiana*. Being unable to verify this name after prolonged search, we applied to Messrs. Treseder, who told us that the name was of their own coinage. We then set to work to try to ascertain what the species really was; but as we had only foliage, and that of one kind, before us, it will be easily guessed by those who have to deal with the identification of the species of this genus that the task was not an easy one, and it is with some hesitation that we refer it to *E. cinerea*. This species is not included in Müller's *Eucalyptographia*, but finds a place in

the species is included in the rich collection of the late Mr. Rashleigh at Menabilly, but as he was in frequent correspondence with us on the various species of this genus that he had in cultivation, and did not mention it to us, we are inclined to think that he did not possess this particular variety, or that he had it under some other name.

NEW OR NOTEWORTHY PLANTS.

IRIS JUNONIA, SCHOTT AND KOTSCHY.

I AM indebted to Mr. Siehe, of Mersina, for the large, handsome bearded Iris which he has introduced into cultivation as *I. Junonia* (Schott and Kotschy), Mr. Siehe having found it, if I remember rightly, in the original habitat.

I ought, of course, when I ventured to burden the world with a new name, to have realized that a Cilician plant might possibly be found in Cyprus, and to have carefully compared my plant from Cyprus with the description of *I. Junonia*; but I did not, and the mischief is done. I can now only offer an apology, and suggest that my *I. cypriana* ought to be called *I. Junonia* var. *cypriana*. The two plants are unlike enough, through the difference in colour, to deserve, for garden purposes, distinctive though not specific names.

By the way, Siehe's plant should be called *I. Junonia*, and not, as is sometimes done, *I. Juno*. The latter name has long been used for a division of the genus *Iris*. *M. Foster, Shelford, June 5, 1905.*

WISTARIA INVOLUTA = DERRIS INVOLUTA.

In the note accompanying my description of *Wistaria involuta* in these columns (August 27, 1904), the artificial nature of the limits between certain tribes of Leguminosæ was briefly commented on, and it was remarked how closely some genera of Dalbergiæ, e.g., *Lonchocarpus*, approached *Millettia* and *Wistaria*. This relationship has been strikingly borne out. Since the description appeared, the plant of *Wistaria involuta* has fruited; the pods are seen to be flat, indehiscent, and one-seeded, with a narrow wing along the upper suture. From their structure it is now evident, as was kindly pointed out to me by Lt.-Col. Prain, the authority on Indian Leguminosæ, that *W. involuta* is a *Derris* of the section *Brachypterum*, and must therefore be known for the future as *Derris involuta*. It appears that in the absence of fruit it is almost impossible to distinguish *Millettia* and *Wistaria* from *Derris*.

The species most nearly allied to *D. involuta* seems to be the Indian *Derris scandens* (*Dalbergia scandens*, Roxburgh), which differs principally in the wings of the corolla, which are auricled and densely ciliate at the base, as is well shown by Wight (*Icones Plantarum India Orientalis*, t. 275).

An interesting fact, hitherto unremarked, is that the Australian specimens quoted by Bentham (*Flora Australiensis*, ii., p. 272) under *D. scandens* are certainly distinct from that species. They resemble *D. involuta* in having the wings of the corolla subtruncate and glabrous at the base, and though they differ from the latter in their rather smaller flowers and shorter and more appressed hairs, their flower-structure is so similar that I have little hesitation in referring them to *D. involuta*. *T. A. Sprague.*

FLUED FRUIT WALLS.

EVERY gardener who has proved the utility of fruit-tree walls that can be rendered warm by artificial means, so as to ward off frost when the trees are in flower and for a few weeks later, and in wet, cool seasons to hasten and complete the maturation of the summer's shoots in September and October, would desire to possess them. Usually it is the so-called south wall—really the south side of the north wall of a garden so surrounded—which is flued; and this, in an entirely walled-in garden, would also mean the south side of the opposite wall if there is cultivable land on the outside of the walled-in space, as is usually the case in country gardens.

Owing to the cheapness of fuel, walls of this description are more common in north-country gardens than in the southern or midland shires; moreover, the necessity for their construction is greater in the former owing to the severity of the frosts in the spring months and the coolness of the summers, although the extra length of the days during the summer and early autumn, and the consequent larger amount of sun-heat imparted, if it be less ardent than in the south in the generality of years, is a sufficient compensation.

FIG. 3.—THE BEAUCHAMP EUCALYPTUS (*E. CINEREA*?).

Bentham's *Flora Australiensis*, iii., 239. Mr. Worthington Smith's drawing sufficiently indicates the appearance of the specimen, so that we need only add that the wiry branchlets are purplish in colour; the leaves, some alternate, others opposite, are glaucous and studded with glands on both surfaces, and that the veins are purplish in colour. *E. cinerea* is a native of New South Wales.

The tree may be called in gardens the Beauchamp Eucalyptus, but care should be taken not to create confusion by using a Latin name until the identity of the species is rendered certain. Messrs. Treseder tell us that it is one out of many raised by them. It is a stately tree with red bark. It alone has proved itself hardy, "having withstood 20' of frost. Even the young growths do not get touched in the severest weather." We need hardly say that this is an excellent character to give to an Eucalyptus. We do not know whether

I have not had an opportunity of seeing the plant in flower until this year; but having now done so I can say that while it answers so completely to the original description that there can, I think, be no doubt as to its being *I. Junonia*, it is at the same time identical in every way, except in colour, with an Iris which I obtained from Cyprus some years ago, and which I described (*Gardeners' Chronicle*, August 18, 1888, p. 182) as *I. cypriana*. In *I. Junonia* the blade of the fall is of a rich red-purple, in *I. cypriana* of a blue-purple colour. In *I. Junonia* the standard is of a light red-purple, in *I. cypriana* of a light blue purple. In *I. Junonia* the beard is orange, in *I. cypriana* yellow. And the brownish veins on the creamy-white ground of the claw of the fall are bolder and coarser in *I. Junonia* than in *I. cypriana*. Otherwise in every respect (though I have not yet seen the ripe capsule and seeds of *I. Junonia*) the two plants are quite the same.

It may be said that the gardener who has not the advantage of a warmed Peach wall may in one year in five obtain a fair crop of fruit on his trees, whilst another who has a warmed wall is sure to get a good crop every year.

The writer knew a north-country gardener who for thirty years never once failed to secure a good crop of Peaches, Nectarines, Apricots, and Brown Turkey Figs from such a wall.

The usual practice is to light the fires as soon as the flower-buds begin to show colour, and so to manage the stoking as to produce a mild warmth in the bricks forming the southern face of the wall. In order to do this on nights likely to be frosty, the various furnaces should be started at dusk and the fuel kept gently burning till 11 P.M., the brickwork once well warmed retaining its warmth till sunrise in sufficient degree to ward off all danger from frost. Under this sort of treatment the blossoms open kindly, and the growth of the shoots proceeds without check from cold weather. During cold days it is even sometimes desirable to keep the fires going the entire day in order that cold may not check growth.

Peach and Nectarine trees on warmed walls suffer much less from leaf-curl and blister than those on unheated walls. Of course there are a few disadvantages and evils attendant on the use of flued walls, as is only to be expected; but the careful gardener can easily surmount these. There is a notable and early increase of red-spider on the foliage of the Peach and Nectarine-trees, and the soil becomes drier at the foot of the wall, both of which difficulties can be overcome by the use of clean water applied with the garden-engine as soon as the fruits have reached the size of Haricot Beans; and if the water finding its way from the surface of the wall be not enough to moisten the border, the watering-pot must be called into use. This syringing of the foliage of the trees should be carried out till the fruit approaches the ripening period, which will vary in the different varieties, and cannot therefore be indicated here with accuracy.

As compared with blinds of canvas, "frigidomo," Spruce Fir coverings, or glass copings, portable or otherwise, the advantages remain with the flued wall, inasmuch as spring frosts of any probable severity can be warded off, the bad effects of showers of sleet and hail nullified, and the growths matured in cool summers. The flued-wall also affords a capital means of protecting and forwarding Tomato plants. Where vacant spaces occur between the trees, early Cauliflowers and Lettuces may be planted within a foot of the wall wherever the depth of soil allows of this being carried out without injury to the roots of the trees.

The period during which fires may be needed will vary with the latitude, and in a general way it may be said to continue from the last week in March to May 20, therefore eight weeks. The number of furnaces required for a wall 120 yards in length would be six, each sending its smoke 10 yards to the right and left in a flue 3 to 4 feet high, returning on itself twice before it emitted the same to the open-air, by means of a low chimney-pot made directly over the furnace.

As a readily accessible means of clearing the flues of soot there should be openings closed with iron doors, made about the middle of each limb of the flue. A flue may go safely without clearing the soot out of it for from four to six years, according to the kind of fuel burned; but a longer period than six years is not advisable, for should a large quantity of soot become ignited much damage might accrue to the trees, more especially if these were secured close to the surface of the wall with wires, nails, or studs.

The quantity of coal required per furnace is about half a ton per week, and if slack coal be burned the cost per furnace would be about

2s. 6d. per week. The total cost of fuel for the period named would therefore come to £6 for ensuring a full crop of the various fruits named.

The flue as compared with hot-water heating is the more economical, the serpentine course and length of a flue extracting the whole caloric from the fuel consumed, whereas in a boiler much of the heat escapes up the chimney. Moreover, the hot-water apparatus involves a great initial outlay, and repairs are difficult to effect owing to the confined space in which the pipes must be laid.

In conclusion it may be stated that the north side of a flued Peach-wall should be constructed of stone, cyclopean or dressed, or of 9-inch brickwork; and the front or south side of $4\frac{1}{2}$ -inch brickwork, and the bottoms of the flues of 9-inch work; and the wall should be furnished with a stone coping overhanging on the south side about 4 inches. The brickwork at the back of the fireplace and for 4 feet on each side should be made three bricks thick. The furnaces should be provided with furnace and ashpit doors, so as to have the draught under control. *F. Moore.*

LEAVES FROM MY CHINESE NOTE-BOOK.

ICHANG TO KAITING.

(Continued from p. 384.)

April 29.—We started at 5 A.M. and reached the foot of the Yeh-Tan at 8.30 A.M.; here we moored below ten junks. Some distance below the rapid I counted thirty-six junks tied up waiting their turn to move up to the foot of the rapid. As a foreigner I was entitled to precedence. The Yeh-Tan—Wild Rapid—well deserves its name. I have never seen it so bad, yet next month, they say, it will be much worse. A night I once spent tied up at the foot of this rapid will long be remembered. Although I saw the boat securely lashed, its creakings and bumpings and the roar of the rapid prevented sleep. Many were the times I sprang up from a fitful doze with a start, thinking the boat had broken her lashings and was being hurried to destruction. I vowed I would never again sleep at the foot of a rapid, but I have had to do so on many occasions since.

I watched the junks being hauled over until I grew tired and dizzy. The roar of the rapid was deafening, and was heightened by the yellings of hundreds of trackers as they strained and tugged in their endeavour to haul the boats over. Of the ten junks in front of me three were wrecked.

Having seen these boats wrecked I had some misgivings about my own, when at 3.30 P.M. our turn came. My captain chin-chinned, joss crackers were exploded, a little wine and rice were thrown over the bow, joss-sticks were burnt, together with candles and some paper cash—in short, every rite necessary to appease the terrible water-dragon was strictly observed. All went well. With three lines out and a hundred men tugging away, she was over safely in twenty minutes. I watched from the shore, and breathed freely when she was safely moored in still water once more.

Immediately my boat was over a small boat with five men in it attempted to cross. Something went wrong, and she capsized; two men disappeared immediately; the three remaining clung to her as she was washed down-stream. Several lifeboats put off immediately, and succeeded in saving these three men.

The capsizing of this boat was taken little notice of, and the people were busy hauling over the next boat immediately afterwards. One can but admire the skill and daring of the men who navigate boats over such places as this. The slightest mistake in any direction is fatal. Undeterred by wrecks in front they ply their calling, laughing and jesting as if it were the simplest

of matters. They know that daily the dragon demands his toll of human life, and fully expect that the time will come when they themselves will be called upon to pay it. Thus their fatalism makes them indifferent to the dangers. After getting safely over I was quite willing to accede to the custom of giving the crew a feed of pork. As I sat writing they were gorging on the front of the boat, and were mightily pleased with themselves. Their merry laugh is much pleasanter to my ear, though it disturbs one's thoughts, than the sullen roar of the rapid a mile below. In a short stroll after the boat was over the rapid, I noted a few plants of passing interest, chief of which were *Pteris palmata*, *Berchemia hamosa*, *Trachelospermum jasminoides*, and *Ehretia macrophylla*. The latter is rather a striking plant. It is a small tree, 15 to 30 feet in height, with large, broadly ovate, hispid leaves. The flowers are white, with a powerful odour, and are borne in corymbs. The fragrance somewhat suggests that of the Orange. The wood is light and tough, and used for making carrying-poles. It is a warm temperate plant, and I have not met with it above 2,000 feet alt.

April 30.—We started at 5 A.M., and, favoured with a strong, fair wind, made rapid progress. We crossed the Niu-kou rapid (ten miles on) at 10.35 A.M. A rock in the middle of the stream is the principal danger at this rapid. H.M.S. *Woodlark* got caught by the current and had her bows stove in by this rock in the first ascent of the British gunboats to Chung-king. About half-way between the Yuh-Tan and this rapid a patch of cliff on the left bank is covered with *Opuntia Dillenii*; *Pinus*, *Plum*, *Peach*, and *Aleurites cordata* are abundant. Around the Niu-kou rapid much coal is worked; outcroppings of coal occur right on the foreshore, but the quality is poor.

At 1.30 P.M. Patung city was passed, and soon afterwards we ascend with difficulty a nasty rapid. At 4 o'clock we entered the "Wushan," the longest of all the gorges. We moored at 7 P.M. some six miles from the Hupeh-Szechuan boundary, having covered thirty-five miles in the day.

The Wushan gorge is some twenty-five miles long. The entrance is narrow, and wears a gloomy and forbidding aspect. The cliffs equal and even surpass those of the other gorges in height, and are for the most part vertical and inaccessible, with scarcely a tracking path anywhere. The river is narrowed to about three hundred yards. Sailing through this silent gorge, walled in on all sides by such stupendous cliffs, one feels oppressively small.

The flora continued most interesting. Near our moorings, high up on the tops of the cliff, was a nice patch of woodland, the most noticeable tree being the *Nanmu*, *Machilus nanmu*. When covered with forest, how much more magnificent the scenery must have been! Amongst the rock on the foreshore I gathered *Cynanchum verticillatum*. Its pretty white flowers are highly charged with a viscous nectar. Captured in this I noted many small flies and ants—unwelcome guests and punished accordingly. The leaves on this plant are not always verticillate. I gathered one specimen with alternate, opposite, and verticillate arrangements on the same shoot. Associated with this species, but not in flower, was another species with opposite leaves.

A very attractive shrub was a species of *Pyrus* with linear-lanceolate leaves and corymbose inflorescence. Bushes of our lovely friend, *Chionanthus*, were dotted all over the cliffs. *Ficus infectoria*, too, was abundant on the cliffs; its leaves, just falling, were of a lovely golden-yellow colour. Amongst the rocks on the foreshore the pretty *Rehmannia Piaseckii* was common. But the showiest plant of the day was *Reinwardtia (Linum) trigyna*, familiar as a pot plant in our greenhouses. It is a pity

PLANT NOTES.

ECHIAM WILDPRETHII.

THIS striking Canary Island Echium has recently made a fine show at Kew (see fig. 4), and was also exhibited at the Temple Show. It is a rather recent introduction to gardens, having been sent to Kew by Mr. Wildpret, Curator of the Botanic Gardens of Oratava, Teneriffe, under the name of *Echium candicans*, but on its flowering in 1897 it was seen to be quite different, and it was afterwards illustrated in the *Botanical*

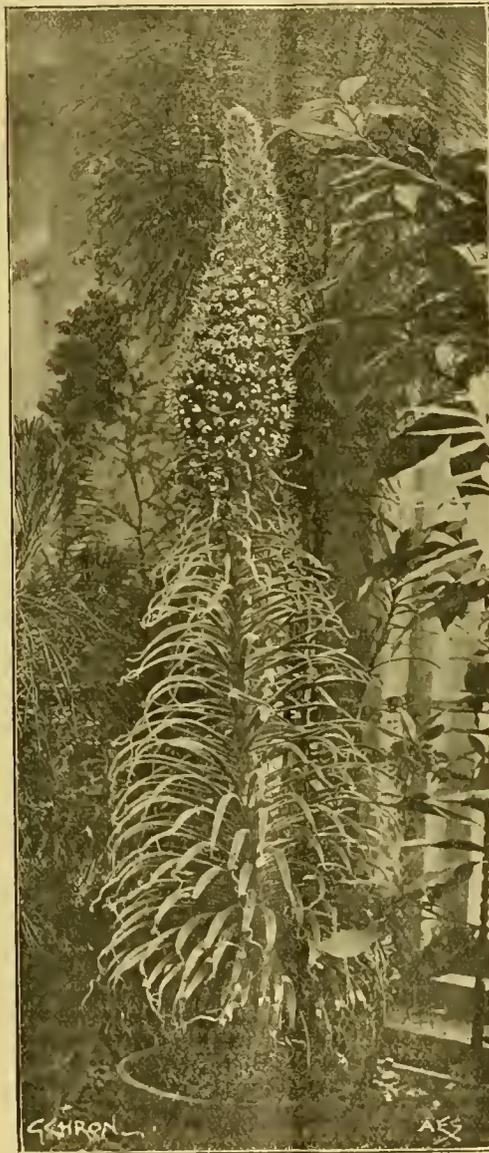

FIG. 4.—ECHIAM WILDPRETHII: FLOWERS ROSE-PINK. (Much reduced.)

Magazine (t. 7847) under the name of *Echium Wildpretii*, after its discoverer. It is a striking plant, as the photograph by Mr. E. C. Hart shows, and its numerous flowers are of a pleasing rose-pink, which contrasts effectively with the silvery-green foliage. It is a biennial, forming the first year a dense rosette of long, narrow, silky leaves, after which the stem rapidly lengthens, ultimately forming a dense thyrseid panicle of flowers as shown. In most respects the species is allied to *E. callithyrsus*, Webb, which however forms a sturdy bush, and has bright blue flowers. It is said to be of fairly easy culture, requiring plenty of water during its growing season, from February to August, but a very sparing supply during the rest of the year.

Some twenty species of *Echium* are found in the Canary Islands and Madeira, and are among

the handsomest elements of the indigenous flora. *E. candicans* is a magnificent plant growing in grand masses on moist banks at some 2,000 feet altitude and producing dense panicles some 20 to 30 inches long of bright-blue flowers (*Botanical Magazine*, t. 6868). *E. fastuosum* is one of the most striking objects of the rock *Echiums* of the Madeira littoral. It is a perennial, rising to some 5 or 6 feet high, and has numerous inflorescences 6 to 12 inches long of pale-blue flowers, which are highly attractive to bees and butterflies. *E. simplex* is a remarkable Teneriffe species, producing a simple unbranched stem from 8 to 12 feet long tipped by a great inflorescence of white flowers. It is a striking object on the sea-cliffs and is also cultivated in gardens. Here they require protection, except during the summer, but are well adapted for pot-culture, and form very striking objects under suitable treatment, as the illustration shows. R. A. R.

EXACUM MACRANTHUM.

This plant is one of the most beautiful blue-flowering subjects in cultivation. It is a native of Ceylon, and will succeed in a warm greenhouse or stove. It is compact in habit, grows to about 18 inches in height, and has neat and pleasing foliage. It flowers freely and when in bloom presents a lovely appearance. The flowers are about 2 inches in diameter and of a rich indigo-blue, with striking yellow-coloured anthers. Cuttings of the young growths inserted around the edge of small well-drained pots filled with light sandy soil placed in heat, either in a forcing house, propagating pit or frame, and watered through a fine spray distributor to settle the soil, will quickly form roots and soon be ready for potting singly into small 60-sized pots. For this shift the compost should be composed of two parts fine peat and leaf-mould free from worms, and one of fine sandy loam, with a liberal addition of sharp sand, the whole being well mixed together before being used. The soil should be made moderately firm about the roots of the young plants. Afford water carefully as recommended above, and maintain the soil about the roots in a uniformly moist state during the whole period of active growth, damping over the foliage with tepid water morning and afternoon on bright days in order to promote a free healthy growth. When the flowers are about to open the application of overhead moisture should be discontinued. H. W. Ward.

COLONIAL NOTES.

HONGKONG BOTANICAL DEPARTMENT.

OUR Hongkong correspondent, Mr. S. T. Dunn, has forwarded a copy of his very interesting Report on the Hongkong Botanical and Afforestation Department for 1904, from which we have taken the following extracts:—

Square Bamboos (*Phyllostachys quadrangularis*, Rendle).—In March a box of this Bamboo was received from Mr. Mortimore in good condition. The clumps were at once planted in various situations, and all are doing well. The Bamboo grows on the island of Wenchow. This is a new record of the species for the Province of Chekiang, and connects the two previously-known habitats in Kiangsu and Fokien.

Gingko biloba, L.—In the *Index Floræ Sinensis*, ii., 547, Dr. Masters quotes Mrs. Bishop as saying that she had met with several fine specimens of *Gingko* in the magnificent forests which surround the sources of the Great Gold River and the smaller Min in Szechuen. It is probably safer at present to omit the *Gingko* from the Chinese indigenous flora. The fact probably is, as Solms-Laubach has pointed out, that the *Gingko* has long outlived its natural age in the flora of the earth, and has only been preserved from

it cannot be seen as it occurs here and in the gorges generally. Amongst loose, rocky debris it is peculiarly at home, the drier and more stony the ground the happier it is. It seldom exceeds a couple of feet in height. It is a common sight to see hundreds of yards of the river-bank one mass of its lovely yellow flowers. March is the best month to see it in, however. This plant is strictly speaking a xerophyte, and ought under cultivation to be treated as such. The day's journey was full of interest, and the variety of scenery charming. I had a long spell in my lifeboat, and enjoyed it immensely, the comparative absence of noise being very refreshing. The wild chant of the coolies, keeping time as they work the sculls, is not unmusical when mellowed by distance, but after a short period it becomes wearisome by close contact. E. H. W.

(To be continued.)

KEW NOTES.

GRAMMANGIS ELLISII, Lindl., *Botanical Magazine*, t. 5179.—This magnificent Orchid is flowering in the Orchid-house. Although introduced nearly fifty years ago, it is but rarely met with at the present time. It is a plant with large, square, glaucous pseudo-bulbs, often measuring from 9 inches to a foot in length; the leaves, which are generally about five in number, arise from near the top of the pseudo-bulbs; they are about 18 inches in length by 2½ inches in breadth. The inflorescences are developed with the young growths, sometimes only a single spike, but generally there are two from the one growth, as in the present instance. The largest spike is 2 feet in length, arching as in *Odontoglossum crispum*, and has twenty-four flowers, each of which measures 2½ inches in diameter. The sepals are broad and fleshy, having a yellow ground, which is barred and blotched with brown. The petals are much smaller than the sepals, white at the base and rose-coloured and brown towards the tips. The lip is rather smaller than the petals, light red in colour, with many white crests. It is a native of Madagascar, and is one of the most beautiful Orchids in cultivation.

GERBERA ELSÆ.

Three years ago a small plant under this name was received from Max Leichtlin, of Baden-Baden. Since that time it has been planted in a border in a cool-house, where it has grown into a nice compact plant, and is now flowering for the first time at Kew. It has simple leaves 9 inches in length and 3 inches in the broadest part, having coarsely crenate margins. They are subcoriaceous in texture, with a silvery tomentum on the reverse, and also on the margin. The flower-scape is about 18 inches in height in the present instance. The ligulate flowers are of a very bright blood-red colour, very broad, acute at the apex, and closely arranged. The disc flowers are light red with bright yellow anthers. The composite inflorescence has a diameter of 2½ inches. It is by far the most handsome of all the *Gerberas* grown at Kew.

DISAS.

A good show of these terrestrial Orchids is now to be seen in the *Odontoglossum*-house composed of the following species and hybrids:—*D. racemosa*, *D. tripetaloides*, *D. kewensis*, *D. langleyensis*, and *D. Premier*. *D. grandiflora* is promising well for a good display later on. W. H.

MUSA PERRIERI.—This is a newly-discovered species of *Musa* from Madagascar, described by M. CLAVERIL in the *Comptes Rendus*, June 13. The base of the stem is dilated into a thick bulb, from which no suckers are given off. The leaves are deciduous during the dry season. The natives make use of the seeds as beads, and utilise the borders of the leaves as tying material.

extinction by the care of the Chinese priests. The tree is without near relations in our extant flora, and when Mr. Archibald Little described to me in 1903 a most remarkable tree, like Ginkgo, which he had seen near Chengtu, I begged him, if again in that neighbourhood, to revisit the spot and secure details for investigation. Accordingly when Mr. and Mrs. Little were near Chengtu in April of last year they most kindly made a détour of 140 li, took several photographs of the tree, and sent them to Hongkong with an interesting description. The tree proved to be not a variety, but a very old specimen of the true Ginkgo covered with the peculiar outgrowths to which the species is subject in old age. The outgrowths take the form of cylinders, varying from a few inches to several feet in length, and about 4 inches thick, pendent from the trunk and lower branches. Enquiry was made from Professor Matsumura, of Tokyo, as to the occurrence of similar trees in Japan, and he most courteously sent me a copy of Fugu's paper on the subject, in which the occurrence and origin of the outgrowths are described in detail. They are considered to be merely malformations, and are commonly met with on old trees in Japan.

Flora of North-east Kwantung.—In September and October three Chinese collectors were despatched to Hoi Fung, about 100 miles up the coast, with instructions to proceed inland to the Lien Fa Mountains to explore these, and then, crossing them, to make collections on the further side round the sources of the Han. They succeeded in carrying out this programme, and brought back an interesting collection. Among the most important discoveries was that of *Manglietia Fordiana*, Hemsl., only previously known as a single tree in Hongkong, and that in a precarious state owing to its failure to propagate itself or to admit of artificial propagation. The tree was found in fruit, and seeds were brought back, some of which were sent to Kew. The collection is not yet completely worked out, but enough has been done to show that the flora of these mountains is an extension of that of the Lo Fou Mountains, well known from the labours of Sampson, Faber, and Ford. A large number of the interesting species discovered there by these collectors are repeated in Lien Fa Shan. The numbers for this collection in the Colonial Herbarium are from 1535—1684, and 1825—1894.

China New Year Shrub (*Enkianthus quinqueflorus*).—This shrub, which is one of the most beautiful of all our rich shrub-flora, has yearly been becoming more and more scarce on the hills in consequence of the amount that has been cut by the Chinese at each new year to sell for decorations. Attempts have been made to check the destruction of the tree.

Pollard Pine-trees.—During the Forestry Licence rounds a system of cultivating the local Pine (*Pinus Massoniana*) was met with at Lung Ko Tan, which is, so far as can be ascertained, unique. In this method the same advantages are aimed at as by the well-known European system of pollarding. But the pollarding of coniferous trees seems to be unknown in Europe. The exact method employed with the Pines here is as follows: At 10 years old, when the tree is about 12 feet high, the top half is cut off. After 5 years more the lower branches are cut off. Shoots soon appear from the cut parts, and these are cut every 5 years, together with the upper remaining internode. This tree produces annual whorls of branches, until after 20 to 25 years, the whole is used up.

THE SOUTHERN ISLANDS OF NEW ZEALAND.

Dr. Cockayne has published in the *Transactions of the New Zealand Institute* an account of his trip in midwinter (July) to the Auckland, Campbell, Antipodes, and Bounty Islands, with details relating to the geology, climate, and flora

of those islands. In the Auckland Isles there are forests of *Metrosideros lucida*, and elsewhere of *Olearia Lyalli*. The details of the flora of the several islands are of great interest, and bear out Sir Joseph Hooker's theory of the previous existence of a much greater extent of land in the Southern Hemisphere, whilst the occurrence of a milder climate than now prevails has been attested by the recent discoveries of fossil plants in the antarctic regions. The identity of the flora of all the antarctic islands, from Cape Horn to Kerguelen's Land, is explained under this supposition. One curious feature in many of these Southern plants is the great diversity of foliage in the same plant, which leads to the inference that the plants are not in full harmony with their surroundings. *Discaria Toumatou*, cultivated in moist air, no longer produces spines. Many species of *Raoulia*, *Veronica*, and *Carmichaelia* will revert to the seedling form by cultivation in moist air or feeble light, or, under the same conditions, the seedlings in some cases will never assume the adult form. The paper is accompanied by a complete list of the plants inhabiting the Southern islands, by an extended bibliography, and a series of illustrative plates.

"THE WEST INDIAN BULLETIN,"

vol. vi., No. 1, is occupied with further details of the Proceedings of the Agricultural Conference, 1905. These relate especially to the growth of Sugar-cane and of Cacao, together with valuable notes on the fungoid diseases and insect pests which attack those crops.

ONTARIO AGRICULTURAL COLLEGE.

The thirtieth Annual Report, among many details of local importance, contains valuable reports from the several Professors. The section on the fungi and insects attacking fruit-trees is particularly serviceable, hence we trust we may before long see it in a form more generally accessible.

CAPE GOVERNMENT HERBARIUM, CAPE TOWN.

"Professor MacOwan announces to the circle of friends in correspondence with this Herbarium that he retires from his office of (Government) Botanist at the end of June. The Government does not at present intend to appoint a successor, but the collection will remain under the competent charge of Miss S. Treleaven, who has had ten years' experience therein, and to whom correspondence respecting its contents may be addressed. For administrative purposes the Herbarium will not, as heretofore, be under the Agricultural Department, but will be affiliated to the South African Museum. Professor MacOwan removes to Grahamstown, and will unofficially assist in the Herbarium of the Albany Museum in that city, under the charge of Dr. Selmar Schönland, M.A." Botanists will be grieved to hear of the resignation of Professor MacOwan, and still more at the intimation that the office of Colonial Botanist will not be filled up. The circumstances of the time would, we should have supposed, have rendered the services of such an officer specially important.

"FLORA CAPENSIS."

We note the appearance of another instalment of this publication, Vol. IV., Sect. 1, Part 1. It includes a portion of the order Ericaceae, contributed by Messrs. H. Bolus, E. Guthrie, and N. E. Brown. Though Heathbs are not so popular in cultivation as formerly, they are still important numerically and otherwise. The authors had a long and most difficult task in the preparation of this volume, as, though diffused over a comparatively small area, the number of Cape Heathbs of the genus *Erica* alone amounts to 268 species. Their determination presents great difficulties, and the preparation

of satisfactory analytical keys must have been a cause of much perplexity. It is not unlikely that some of the species hybridise freely, and thus would increase the difficulty. It is regretted that the death of Professor Guthrie occurred before his share of the work on this publication was completed.

FLORISTS' FLOWERS.

SOME NEGLECTED ASTERS.

THE most popular of the annual Asters are undoubtedly those of the Victoria and the Comet types. They dominate in gardens and on the exhibition table. Both types are of easy development. If good strains are obtained, and they are cultivated in a soil of sufficient heart, with good attention, fine flowers will result. In the West of England exhibitions, as at Taunton, Trowbridge, Bath, &c., stands of the before-mentioned varieties, and the highly-refined quilled forms, cover large spaces of tabling, though there is reason to fear the quilled section is ceasing to be as much grown as it formerly was. The explanation is that in order to have the quilled Aster in the finest character it needs high and careful cultivation, and a sacrifice of time that many gardeners are unable to give. Another fine and distinct Aster appears to be going out of cultivation, in this country at least, namely, Truffaut's Peony-flowered Perfection, the French Aster of seed catalogues. This is a true incurved Aster, and holds about the same relation to the flat-petalled Comets and Victorias as the incurved *Chrysanthemum* does to the Japanese.

There was a time when schedules of prizes contained a class for French Asters, meaning Truffaut's type; but, as it is an Aster that must be given good cultivation before it will produce flowers in perfection, it has unfortunately gone down before the flat-petalled varieties, which are grown more easily. Yet there are in Truffaut's Asters colours scarcely to be met with in the other types. It is a stiff-growing plant, producing its flowers on rigid stems, and well suited for cutting. The once popular crown-flowered variety, with its central disc of white and broad, showy margin of some dark shade, has also fallen out of cultivation to some extent, charming as the blooms are. Good cultivation is required also in the case of the Crown variety to secure full-centred flowers. The Ostrich Plume Aster makes an excellent decorative plant for the garden and for cutting.

GOLD-LACED POLYANTHUS.

Several weeks ago I received a box containing bright and effective gold-laced Polyanthus flowers from Rothesay. For border decoration they were excellent subjects. The strain was of vigorous growth, the flower-stems being stout, and the frusses large and bold. Judged by the standard of a variety like *Cheshire Favourite*, it is at once seen that they are deficient in the necessary florist's properties. Varieties with clouded centres were prominent, the golden zone round the eye being stained with deep orange, and having the colour of the "lacing" quite distinct from the tint of the centre, while in not a few cases the lacing did not extend through the segments to the centre of the flower. Silver lacings shading to stained gold centres were among them, imparting a confused appearance to the flowers. There is so much misconception as to what really constitutes quality in a gold-laced Polyanthus that I have set down the foregoing defects as showing what should be avoided by those seeking to select a really fine strain. At the same time I am well aware that seeds from a good strain of gold-laced Polyanthus may be sown, and not one in five hundred realise expectations. R. D.

BOOK NOTICE.

CHOICE FERNS FOR AMATEURS. By George Schneider (Upcott Gill).

We had imagined that the public taste for Ferns had materially abated of late years. Nevertheless the exhibits at the Royal Horticultural Society give frequent evidence that for certain kinds of Ferns the feeling of the public is as keen as ever, and we have only to glance at the shop-windows of the florists to obtain further testimony to the like effect. Mr. Schneider's new book, an abridgement of his former one, indicates that these beautiful plants are attracting an increased share of attention. If they lack the brilliant colouration of the flowers of some plants and of the foliage of others, they have yet a

FOREIGN CORRESPONDENCE.

M. TRUFFAUT'S NURSERY AT VERSAILLES.

M. TRUFFAUT is a well-known cultivator of stove and greenhouse flowering and decorative foliage plants. The climate so near Paris is sufficiently good to enable M. Truffaut and other nurserymen to plant out some of the less tender of these species towards the end of May, in order that the plants may make the whole of the summer growth out-of-doors. At that time many thousands of young plants of *Rhododendron* (*Azalea*) *indicum* were removed from the frames and planted into beds composed entirely of peat obtained some little distance away. The plants were about 1 foot high, with "heads"

Ficus plants are put out after the *Azaleas* have been planted, or at about the beginning of June. Whilst this work was going on outside, we saw in the glass-houses a collection of plants of varying degrees of interest to Englishmen. Take, for instance, the batch of *Bilbergia rhodocyanea*, of which there were hundreds in 5-inch pots. Every plant was an illustration of good culture, and, as the gardener in charge remarked, "très bonne." They will come into flower during the present month. Where in England could a similar feature be found in a nursery? We are more accustomed to see them in botanic gardens than as nursery plants in such numbers as these.

Marantas, such as *M. Kerchoveana* and *M. Sanderiana*, the latter having handsome green leaves with rose-coloured stripes; *Hæmanthus* species and hybrids, *Clivias* in thousands, *Aralias*, *Rubus reflexus*, *Musa rubra* (exhibited at the Temple Show by M. Truffaut in 1901, and figured in *Gardeners' Chronicle* May 25, 1901, p. 335), an excellent specimen of *Anthurium acaule*, *Heliconia illustris*, fine plants of *Adiantum tenerum* Farleyense, *Ficus Parcelli*, large quantities of Palms, *Codiaeums* (*Crotons*), *Cordylines* (*Dracænas*), and *Caladiums*, were other interesting plants in the houses. The newest varieties of *Caladiums* included *President Schneider*, a variety with silvery-coloured leaves veined with rose colour and having a rose-coloured centre. This was named in compliment to Mr. George Schneider, who is President of the Society of French Horticulturists in London. Another new *Caladium* is named *Rotomagno*, the leaves being coloured with rose, green and white. We have mentioned the *Codiaeums* and *Cordylines*, and it would be next to impossible to describe the excellent specimens of these ornamental plants that were seen in M. Truffaut's collection. Skilful cultivation, assisted greatly by the clear sunshine and pure air of Versailles, produce such satisfactory results as are seldom attained. M. Truffaut's nursery, as we have said, is not a large one, but it is a common remark among Paris nurserymen that it is made to produce a very large quantity of first-rate plants. M. Georges Truffaut, a son of the proprietor, has studied the subject of chemical manures, and the results of his experiments have been put to practical use. On the occasion of the recent international show at Paris he was given the distinction of *Commandeur du Mérite Agricole* by the President of the Republic.

MESSRS. VILMORIN, ANDRIEUX ET CIE.

Visitors to the Paris International Show, and especially those who went from England, were greatly impressed by the magnificent collection of flowering annuals and of vegetables and salads contributed by the firm of Messrs. Vilmorin, Andrieux et Cie. In a report published in these pages at the time, an attempt was made to give the reader some idea of the comprehensiveness and quality of those exhibits, and of the pleasing and artistic manner in which the annuals were displayed, as it were, in ordinary flower-beds.

Subsequent to the show we took an opportunity that presented itself, and visited the well-appointed seed shop and offices of the firm in the *Quai de la Mégisserie*, and from there we were conducted by train to the trial grounds at *Verrières*, some miles out of the city. At such a season there is not so much to see in a seed nursery as there would be at the end of the summer, but we could not help admiring the efficient and painstaking methods adopted in every branch of the establishment, whilst the enormous area of land employed for the testing of seeds astonished us. We tramped over field after field, every one of which was clean from weeds and in excellent condition. Some crops were already planted, but the bulk had only recently commenced to grow. Amongst many flowering annuals there, we noticed *Silene pendula* variety *ruberrima*

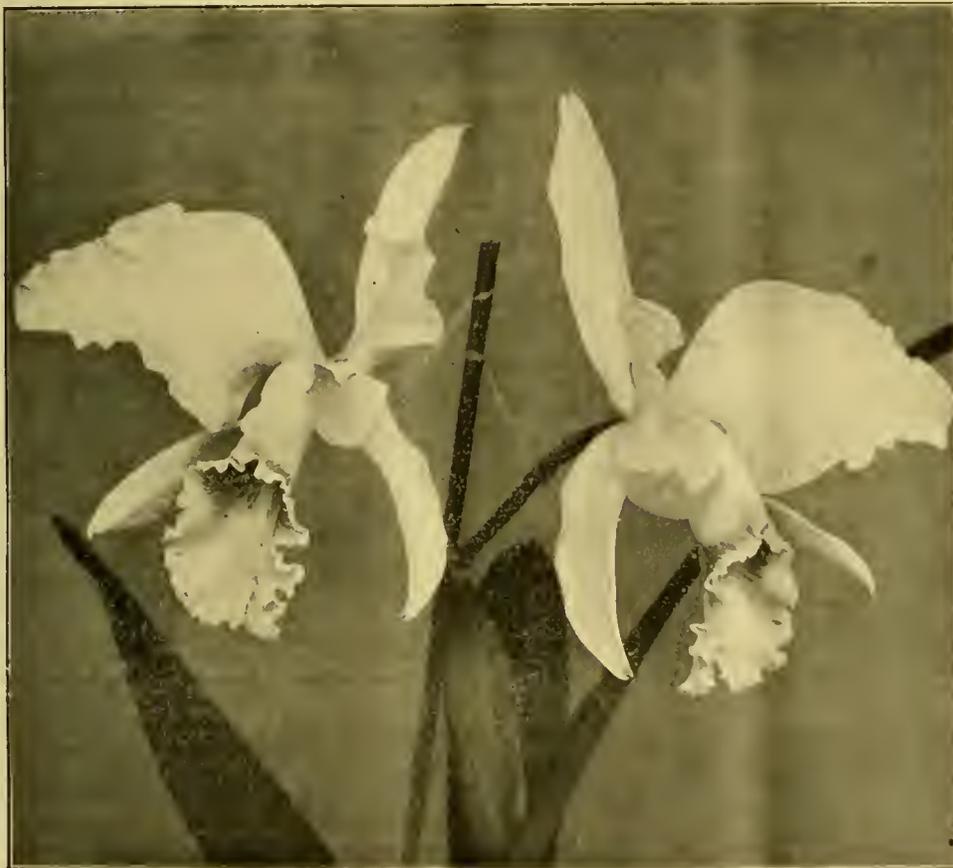

FIG. 5.—CATTLEYA MOSSIE "WHITE LADY."

A variety exhibited at the Temple Show by Messrs. Sander & Sons, St. Albans. Flowers white except the throat, which is pale lemon-yellow. The flower-segments, owing to the perspective, appear narrower than they are in reality. Photo by J. Gregory.

grace and elegance peculiarly their own and a beauty of form not surpassed if equalled by that of any other class of plants.

The present work then is sure of a welcome, for it is written by a specialist whose opportunities of studying Ferns and their ways have been unrivalled, and whose experience in their culture is second to that of no one else. After some preliminary notes the author deals with the methods of propagation, and then passes on to the cultivation of Ferns, either in the open or under glass. The directions are given in a clear, lucid, and concise manner, betokening the expert practitioner. The greater part of the book is occupied with an alphabetical list of genera and species, together with details as to their appearance and the best method of cultivating them. This list is very valuable, the more so that it is freely illustrated with characteristic wood cuts. We heartily commend it to the attention of all Fern-lovers.

six inches or so across. By the end of the season these will have made good plants, having flower-buds on every shoot, just as they are cultivated at Ghent and other places in Belgium. When the plants were removed from the frames these latter were planted again with rooted cuttings from the propagating-houses, and another batch of cuttings was put in to make roots. M. Truffaut's nursery is not an extensive one, but every yard of ground, indoors and out-of-doors, is pressed into use. Excluding the *Azaleas*, the remaining beds out-of-doors are utilised during summer for the cultivation of *Ficus elastica*. The beds are long and narrow, with a path on either side, and, like those containing the *Azaleas*, are composed of peat, the edging to the beds being of neatly-kept Box. To the English visitor these Box-edged beds have an unfamiliar appearance as part of a nursery garden, and remind him rather of an old English flower-garden. The

with double red flowers, and other varieties of *Silene* which had previously attracted our attention in the Parc Monceau and other gardens in Paris. This little annual might with advantage be grown in England for massing in beds more frequently than it is. It is significant that in Paris none of the English visitors appeared to recognise the plant until attracted close to the beds by the fine display of colour. In the glass-houses the principal displays were of herbaceous *Calceolarias*, *Gloxinias*, and *Primula obconica*. Of *P. obconica* there was a large quantity, and it was evident that every care is taken to cultivate as much variation in the colour of the flowers as it is possible to obtain. Some were nearly pure white, and others rich if not brilliant red, whilst in most cases the principal colours were grouped together and separated in batches.

A peep into the laboratory was sufficient to show us that the scientific principles underlying horticultural practice are studied, and that science is brought to bear upon the processes employed in the development of the strains of plants and in their propagation by seeds.

One of the most pleasant incidents of the visit was an inspection of the splendid rock-garden in M. de Vilmorin's private grounds adjoining the nursery, wherein also may be seen the famous hybrid *Abies* raised by the late Henry de Vilmorin between *A. Pinsapo* and *A. cephalonica* (see *Gardeners' Chronicle*, Feb. 9, 1901, p. 89, fig. 33).

The Week's Work.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Vines.—When the earliest crops of Grapes have been entirely removed, the Vines should be syringed daily, preferably late in the evening. Should red-spider be present, syringe the foliage with water containing soft-soap and sulphur, or some other suitable insecticide. Examine the borders, which have probably been allowed to become dry while the fruit has been finishing, and restore them to a moist condition. Should it be necessary, apply a light mulching to the border; this will prevent excessive evaporation. Waterings of clear water will generally be sufficient for young and vigorous Vines that are still freely making lateral growth, but older and weaker plants should be supplied with diluted liquid manure. Unless rain falls in sufficient quantity, outside borders should be watered copiously. Ventilate the house to the fullest extent. Houses which contain ripe Grapes should be kept in a cool and well ventilated condition, allowing a little artificial heat in the pipes during dull or wet weather in order to carry off excessive moisture. Black varieties such as Black Hamburg rapidly lose their colour after hanging for an appreciable time, and to prevent this a light shading should be applied. On the other hand, white varieties of Grapes not intended for present use are improved by being freely exposed to the sunlight, providing they are properly ripened.

Succession Vines.—Allow plenty of ventilation to houses in which the Grapes are approaching ripeness, only permitting artificial heat during the night time, or in damp or unsettled weather. Houses which contain the varieties *Madresfield Court* and *Foster's Seedling* should be carefully watered, and as soon as the berries begin to change colour, have the amount of atmospheric moisture gradually reduced, and the border covered with light litter. I do not advise withholding water altogether from the borders to obviate splitting in the fruits. The cracking frequently seen in the berries of these varieties is more often caused by too much atmospheric moisture, and by careless ventilation during unsettled weather, than by applying water to the borders. A little heat should always be allowed to radiate from the pipes; this, with careful attention to ventilation day and night, will allow a constant circulation of warm air to pass continually through the houses, when very little if any splitting of the berries will take place. Muscats which are now ripe or approaching to that stage should have some of the leaves drawn

aside from the bunches so that they may derive benefit from the light, but the berries must not be exposed to the full force of the sun.

Later Houses.—Continue to pinch the laterals and supply the necessary moisture by damping and syringing, taking care to close the houses early in the afternoon with the presence of sun-heat; but ventilation should be again applied about 7 P.M., and allowed to continue during the night. With liberal feeding and a more favourable period for growth these later Vines will mature a heavier crop than those which are forced earlier. Keep a sharp look-out for signs of scalding, especially on those varieties which are subject to this disfigurement. The house should be kept fairly warm at night-time and be freely ventilated throughout the day until the stoning period is passed. By allowing a little warmth in the pipes and a small amount of ventilation at night-time the berries of such varieties as *Lady Downes Seedling*, which are very liable to scalding, are kept dry and warm towards morning, especially in dull and wet weather, and thus the chances of injury from scalding are greatly lessened. Sudden rises and falls in the temperature of the house should be avoided by ventilating early and allowing the temperature to rise gradually. Thin freely those varieties intended for cutting and bottling during November and December.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Hippeastrums (Amaryllis).—Flowering bulbs that were started early in the year will by now have completed their growth, and should be gradually ripened off. Diminish the supply of water to the roots, but do not withhold water altogether until the foliage has withered. Full exposure of the plants to the sun is necessary for thorough ripening. Fumigate the plants on several occasions to destroy thrips, a pest to which they are very liable. Seedlings that have not bloomed would derive great benefit from an occasional watering with diluted sheep manure, but should be kept growing until they have flowered.

Nerine Fothergillii.—These should be examined occasionally, and any that show flower-spikes will require to have water afforded them.

Fine Foliage Plants.—Spring-propagated plants are making much headway. If it is intended to make specimen plants of any of them, they should at no time be allowed to become pot-bound. Maintain the atmosphere in a very humid condition, and keep a sharp look-out for insect pests, which must be checked at once. Use soft water only for syringing the plants and for applying to the roots. Hard water would soon disfigure the foliage with a deposit of lime that could only be removed by the use of a sponge. Afford those plants that are to be kept in small pots for table decoration, &c., frequent waterings at the root with weak sheep manure-water and about once a week apply a pinch of Clay's Fertiliser on the surface of the soil. *Allamandas*, *Clerodendron Balfourii*, *Dipladenia boliviensis* being very gross feeders should receive frequent waterings with diluted farmyard manure-water that the plants may make good strong growth. Examine *Ixoras*, *Dipladenia Brearleyana*, *D. amabilis*, and such-like tender plants, so very subject to attacks of mealy-bug, and remove this pest by the aid of methylated spirit applied by means of a camel's-hair brush. If this operation is performed with care no damage will be done to the tender growth by the use of pure spirit, but a soft camel's-hair brush only should be employed for the purpose.

Flowering Plants.—Continue to insert cuttings of *Poinsettias*, *Euphorbia Jacquiniflora*, *Moschosma riparium*, *Begonia Gloire de Lorraine*, *B. Haageana*, *B. Gloire de Sceaux*, &c., until a sufficient stock of each has been acquired. *Rhododendron (Azalea) indicum* may now with safety be placed out-of-doors in a good position to ripen their growth. The plants must not be allowed to become dry at the roots at any time. Those that have not been potted recently should be afforded an occasional dusting on the surface with Clay's Fertiliser. Syringe the foliage every morning and evening.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Epidendrums.—The genus contains very few plants having much horticultural value. Hybridisation, however, has been the means of producing a few forms of exceptional decorative merit, notably *E. × Boundii*. As a reliable show plant, *E. prismatocarpum* stands well in the front rank, being very floriferous, durable, and attractive. Were the flower-spikes allowed to remain uncut they would keep good for a couple of months; but for the sake of the plants they should be cut before the end of that period. When this has been done fresh surface material may be applied, or the plants may be repotted, as the case demands. When the latter is done, retain only three or four pseudo-bulbs to each piece, and make them up into suitably-sized specimens, filling the receptacles to half their depth with drainage material, and fixing the pieces in position with good lumpy peat and a small quantity of sphagnum-moss. A few leaves may be introduced, but as the plants have to be kept fairly dry during the winter months, it becomes less safe to moisten the compost again when required. Stage the plants with the *Cattleyas*, and treat them similarly, that is, afford a good supply of water when rooting, but at other times small and infrequent doses. *E. macrocheilum*, when it can be induced to thrive, is a showy kind; also *E. Watsonianum*, an allied species. These need rather small, well-drained pans, with peat and a little sphagnum-moss as a rooting medium. Suspend them in a light part of a *Cattleya*-house, and afford them very dry treatment, except just when rooting freely. *E. bicornutum* is a grand Orchid when seen at its best, but is generally very short-lived. Just now it is producing new growths, and ere these emit roots, fresh materials should be given. Plants of this grow best in baskets, with a few pieces of crock laid at the bottom, and the remainder filled with a mixture of equal parts of peat and sphagnum-moss. They may be suspended in an ordinary plant stove where there is an abundance of heat, light, and moisture, and where during the rooting period the plants may be frequently syringed. A close, stagnant, atmosphere will cause the young growths to damp off, and if during the resting season—which is a long one—they are not kept very dry, the pseudo-bulbs and roots become diseased. *E. vitellinum*, especially the autumn-flowering type, is a very showy, bright-flowering species with the additional merit of being a decidedly "cool" Orchid. Planted in small pots or pans, with ample drainage, and supplied with a small portion of peat and sphagnum-moss, this species should not fail to thrive grown along with the *Odontoglossums*. The lightest position in the house should be selected, and with care in watering, supplying much only when the plants are rooting freely, success should follow. Most *Epidendrums* having pseudo-bulbs need a long dry rest after growth has ceased, and even those with thin stems suffer less harm under moderately dry treatment than if kept saturated.

Miscellaneous.—At this season most Orchids, being in a more or less active state, need generous treatment. Let there be a buoyant atmosphere maintained by admitting abundance of air through the bottom ventilators whenever genial conditions prevail outside. Ventilation through the roof openings is seldom needed in the warmest houses, and in no case should it be employed when violent draughts would result. During exceedingly dry weather damp the ground immediately outside the houses, so that the air admitted will not be of a parched nature. Damping inside should be done sufficiently often to keep the air near to the saturation point, allowing drier conditions during mid-day. Fire-heat may not be required to maintain the temperatures sufficiently high, but a little warmth in the pipes is desirable at night in the warmest houses to promote a circulation of air and dispel superfluous moisture. The cool-houses should not need any fire-heat during this and the following month. Potting operations during this month should be confined to such plants as really need attention, especially in the cool-houses. Do not, however, omit attending to a plant when in a fit state for potting because it is not seasonable work.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN
Aston Rowant House, Oxon.

Raspberries.—The Canes for fruiting next season are now growing rapidly, but no more must be left than will be necessary or they will all fail to become as strong and well-matured as it is desirable they should be. Ply the Dutch-hoe frequently between the rows of plants, severing by such means any suckers that are not wanted. In order to conserve moisture in the soil a mulch of half-rotted manure or litter is better even than frequently hoeing the surface. Where the crop is likely to be heavy, apply frequent waterings of liquid-manure. In the case of Autumn-fruiting varieties it may be necessary to remove a few of the side growths at the thickest parts, so that plenty of light and air may freely circulate about the ripening fruits during the autumn months.

Gooseberries and Currants.—These have made considerable growth and in the case of cordons the lateral growths may be shortened and the points of the leading shoots stopped. Bushes may be treated likewise, shortening the side growths and pinching out the points of the main branches. This will have the result of increasing the size and colour of the berries. Aphis frequently congregate at this season on the points of the shoots, therefore all "stoppings" should be burned and the trees thoroughly cleansed afterwards by soapy water applied with the garden-engine. If this work is not done before the berries commence to colour, the Gooseberry fruits may be valueless for dessert purposes.

Strauberreries.—Where early runners are required for forming a new plantation to afford early supplies of fruit, these should be secured immediately they are ready, using large 60-sized pots for layering the runners in. Fill the pots with a rich compost, and secure the runners in position by placing a stone on them rather than by using a peg. Keep the soil in the pots in a uniformly moist condition by watering them twice daily through a rosed can. Pinch out the point of the runner just beyond the layered plant. As soon as the layers have become well rooted let them be immediately planted on a well-prepared border facing to the south, from which fruits may be gathered next season a week in advance of the usual crop. Forced plants that were planted-out some time ago should be kept free from runners. If the weather continues hot, mulching will be necessary, with waterings of liquid-manure. These plants will then provide a crop of medium-sized fruits later in the season.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C.
BENTINCK, M.P., Underley Hall, Westmoreland.

Tender Plants, such as Abutilons, Celosias, Humeas, Ricinus, may be placed in position.

Annuals.—Take advantage of dull, showery weather to thin these. By thinning early they escape the "weedy" and "short-lived" character sometimes given them.

Rockery.—Half-hardy plants of distinct habit may now be put on the rockery to add variety. Such are *Convolvulus mauritanicus*, *C. Cneorum*, *Crinum Powellii*, *Eucomis punctata*, *Opuntia Rafinesqui*, *Pratia begoniifolia*, and *Parachetis communis*.

Grey-foliaged Plants make a welcome contrast amongst the various colours in the mixed border. The following are a few of those most useful:—*Agave*, *Artemisia*, *Centaurea babylonica*, *Onopordon* "Robert Bruce," *Salvia argentea*, *Santolina incana*, *Senecio argentea*, *Teucrium fruticans*.

Violas.—Dry weather is adverse to Violas, but if generous treatment has previously been given the soil and ample waterings are afforded the plants, they will remain healthy until there is rain. Do not allow seed-pods to form. Stir the surface of the soil repeatedly.

Verbenas may be pegged down to cover the ground evenly. Destroy thrips and any other insect pest there may be present.

Roses.—Keep the plants free from pests. Afford thorough soakings with water, and hoe the surface of the soil frequently. Now that flower-buds are appearing liquid-manure may be applied, or a slight dressing of artificial manure. If

specimen blooms are required, disbudding must be given timely attention. Rub off all suckers as they appear. Frequently tie-in the growths of climbing Roses, especially growths near to the ground, as established plants of such varieties as *Gloire de Dijon* are apt to get "leggy." See that standard Rose-trees are made secure to the sticks.

Violets.—Afford copious waterings, and syringe the plants in the evening in dry weather. If red-spider is seen, apply a dressing of sulphur or Spidacide. Cut off runners as they appear, and keep a fine and loose surface to the soil of the beds.

Gladioli.—Apply stakes to these as soon as the flower-stems are seen. The plants may be staked singly, or if they are grown in rows put in a few sticks and stretch two or three strands of twine tightly across. Tie each flower to these strings with soft, broad material to avoid cutting the stems. A mulch of partly decayed manure would keep the soil moist, should the season be a dry one. Apply liquid-manure occasionally.

Primroses, Polyanthus, &c., may be sown, and seedlings of earlier sowings will be ready for thinning and pricking out into heavy soil in a shady position.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Carrots.—Sow seeds of some of the stump-rooted varieties of Carrots on ground that has been cleared of early Potatos. Work the ground well, and break it up as finely as possible before drawing the drills. They should be made 8 or 9 inches apart, choosing an hour in the morning for sowing such light seeds as those of Carrots. Every year we prove the usefulness of Carrots raised from seeds sown at about this time. If another sowing be made a fortnight or so later, in soil that is favourable to Carrots, the plants may be allowed to remain in the ground through the winter, and will then be very useful in spring. The variety Model I have found most suitable for this purpose.

Turnips.—In order to have Turnips in the best condition they should be pulled from the ground as they are required for use. It is therefore necessary that frequent sowings be made. The soil should be rich and moderately firm, as quality is best secured by rapid growth. Sow about the middle of July, and again in August and September. In the case of late sowings greater distance should be allowed between the lines, so that in the event of severe frosts the roots may be covered with soil, which is better than having to store the full supply. I have tried to bring the yellow-rooted varieties into favour, but up to the present have failed. Snowball is a variety of excellent quality and form, and from this we obtain our general supply.

Leeks.—Make a good plantation in drills drawn 18 inches apart, and afterwards afford water to the plants freely. Earlier-planted Leeks if intended for exhibition will now be making rapid progress, and should be freely supplied with liquid manure and soot. When brown-paper collars are used for the purpose of blanching, keep these collars gradually moved up until the desired length is secured, which may range from 15 to 18 inches, adding finely-sifted soil round the stem as growth advances. When the proper length is secured remove the collars. Fine soil is the most perfect blanching material for this purpose.

French Beans.—Seeds for producing a supply of this vegetable in autumn should be sown in sheltered positions, and where protection can be given. Veitch's Perfection and Canadian Wonder can be relied upon as suitable varieties. Earth-up and mulch advancing crops, and keep them well supplied with water.

THE APIARY.

By CHLORIS.

Bees and Clover.—People are accustomed to taking bees to the Heather, but few think of taking them to the Clover. The young bee-keeper hesitates to do either. He is afraid of the trouble of moving the stocks, to say nothing of the danger of a few stings. Most beemen who

have had no experience in the ways of these insects do not exercise enough care in the preparation, the consequence is that during the removal a few bees escape, fly about the amateur, settle on him, creep over his face, and by the time his destination is reached he has completely lost nerve. Nor do his troubles cease at this point, for when he reaches home his family discover that there are other bees on his hat, in his coat—in fact everywhere.

How to remove Bees.—All the combs in hives intended for removal should have the foundation wired in. The frames should be tightly wedged together, a piece of perforated zinc should take the place of the quilts, then two laths should be laid across the frames and screwed down, each with three or four screws. The entrances should be stopped with a piece of perforated zinc and the whole hive made thoroughly secure with a piece of rope. A great deal of preparation seems to be necessary, but the results will amply repay one. Place some straw in the bed of the cart or wagon, so that there shall be no unnecessary jar, and perform the task in the evening. Remember, no new combs, unless wired, should be in use. Neglect the warning and disaster is certain, and the colony thus situated meets with certain death.

Some Results obtained by removing Bees to Clover.

—A gentleman some years ago lived near a town, and was determined to get a good honey crop. During the second or third week in June he set off for a field of white Clover which was just coming into bloom (the season was wet, and he lived in the far north). He fed the bees well until the Clover came out in all its glory, and to his delight the weather became beautifully fine. He put on a crate of shallow frames containing drawn-out comb, and in six days it was almost full; underneath these he placed another crate of similar frames, and in a few days more these were full. The weather broke during the third week in July, but he had secured nearly 100 lb. of first-class honey, which fetched a good price, and won many first prizes at shows far and near. If I remember rightly, what with a good sale and the prizes, that hive's profit was equal to a ten pound note.

A HURRIED VISIT.—A French amateur, not unknown in the columns of the *Gardeners' Chronicle*, makes known in the columns of *Le Jardin* his impressions of London, as gathered in a stay of twenty-four hours. On landing at Dover he was not fortunate enough to secure a corridor carriage, and inveighs against our "sordides wagons," our "maussade," rain-dripping sky, the wretched workmen's dwellings, the hurly-burly at Victoria, and the narrow bed at the hotel. At 8 the next morning he paid a visit to Veitch's nursery, about which the writer indulges in compliment; then to the Temple Show at 10, where he found the tents old, narrow, and dark, but wherein the cultivation of the plants exhibited excited the admiration of our visitor. At 2 o'clock, a ride to Kew in a landau—entry by one gate, exit by another. House after house was inspected, and generally with satisfaction; but the Nepenthes-house was too hot. What the "*Aristolochia dioica macronia*" may be we can only guess, and our visitor cannot have had time to ascertain, for at half-past 6 he says he was in Richmond Park, noting the deer; then, passing again through the unlovely suburbs, he reached his hotel, snatched a hasty meal, left Charing Cross at 9 p.m. in the "horribles wagons" (again unfortunate) for Dover, passing the Crystal Palace and its fireworks as he proceeded. At Calais the bed in the sleeping-car was as wide as that of the London hotel. At 6 in the morning Paris was reached—Paris with its cheerful and bright appearance, its brilliant skies. "Oh, how beautiful Paris is!" he exclaims. "There is nothing like it in England"—and this after an experience of twenty-four hours. Well, perhaps he is right; still the next time he visits us we trust he will stay a little longer. There is really as much worth seeing in London as in Paris—only let him take a corridor train, and not come in November!

APPOINTMENTS FOR JULY.

SATURDAY, JULY 1	1	Windsor, Eton and District Horticultural Exhibition.
		Société Française d'Horticulture de Londres Meet.
MONDAY, JULY 3	3	Maidstone Rose Show.
		Royal Horticultural Society's Committees Meet.
TUESDAY, JULY 4	4	National Sweet Pea Society's Show at Royal Horticultural Hall, Vincent Square.
		Royal Scottish Arboricultural Society's Exhibition of Forestry and General Meeting at Glasgow (4 days).
WEDNESDAY, JULY 5	5	Croydon Horticultural Society's Show.
		Hanley Horticultural Fête (2 days).
THURSDAY, JULY 6	6	Tunbridge Wells Flower Show, Hereford and West of England Rose Show (2 days).
		Bristol and Bath Rose Show in aid of Royal Benevolent Institution.
TUESDAY, JULY 11	11	National Rose Society's Exhibition at Regent's Park.
		Flower Show at Belfast (2 days).
WEDNESDAY, JULY 12	12	Royal Horticultural Society's Summer Exhibition in the Grounds of the Royal Hospital, Chelsea (3 days).
		Harrow Flower Show.
THURSDAY, JULY 13	13	Wolverhampton Floral Fête (3 days).
		Cambridge Horticultural Show.
WEDNESDAY, JULY 14	14	Reigate Flower Show.
		Bath Rose and Begonia Show.
THURSDAY, JULY 15	15	Nottingham Horticultural and Botanical Society's Exhibition (2 days).
		Lee and District Flower Show (2 days).
SATURDAY, JULY 16	16	Beckenham Rose and Horticultural Show.
		Potters Bar and District Amateur Rose Society's Show.
TUESDAY, JULY 18	18	Clipping Norton and North Oxon Rose Show.
		Kidderminster and District Summer Flower Show.
WEDNESDAY, JULY 19	19	Royal Horticultural Society's Committees Meet, with National Carnation and Picotee Society's Show.
		National Rose Society's Show at Gloucester.
THURSDAY, JULY 20	20	Northumberland and District Flower Show at Newcastle (3 days).
		Horticultural Club (annual outing at Wisley).
WEDNESDAY, JULY 21	21	Cardiff and County Horticultural Society's Exhibition (2 days).
		Southern Counties Carnation Show at Southampton.
FRIDAY, JULY 22	22	Royal Botanic Society Meet.
		Handsworth Horticultural Show (2 days).

SALE FOR THE WEEK.

FRIDAY NEXT—
Odontoglossum Schröderianum, &c. by order of Messrs. Sauder & Sons. Imported Orchids in variety by order of Messrs. Stanley & Co. 80 Lots choice Hybrids. Odontoglossum crispum, &c., by Protheroe & Morris, at 12.30.
(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick— 43.1° .

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, June 28 (6 P.M.): Max. 75° ; Min. 58° .

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, June 29 (10 A.M.): Bar., 29.8; Temp., 66° . Weather—Dull.

PROVINCES.—Wednesday, June 28 (6 P.M.): Max. 70° , Guildford; Min. 45° , Barmouth.

The Vienna Congress.

THE main objects of the Congress held at Vienna from June 11 to 18, were two in number. In common with congresses in general it was a *réunion*: botanists from all parts of the world met together to renew old friendships or make new ones. On the first evening, when Professor JULIUS WIESNER, the well-known plant physiologist and head of the Vienna Plant Physiological Institute, welcomed the members at a very informal reception, 500 had already arrived, and the final list contained more than 600 names. Naturally, the Austro-German

element predominated, but practically all countries with a botanical interest were represented, from China in the East to California in the West, and quite a large number of Americans took part in the proceedings. We regretted to see so few Englishmen, but the middle of June is a busy time with our professional botanists, but, at any rate, those who were able to go were much in evidence. Among those present were Lt.-Col. PRAIRIE, Dr. REMBLE, Dr. and Mrs. SCOTT, Prof. MARSHALL WARD, S. WOODHEAD, and Dr. STAFF.

For many of the members the special object of the Congress was the conference on nomenclature which met to revise the Code of Laws promulgated at the Paris meeting by ALPHONSE DE CANDOLLE in 1867. It is to be hoped that the results of the conference will tend to solve the questions on which systematic botanists have been divided, and on which there has been so much discussion during the last ten years. For four or five hours on every afternoon during the week about 150 representatives, with Professor FLAHAULT, of Montpellier, as president, and the indefatigable Dr. BRIQUET as general secretary, met and worked steadily through the numerous amendments and modifications of the original laws. Dr. OTTO KUNTZE came for a few minutes only on one afternoon to protest against the Conference. He met with a hearty reception, but the proceedings showed that only a very small minority were in sympathy with his extreme views. The points at issue were freely discussed, but there was a marked absence of feeling and an evident desire to find a working solution of the difficulties.

From a horticultural point of view the chief result was the acceptance by a very large majority of votes of what Dr. KUNTZE has called the "*Codex inhonestans*." This is a long list of genera, the names of which are to be retained under any circumstances, though under the rule of priority they would be replaced by others less well known. These are names which have become established by long usage. Thus it will not be incumbent upon botanists or gardeners to replace *Cunninghamia* of ROBERT BROWN by *Belis* of SALISBURY, or *Sequoia* of ENDLICHER by *Steinhauera* of PRESL, though the second names are in both cases the earlier; and well-known names, such as *Leersia*, *Zoysia* and *Glyceria* need not give place to *Homalocenchrus*, *Osterdamia* and *Panicularia*, though the last three have the sanction of antiquity. In this respect a convenient, if arbitrary, result is reached.

The Conference also placed a ban upon the use of the too familiar "hort"—the flouting of new species without any, or with inadequate descriptions in horticultural publications. The members of the Conference perhaps did not recognise the fact that these names are given by nurserymen and dealers, and that as the plants are exhibited and pre-empted under these names, the "publications" are bound to adopt them, at least provisionally. If the abbreviation "hort." is affixed, the botanist knows that from his point of view the name has no significance. It is only a short time since we wasted a whole morning in the endeavour to verify a Latin name which had no other authority than that of the nurseryman who sent us the specimen. If the abbreviation "hort." or an English name had been given, or at least one not constructed according to botanical usage, we should not have been misled. The suggestion

that a new species must be accompanied by a description in Latin, English, French, German or Italian, called forth considerable discussion, especially on the part of the Scandinavian and Russian members, and the only possible solution seemed to be the insistence on a Latin diagnosis, which we may add it has been the practice of this Journal from the first to give. The law, however, is not to take effect before 1910, and will not necessarily apply to works part of which has already appeared. The members were also, though very unequally, divided on the question of the name to be used when a transference is made from one genus to another, or from varietal to specific rank. Ultimately a compromise was effected. In the former case the earliest "trivial" epithet persists, but not necessarily in the latter. Thus we shall say *Ipomoea Fes-caprae* (originally *Convolvulus Pes-caprae* Linn.), not *Ipomoea biloba*, though the latter binominal is the earliest under *Ipomoea*. On the other hand, if a var. major is considered, as a result of more careful examination or fuller knowledge, to be really of specific rank, the species need not bear the name major, which obviously might be quite inappropriate. With one dissentient, the Conference was unanimous against changing a name once given, however inappropriate; *Asclepias syriaca*, for instance, is quite unknown from Syria, but a name is a name and must stand.

The general programme of the Congress included a number of papers on various topics, such as the "Development of the Flora of Europe since Tertiary Times," a group of papers in one of which Professor WEBER referred to the Vine as occurring in the earliest known flora, an interesting fact from its general existence in Central Europe presumably only as an escape from cultivation at the present day. This topic also called forth the suggestion of the preservation of such plant formations as throw a light on the history of the flora. It was mentioned, for instance, that the characteristic primitive forests of Bosnia are in imminent danger of destruction, and the Congress was asked to help towards the conservation of a portion. An interesting account was given by Dr. SCOTT, of Kew, on the present position of our knowledge of the seed-bearing Fern-like fossils—the so-called Pteridosperms.

The first day of the Congress was the occasion of the opening of a botanical exhibition in the orangery of the ancient palace of Schönbrunn. The Schönbrunn gardens bring to our mind JACQUIN and the magnificent folios associated with his name, and one of the features of the exhibition was a display of some of his original drawings and MSS.; and an item of the general programme was the unveiling of a bust of NICOLAS JOSEPH JACQUIN in the Festal Hall of the University. In his appreciative oration Professor WIESNER referred to the important position which JACQUIN held in the general scientific, and especially the natural scientific world in the second half of the eighteenth century. At the same time a similar honour was paid to a contemporary of JACQUIN'S, JAN INGEN-HOUSZ, a court physician, but known to botanists as one of the earliest workers on plant physiology, especially nutrition—" *qua ratione plantæ aluntur primus conspexit*."

An interesting feature of the botanical exhibition was the unique specimen of a

CRINUM RATTRAYI, A SPECIES FROM THE LAKE ALBERT DISTRICT IN UGANDA; FLOWERS WHITE; OF REAL SIZE; OUTLINE SHOWING HABIT.

curious Asclepiadaceous plant, *Fockea capensis*, brought originally from the Cape, but not found since. It develops annual shoots from a hard persistent woody rhizome as large as a child's head.

At the final meeting of the Congress, in response to an invitation from the Belgian members, voiced by Professor ERRERA and supported by the Belgian Government, Brussels was selected as the meeting place for the third International Congress, which will meet in 1910.

CRINUM RATTRAYII.—Our Supplementary Illustration shows a beautiful, pure white, fragrant *Crinum*, for which Sir TREVOR LAWRENCE, Bart., received a First-class Certificate at the Royal Horticultural Society, March 28 last. The plant was introduced by Major RATTRAY, then of the King's African Rifles, at Entebbe, and now of Rattray's Sikhs, in the Punjab, India. Major RATTRAY sent the first bulbs from his garden at Entebbe, and has kindly forwarded a photograph of one of the plants growing there. The plant is not indigenous in the Victoria Nyanza district, the specimens at Entebbe being cultivated ones. Later, Major RATTRAY sent to the neighbourhood of Lake Albert, where it is said to be indigenous, and secured the bulbs which are now in cultivation. Horticulturally this is one of the finest and most distinct of *Crinums*, the large pure white flowers and ascending dark green leaves rendering it easily distinguishable. Botanically it appears to be the most ornate of the *C. giganteum* section. We may remark that even in its own country it commanded admiration, for Major RATTRAY reports that the natives assert that when MUSA was King of Uganda, this *Crinum* was dedicated to his use and that of the highest chiefs, and heavy penalties were inflicted on others found in possession of the plant.

ROYAL HORTICULTURAL SOCIETY.—EXAMINATION IN COTTAGE AND ALLOTMENT GARDENING. —After a careful perusal of the 139 papers returned from the various centres, the examiners report a distinct advance in the answers pertaining to the practical treatment of cottage and allotment gardens in general as compared with those of the previous examination in 1904. A goodly number of those in the first-class, notably such as form the upper half of it, have evidently gained considerable experience in the working of such gardens themselves, whilst some of the answers given afforded peculiar pleasure to the examiners. The answers given to question 1 showed in several instances that the method of trenching was clearly understood. Several candidates greatly confused the terms "pyramids," "bushes," "cordons," and "espaliers," as applied to fruit-trees. The term "herbaceous" as applied to flowering plants also showed a deficient knowledge, whilst, singular to say, only a very small number included *Roses* amongst woody plants suitable for cutting and bunching for sale or otherwise. "Annuals," "biennials," and "perennials" were also much confused with each other. In the making up of hot-beds the replies were frequently vague and lacking in detail. Guesswork characterised some replies—notably in advising that "early Peas should be raised from roots saved over from the previous year," that "Raspberries should be propagated from cuttings," and that "Apples in some cases should be raised from seed." The results of these examinations show on the whole that it is quite possible for the children in elementary schools to be well instructed in cottage and allotment gardening, and the knowledge thereby imparted will, without doubt, bear good fruit in years to come. The examiners were ALEXANDER DEAN, V.M.H., and JAMES HUDSON, V.M.H.

— EXAMINATION IN HORTICULTURE. — The annual examination in the principles and practice of horticulture was held on April 12, 1905, when 160 papers were sent in; 300 marks were allotted as a maximum, all candidates who obtained 250 marks and upwards being placed in the First Class. The total number of these was 20, or 12.5 per cent. of the whole. Those who secured 200 marks and fewer than 250 were placed in the Second Class. The number was 67, or nearly 42 per cent. Those who obtained 100 marks and upwards were placed in the Third Class, the number being 71, or nearly 44.4 per cent. Three only were not placed. There has been a continuous decrease in the number of candidates since the Council adopted a more advanced syllabus, as there were 229 in 1902; 198 in 1903; 190 in 1904; and 160 in 1905. Comparing the percentages of the number in each class with those of 1904, they were: last year, First Class, about 18.3; Second Class, about 49.2; Third Class, about 32.4; so that the greatest reduction is in the First Class, or about one-third. With regard to the Elementary Principles, the syllabus now requires a higher standard of knowledge; but many of the papers of the First Class were

FIG. 6.—CRINUM RATTRAYII FLOWERING IN MAJOR RATTRAY'S LATE GARDEN AT ENTEBBE.

quite equal to it, especially perhaps in matters which are presumably learnt from books. Comparatively few of the 160 attempted to give the morphological characters of the two natural orders required. We infer that this elementary branch of botany does not meet with the encouragement it deserves. In Practical Horticulture, the candidates confined their answers more strictly to the letter of the questions than they have done on previous occasions, and the knowledge imparted by the various lecturers throughout the country has evidently not been in vain. The examiners were Prof. GEORGE HENSLAW, M.A., V.M.H., and JAMES DOUGLAS, V.M.H.

THE NATIONAL ROSE SHOW.—We would remind our readers that the twenty-ninth Metropolitan Show of the National Rose Society will be held in the Royal Botanic Gardens, Regent's Park, on Thursday next, July 6. It will be remembered that the Society's shows were held for many years at the Crystal Palace, and subsequently for several seasons in the grounds of the Inner Temple, Thames Embankment. This year a fresh place has been chosen, owing to the Temple Gardens being no longer available, and it will be interesting to watch the result of the innovation. The value of the money prizes, pieces of plate, medals, &c., to be awarded is £270. The three Champion Challenge Trophies will also be again competed for.

THE FRUIT CROPS IN KENT.—The sales of Cherries on the trees that have been recently held in the Maidstone district show how variable is the amount of the crop; thus, on one farm 4 acres of Cherries yielded £48, whilst the crop from 3 acres not many miles away, brought only £2. The highest price, according to a Kentish paper, was yielded by a crop from 13 acres. The bidding began at £200 and ran up to £460! From exactly the same area elsewhere only £72 was realised. Near Sittingbourne, 11 acres of Cherries fetched £250. "Both from a grower's as well as from a buyer's point of view, the sales as a whole are stated to have been the most depressing experienced for some years."

HORTICULTURAL CLUB.—The summer excursion is fixed for Thursday, July 20, and it has been decided to carry out the following programme:—Saloon carriages will be attached to the train leaving Waterloo Station at 10.5 for Weybridge, where brakes will be in readiness to convey the party to the new Garden of the Royal Horticultural Society, Wisley. After luncheon at the Hut Hotel, brakes will convey the party to Chertsey, where a launch will be waiting to convey the members and their friends to Kingston-on-Thames, tea being served on board. Kingston will be reached about 5.30, and Mr. JAMES WALKER has kindly invited the party to visit his garden on Ham Common. Brakes will be in readiness at Kingston to convey the party to Mr. WALKER'S, and later either to Richmond or to Kingston railway stations.

PRODIGIOUS STRAWBERRIES!—Messrs. LAXTON BROTHERS, of Bedford, called at this office on Tuesday last to show us some of the earliest fruits of the new variety Bedford Champion, which we remember to have seen last season in the Bedford nurseries. The large size of these early fruits may be imagined when we state that six of them weighed 1 lb., and twenty-five fruits weighed 4½ lb. The variety is one obtained from crossing a seedling from Noble and Sir Joseph Paxton with another seedling from Scarlet Queen and John Ruskin. Besides being of such large size, the fruits develop very high colour, and a flavour similar to those of Royal Sovereign; and the seeds being nearly buried in the flesh, the fruits are smooth to the palate. It should be added that the fruits mentioned were "king" fruits—a technical term for fruits produced by the central flower in a truss, which, as gardeners and botanists know well, are always bigger than the rest.

A CONIFER DISEASE.—The June number of the *Journal of the Board of Agriculture* mentions that a batch of diseased Spruce seedlings was recently sent to the Royal Botanic Gardens, Kew, from upland Yorkshire, accompanied by a statement that the disease was most prevalent at the crowded end of the seed-bed; the portion where the plants were not so crowded appeared to be fairly free from it. Examination showed the disease to be caused by a fungus called *Herpotrichia nigra* by Hartig, who recorded it as an injurious parasite in the Spruce woods of the Bavarian forests. The leaves are attacked and killed by the fungus, but instead of falling when dead they are bound together by mycelium or spawn, and remain as a compact brown mass clustered round the branch from which they sprang. These dense clusters of dead leaves, fixed to the branches by dark-coloured, cobweb-like mycelium, are very characteristic. The fruit of the fungus and also minute lumps or "sclerotia" are produced on the leaves. The parasite is most prevalent in nurseries at high elevations, and has been recorded as attacking Spruce (*Picea excelsa*), Mountain Pine (*Pinus montana*), and Juniper (*Juniperus communis*). It occurs in Germany and Norway; it does not appear to have been previously recorded

in Great Britain. The following observations with a view to its prevention are made in HARTIG & SOMERVILLE'S *Text-Book of Diseases of Trees*:—"It is an interesting biological point that the fungus grows especially when the temperature is low, under the snow or during the time it is melting, because in such circumstances the air is completely saturated with moisture. The frequency of the disease at high elevations has led to the general adoption of the practice of forming Spruce nurseries at low altitudes. It has also been found a good plan to look over the nurseries immediately after the melting of the snow, and to raise up all prostrated plants in order that they may be exposed to the wind. It would also be a step in the right direction in planting out trees to set them on hillocks and similar elevations, and to avoid placing them in hollows and other depressions." It is important that diseased seedlings should be collected and destroyed by burning, otherwise the numerous fruits and sclerotia present on the leaves would prove a source of danger in the future.

EFFECTS OF RINGING.—In the *Comptes Rendus* for June 5, we note a paper by M. LECLERC DU SABLON, on the effects of "ringing" or annular decortication on the distribution of hydro-carbonaceous reserves (starch, &c.), in the stems, roots, and leaves of trees. The experimenter concludes that the leaves contained more reserve substances in the decorticated than in the uninjured trees. The products of assimilation, unable to reach the roots, accumulate in the leaves and stems. Thus is explained the considerable increase in the crop obtained by ringing fruit-trees. Chlorophyll is less abundant in the leaves of decorticated trees, the leaves being usually noticeable for their yellowish colour. There seems to be a sort of regulation of the assimilating function; the chlorophyll products of assimilation have no longer their normal outlet, and encumber the leaves, causing a diminution in the production of chlorophyll. The experiments, in fact, clearly demonstrate the interchange of reserve substances that takes place between the stem and the root—an interchange discovered previously by direct study of the distribution of the same substances in a tree not decorticated. At the end of winter and at the beginning of spring the reserves move upwards from the root towards the stem, thus causing in the liber an ascending current of elaborated sap. From May to October the movement is in the reverse direction from the stem to the root. Comparative analyses show further the quantitative importance of these interchanges.

NARCISSUS WITH FOUR BLOOMS ON A SPIKE.

—A correspondent sends us an illustration in the *People's Journal* of a double form of Narcissus, which, growing in a market garden near Dundee, has developed four perfect flowers on a single spike. Many instances of two flowers on a single spike have come under our notice, but cases in which there are four are less common.

SALE OF GARDEN ORNAMENTS.—Messrs. ROBINSON & FISHER'S sales during last week included some valuable garden ornaments, of which the more important were as follows:—A pair of large, old, carved stone vases in subjects "Fire" and "Water," and covers, surmounted by figures holding globes, with the pedestals—£51 (VAN STRAATEN); a pair of old lead statues of a youth and girl dancing, 5½ feet high, with the carved stone pedestals—54 guineas (FEETNAM); a pair of lead figures of a shepherd and shepherdess—£160 (VAN STRAATEN); six fine old Vincenza figures, 56 inches high—75 guineas; a square sundial, standing 7½ feet high on finely-carved stone-shaped pillar with sunk panels of Acanthus leaf, &c., and surmounted by an old lead figure of "The Eird Catcher"—41 guineas (BROWN); a

pair of wrought-iron gates of Renaissance design, Italian, sixteenth century, 10 feet by 6 feet 6 inches—63 guineas; a set of four statuary marble figures representing Europe, Asia, Africa, and America, each 63 inches high—91 guineas (FERGUSON); and a fine old English wrought-iron park gate in three sections, the centre one opening 4 feet 3 inches, the panels at either side 4 feet each, the whole decorated in fine scrolls, pateræ, &c., height 10½ feet, removed in 1745 from Sir ROBERT DASHWOOD'S house, Northbrook, Oxon—94 guineas.

THE REPORT OF THE DEPARTMENTAL COMMITTEE ON FRUIT CULTURE just presented to Parliament records the opinion that this industry is the only form of agriculture which shows any progress. The following, says the *Daily Chronicle*, are among the most important recommendations of the Committee:—

A special sub-department of the Board of Agriculture and Fisheries should be established to deal with matters connected with the fruit industry. The suggestion is that there should be two branches of such a sub-department: (a) a bureau of information; (b) an experimental fruit farm.

Horticulture should be taught in elementary schools in country districts, and such schools should have school gardens attached wherever possible.

A large fruit farm should be established in proximity to the experimental farm, where fruit-growers and lecturers could receive a practical training.

Compensation should be paid on rules laid down by experts to an outgoing tenant of a holding under the Agricultural Holdings Acts on the basis of the value to the incoming tenant.

A Bill should be passed in Parliament for facilitating the purchase of small holdings by tenants with assistance from public funds.

The State should be empowered to lend money to landowners who have fruit on their estates, for the purpose of supplying the ready-money required for the payment of compensation at the determination of a tenancy.

A more simple and uniform system of rates for fruit should be introduced by the railway companies.

Building bye-laws in country districts should be modified so as to allow of the cheaper construction of cottages.

"FRUIT PRESERVING."—A pamphlet with this title, written by Mr. J. H. COOK, and published by the "Pitman" Health Food Co., Birmingham, appears appropriately at this season of the year. It includes not merely directions for preserving fruit, but a strong plea for a diet consisting of cooked fruits eaten with nut-meal and brown bread and butter. Not stopping to analyse the statement that "what sunlight applied outwardly is to the pores of the skin in its purifying effects, so are fruit-juices to the inside coatings of the body, having in this respects effects exactly opposite to those of meat-juices," we may say that the recipes for storing a wealth of fruits until a season of dearth will be found useful.

ARCHAIC BOTANY.—Dr. PENZIG, of Genoa, has recently published an account of two herbaria formed in the sixteenth century (1529—1532) by GHERARDO CIBO, and preserved at Rome. These herbaria date from some thirty years before that of CÆSALPINUS, nineteen years before that of ALDROVANDUS, and eight years before those of the two English botanists, TURNER and FALCONER. Dr. PENZIG gives an enumeration of the plants in these herbaria. Among them are specimens of Cotton, of Maize, of *Opuntia vulgaris*, and Sugar-cane, which are interesting in view of the then recent discovery of the American continent. In all some 1440 different species are preserved in these herbaria, among them being many cultivated in ornamental gardens or for utilitarian purposes. An index of vernacular and scientific names adds greatly to the value of this interesting publication.* In the same work Professor PENZIG has a note on a codex of *Materia Medica* of Dioscorides preserved in Rome. The writer alludes to the famous copies in Vienna and Oxford, but, so far

* *Contribuzioni della Storia della Botanica*, Milan, Ulrico Hoepli, 1905.

as we have seen, does not allude to the Rinuccini manuscript, which was sold in London for £590 in 1857. Some reference was made of this in the *Phytologist* for December, 1857, where also copies of the figures of Papyrus, Nelumbium, and *Nymphaea Lotus* were given.

CARPET-BEDDING AT MAIDENHEAD.—There is always a great deal of summer bedding to be seen along the Thames banks in the boating season. In one garden between Maidenhead and Bray, the Japanese flag may be seen carried out in dwarf plants of suitable colours, and on the same lawn is the name "Togo" in large letters-worked out with little plants as a tribute to the popular Japanese Admiral. Among the less formal arrangements the arches and pillars covered with Rambler and other Roses, and the white Pinks, are very effective in the river-side gardens just now. The decoration of the house-boats is, as usual, satisfactory in proportion to the simplicity of the schemes adopted; flowers of one or at most two colours, and of course plenty of foliage, being more admirable than the confusions of red, pink, blue, and yellow occasionally displayed.

"SUMMER HOLIDAYS."—From the publishers, at 30, Fleet Street, E.C., we have received a pamphlet entitled *Summer Holidays*, by PERCY LINDLEY. The publication is issued under the auspices of the Great Eastern Railway Company, and includes tempting accounts of spots in East Anglia and other districts traversed by the line. There are some capital pen-and-ink illustrations, and the coloured facsimiles of water-colour paintings are charming. The booklet is brought up to date, and should prove useful to many intending travellers.

COVENT GARDEN FLOWER MARKET.—We hear so much of the necessity for "waking up," that it comes as an agreeable variation to be told that in some matters we excel. That "mud-salad" market should be picked out as an example of our superiority is still more surprising. Nevertheless, the *Florists' Exchange* contrasts the arrangements of our flower market with that in New York, and shows that the advantage is this time on our side of the Atlantic.

"JOURNAL OF ECONOMIC BIOLOGY."—We hear that it is proposed to issue in September the first part of the *Journal of Economic Biology*. This periodical is to be edited by Mr. WALTER E. COLLINGE, with the co-operation of Professors A. H. R. BULLER, of Manitoba; GEO. H. CARPENTER, of Dublin, and Messrs. ROBERT NEWSTEAD and A. E. SHIPLEY, F.R.S. The Journal is planned to meet the need for a recognised medium for the publication of original investigations in economic biology. The result of researches will, it is hoped, be reported promptly, and a special feature will be made of the necessary illustrations. A number of British and foreign biologists have promised their support, and it is hoped that the Journal will be found in all university, scientific and public libraries, as well as in the private libraries of scientists. Communications should be addressed to the Editor. The publishers are Messrs. DULAU & Co., 37, Soho Square, W.

PRESENTATION TO MR. FORREST, HADDO HOUSE GARDENS.—On Thursday, June 22, a large number of the leading inhabitants in the district, and the *employés*, with their wives and families, on his Aberdeen estate, were invited by the Earl and Countess of ABERDEEN to join with them in honouring their head gardener at Haddo House, Mr. J. FORREST, who is retiring from active duties after a service of forty years. A very large number accepted the invitation. The chief feature of the meeting was the presentation to Mr. FORREST of many handsome and valuable

presents from the Aberdeen family. Lord ABERDEEN spoke in terms of cordial appreciation regarding the manner in which Mr. FORREST had devoted himself to the duties of his position, and referred to his desirable personality and influence in the district. The feelings of esteem with which he was regarded had already been betokened in a practical manner, one of these expressions being in the shape of a handsome gold watch, offered by the staff at Haddo House and on the estate, and by some other friends and acquaintances. The gifts from Lord and Lady ABERDEEN consisted of a gold watch-chain, gold pencil-case, and gold locket. Lady ABERDEEN presented Miss FORREST with a magnificent brooch in the form of a cairngorm and amethyst beetle.

A CRICKET MATCH.—On Thursday, June 22, the annual match arranged between the firms of Messrs. PROTHEROE & MORRIS, Cheapside London, and Messrs. SANDER & SONS, St. Albans, took place amidst the pleasant surroundings of the Clarence Park enclosure at St. Albans. A well-contested game, the result of which was in doubt until the last few minutes of play, ended in a long-hoped-for victory for the St. Albans players by the narrow margin of twenty runs. Previous to and after the match, the players and other employes, with several of the members of the two firms, were entertained to lunch and tea in the large hall at the residence of Mr. SANDER, when opportunity was taken to express the pleasure occasioned by these annual gatherings.

SPRAYING WEEDS.—The beneficial effect of spraying with copper sulphate in solution in the case of Charlock has led to enquiries being made as to its use in the case of other weeds. In the Report of the Ontario Agricultural College, 1905, we find that experiments were made by Mr. JARVIS, the lecturer in biology, on the effect of the spray on nearly thirty different kinds of weeds, but that practically spraying was effectual only in the case of Charlock. The strength of the spray was 9 lb. of copper sulphate to 45 gallons of water.

EUCALYPTUS.—The following are the species recorded as cultivated in the open-air in British gardens:—

coccifera	alpina
cordata	amygdalina
Globulus	resinifera
Gunnii	coriacea
leucocylon	polyanthema
urnigera	Staigeriana
viminalis	submultiplineris =
vernica	pauciflora
calophylla	stellulata

For the hybrids see *Revue Horticole*, 1903, p. 325. See also *Gardeners' Chronicle*, May 7, 1881; February 2, 1884; November 26, 1886; June 30, 1888.

MEMORIAL OF THE LATE P. B. WEBB.—Under the title "Webbia," we note the publication, in Florence, of *Raccolta di Scritti Botanici pubblicati in occasione del 50th Anniversario della Morte di Filippo Barker Webb*. The souvenir includes a brief account of the life and travels of the botanist, with some of his last letters to Dr. MONTAGNE, which are of great interest, though the proofs of those which were written in English should have been revised by an English botanist. Mr. WEBB's benefactions to Florence are handsomely acknowledged, and some 300 pages of the memoir are devoted to various botanical subjects, including one by Signor BECCARI on the Palms of the genus *Trachycarpus*. The editor of "Webbia" is Professor MARTELLI, of Pisa.

THE CONIFERS OF FORMOSA.—In the number of the *Tokyo Botanical Magazine*, dated April 20, 1905, is an article by Mr. B. Hayata on the "Conifers of the Island of Formosa and their Distribution." Seventeen species are enumerated, all Japanese or Chinese or both, except one that is peculiar to the island and which is not

known to us, viz., *Chamaecyparis formosensis* of Matsumura. The greatest affinity seems to be with the Japanese flora, which indicates a former land connection between Japan and Formosa—a connection traces of which are met with in the Liukiu islands.

GUIDE BOOKS RECEIVED.—The approach of the travelling season is marked by the issue of various books useful to the intending tourist. We note *Horsham and St. Leonards Forest*, in the well-known series of "Homeland Handbooks," published from 22, Bride Lane, Fleet Street. The volume is written by the Rev. W. A. Goodlife, and contains a chapter upon Christ's Hospital, an Ordnance map, and plenty of pictures illustrative of a beautiful neighbourhood. *Rhineland* is an illustrated booklet by Mr. Percy Lindley, and mentions some of the less familiar side-valleys of the Rhine to be reached by the Great Eastern Railway Company's routes *via* Harwich and the Hook of Holland. It is published at 30, Fleet Street. *Tours in Galloway* is issued under the auspices of the Portpatrick and Wigtonshire Joint Railways, and is a pleasantly written and abundantly illustrated guide to a beautiful neighbourhood. It includes a list of hotels and lodging-houses in the district.

PUBLICATIONS RECEIVED.—The *Journal of the Board of Agriculture*, June. Principal contents: Hedgerow Timber, A. C. Forbes; Experiments in the Improvement of Wheat; Manuring of Forest Trees.—*The Agricultural Gazette of New South Wales*, May. Among the contents are: Phytophthora infestans (Potato disease) in New Zealand, C. T. Musson; Potatoes prohibited from New Zealand; Useful Australian Plants and Notes on Amsinckias, J. H. Maiden; Wheat-growing in New South Wales, and Paspalum dilatatum, W. S. Campbell; Royal Botanic Gardens, Ceylon.—*Administration Reports, 1904*, part iv. Education, Science, and Art, by Dr. J. C. Willis, Director. Much extra work was done in the opening of an Experimental Station and the formation of an Agricultural Society, and this and other progress is of much service to planters and others. Much more space is required for the Museum and Library, and it is hoped that this will soon be gained.—University of California: College of Agricultural Experiment Station: *Asparagus and Asparagus Rust in California*, by R. E. Smith.—From the United States Department of Agriculture we have received the following: Bureau of Plant Industry, Bulletin No. 68—*North American Species of Agrostis* by A. S. Hitchcock; Bulletin No. 72, Part iii.—*Extermination of Johnson Grass* (with no indication of the name of the species), by W. J. Spillman; Bulletin No. 72, Part iv.—*Inoculation of Soil with Nitrogen-Fixing Bacteria*, by A. F. Woods.—*Farmer's Bulletin No. 248—The School Garden*, by L. C. Corbett; No. 249.—*Tomatoes*, by L. C. Corbett.—University of Illinois, Agricultural Experiment Station, Bulletin No. 98—*The Carrot and the Apple*, by C. S. Crandall, and No. 100—*Directions for the Breeding of Corn, including Methods for the Prevention of In-Breeding*, by C. G. Hopkins, L. H. Smith, and E. M. East.—*Trees*, vol. iii., by H. Marshall Ward (Cambridge University Press).

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

FLOWER-SHOW TENTS.—The complaint made as to the great heat generated in the long tents at the Temple Flower Show is no new one. There the heat is intensified by the great length of certain of the tents, their lowness and the crowds of people who throng them making the heat and close, stifling atmosphere almost unbearable. But excepting the crowds, the complaint is equally made at all shows under canvas in hot weather, and because of the structure of the canvas little seems possible on the part of the respective executives to remedy the evil other than by having the side canvases well unlooped. When that is done it is too often only after the heat in the tents has become excessive, and cut flowers especially have greatly suffered. There can be no doubt, because tent-roofs are so stupidly constructed, that top ventilation of an efficient kind is practically impossible, that the next best remedy is found in unlooping the sides of the tents. But that cannot be always done, as whilst the internal temperature in a close tent may be high, there may be outside a strong wind blowing, which may be objectionable to plants or other exhibits. Until tent roofs are made to have in them large gores or sutures that can be uncovered by drawing back canvas flaps, or be re-covered if rain comes, there seems no hope of getting top ventilation in tents. Show managers would do well to have thermometers in tents, and as soon as the temperature rose to 70° have the sides unlooped down on the leeward side, and all round if the atmosphere was quiescent. Owing to the staging arrangements in the long tents at the Temple, the sides being banks of flowers, even with looping down not much air would be admitted. That difficulty would be best overcome by having broader centre stages and abolishing the side ones. A. D.

RICHARDIA ELLIOTTIANA.—Although the production of double spathes in *Richardia africana* is quite a common event, I am unaware of any record of the occurrence of this phenomenon in *R. Elliottiana*, unless the specimen shown by Mr. Charrington before the Royal Horticultural Society's Scientific Committee on April 25 (see *Gardeners' Chronicle*, p. 286) may be taken as an example. The enclosed photograph shows two plants of this species which flowered in April last, one plant bearing two leaves and a normal spathe, while the other plant possesses but one leaf, the other having evidently become specially modified or developed into a large outer spathe enclosing a smaller or normal spathe surrounding the spadix. The outer spathe measured 9½ inches in length and 6½ inches in diameter, and is entirely coloured yellow. The inner spathe is 5 inches in length and 4½ inches in width. *Ernest G. Creek, Westerfield House Gardens, Ipswich.* [We have seen several similar specimens. ED.]

POLYGONUM BALDSCHUANICUM.—There is a very fine plant of this ornamental climbing Polygonum in the garden of Colonel Maxwell Withan, at Kirkconnel, Newabbey, Scotland. It has been there for four years, and it is quite apparent that the soil and situation suit it admirably. Planted in a border, it has completely covered two old Apple-trees, retained for covering with climbers, and it rambles freely over these, veiling the gnarled branches with its fresh green leaves, and in summer decorated with a wealth of the small white and blush flowers it yields in such profusion. The soil at Kirkconnel is of a peaty nature, and here the Polygonum is quite at home. The climate is mild, though as the situation is low and near the river Nith, spring frosts are sometimes troublesome. P. Baldschuanicum receives no special treatment here, however, and proves a success year by year. *S. Arnoll, Sunny-mead, Dumfries.*

PROVINCIAL FLOWER SHOWS SIXTY YEARS AGO.—I have been considerably interested in perusing the "Fourteenth Annual Report of the Royal Devon and Cornwall Horticultural Society" for the year 1844, kindly lent me by a friend resident in the neighbourhood of Plymouth. From this it appears that the Society was formed in 1830, and that it held three shows annually at Plymouth. From inquiries that I have made I understand that this Society continued its work for a period of about twenty-five years, when it passed out of existence. Between that date and the establishment of the present highly-successful Chrysanthemum Society a few years ago, several attempts were made to inaugurate a series of similar shows; but these attempts were always attended by failure. The only flower-shows now held at Plymouth are those of the Chrysanthemum Society alluded to, early in November, and of the newly-formed Devon Daffodil Society, which held its first exhibition in April, 1904. On referring to the Report I find that, in the year 1844, the Society was possessed of invested capital to the amount of rather over £400, and that its yearly revenue from all sources was about £250. The name of His Majesty the King, then Prince of Wales, appears as Grand Patron of the Society, and in the lists of patrons, presidents, vice-presidents, and subscribers are to be found the names of most of the notabilities in Devon and Cornwall. That the giving of prizes to exhibits of poor quality was strictly discountenanced sixty years ago is proved by Regulation 2, which directs that "no prize shall be awarded where the article exhibited has not been considered by the judges to possess a large share of positive merit," and that there shall be no lack of critical judgment in deciding on the merits of exhibits is provided for by Regulation 16: "The judges shall be at least twelve in number—viz., three for fruits, three for flowers, three for vegetables, and three for cottagers' prizes." With regard to cottagers, it is universally held that, in comparison with bygone years, the labourers' lot to-day is vastly improved. That this contention holds good in the case of wages is borne out by Regulation 1 for Cottagers' Classes, which reads, "Cottagers shall consist solely and exclusively of agricultural labourers whose wages do not exceed 12s. a week." In the matter of flower-shows, however, although I do not profess to have a

knowledge of their conditions in various parts of the country, I imagine that few in the present day would be found where cottagers were more liberally provided for than in the exhibitions held under the auspices of the Devon and Cornwall Horticultural Society sixty years ago, in which, during the year, 140 prizes were given in the cottagers' classes. These prizes were mostly of small amount, but ten labourers won over £1 apiece, taking between them £20 11s. in prizes, the most successful cottager winning £4 9s. 6d. One of the first things to strike the examiner of the report referred to, indicating the changes that occur in horticulture and fashion through the introduction of new varieties which attract popular favour, is that the prize-lists contains no mention of either of the two families of plants that are the only ones for which flower-shows are now held at Plymouth, namely, Narcissi and Chrysanthemums; while the class provided in 1843 for the best collection of *Ericas* would nowadays be a difficult one to fill from private establishments. *S. W. Fitzherbert*. [Our correspondent also furnishes a long list, for which we have no space, of subjects for which prizes were offered in the various classes for stove plants, fruits, vegetables, &c. Ed.]

IMPATIENS HOLSTII.*

This species, which much resembles *I. Sultani*, was shown by Messrs. H. Cannell & Sons, Swanley, at the last meeting of the Royal Horticultural Society, when the species was recommended an Award of Merit. The seeds were originally introduced by Holst from German East Africa to the establishment of Messrs. Haage & Schmidt, of Erfurt. The botanical details are given in the works cited; for the rest our illustration, taken from the living plant, tells its own tale, except in the matter of colour, the flowers being scarlet. It is a native of Usambara and of Kilimanjaro, where it grows on the banks of streams at altitudes between 2,500 and 5,000 feet. It requires the same cultural treatment as the nearly-allied *I. Sultani*.

NURSERY NOTES.

HARDY PLANTS AT WINCHMORE HILL.

A visit at any season of the year to a hardy plant nursery is interesting, for almost always may some members of this popular class of plants be found in bloom, but the present may be regarded as one of the best times at which to see the bulk of these flowers at their best. Mr. Amos Perry's nursery at Winchmore Hill is about eight acres in extent, and it contains a choice selection of these floral beauties; the wonderful varieties of colour, form, and habit that these plants offer can be well appreciated in such circumstances. Here are to be found plants suitable for the border or the rockery, the water or the bog garden, as well as climbers for almost any phase of out-door gardening. The ease with which the generality of the plants may be cultivated renders them of additional value, while for furnishing cut flowers they stand unrivalled.

Mr. Perry has found the limited area at Winchmore Hill quite inadequate to grow his ever-increasing stock of plants, and he has, therefore, recently taken a larger piece of ground at Enfield, where sufficient space is available for the accommodation of a large nursery. About 32 acres of land on Enfield Chase have been acquired, on a good loamy soil, and this is now in course of preparation for the reception of the plants from the older nursery. This has occasioned much dislocation of labour and some disorder in the older nursery, but there was nevertheless plenty of good things to be seen that well repaid a visit that we made recently.

* *Impatiens Holstii*, Engler ex Warburg, in *Engler Abhandl. Preuss. Akad. Wiss.* (1894), pp. 48, 53, et in *Engler Pflanzen. Ost. Afric.* (1895), p. 254; *Bull. Soc. Toscane d'Ortic.* (1904), pp. 339, 24, fig. 23; *Rev. Hort. Belg.* (1905), p. 2, f. 4; *Ed. Mag.*, t. 8 29 in ed.

Some years since Mr. Perry commenced hybridising species of *Eremurus*, and the results are now to be seen in some grand varieties of these lordly plants. The seedlings are at present unnamed. *Eremurus robustus* crossed with *E. Bungei* has given some worthy novelties, quite an advance on anything we have previously seen

Others we were shown were of a pale pink shade, another was almost terra-cotta, while one was of a beautiful bright yellow colour, and still another of a bronzy-yellow. The pale yellow flowers of one of the seedlings was admirably set off by a distinct rose-coloured rib, and the ovaries of a glistening buttercup-yellow. The true *E. Bungei*

FIG. 7.—*IMPATIENS HOLSTII*: A TROPICAL AFRICAN SPECIES WITH SCARLET FLOWERS. Exhibited by Messrs. H. Cannell & Sons.

in this handsome Liliaceous genus. Some of the hybrids possess as tall an inflorescence as the first-named parent, others are intermediate between the two. One of the inflorescences approximated to 6 feet in height, with blooms of a creamy-yellow colour slightly suffused with rose-colour, especially in the younger flowers. There were several of this form, differing principally in the shade of colour, and the parent *E. robustus* may be said to have predominated in these types.

was shown us, and compared with a seedling that was much stronger in habit with flower-spike considerably larger and of an intense shade of yellow, a most beautiful plant.

We have no space to name all the other choice plants we observed in flower, but we may mention a few. *Crambe orientalis* is an excellent subject for a large bed, and develops a huge inflorescence of many hundreds of white star-shaped flowers, the whole forming a lax panicle

as much as 4 feet in diameter. A grand plant of *Tritoma caulescens*, that may not inaptly be likened to a *Yucca*, possessed eight strong growths and several spikes of flowers that are scarcely equal to those of *T. uvaria*. *Campanula collina* makes a very effective border plant, the habit is less than a foot in height, but the rich violet-purple blooms are produced in abundance. *Mimula Tilingi*, grown in a batch makes a pleasing show. *Dianthus Rose de Mai* was prominent in several quarters, and fully deserves a place in any collection of hardy flowers.

Helenium cupreum is a dwarf-growing species, and makes a good border plant, its flowers are orange-red in colour, the height being about 1 foot. *Phlox canadensis* was noticed in several improved forms; there was the lately certificated variety *P. c. Perry's Blue*, and another of rose colour, most floriferous—in fact, the plant resembled a bunch of flowers. *Tropæolum polyphyllum* has long decumbent growths studded with yellow flowers, and foliage as beautiful as the flowers, an excellent subject for trailing down a bank or over a rockery. *Asphodeline liburnica* is a tall-growing species with large yellow-coloured flowers. *Helianthella quinquerervis* is still uncommon in gardens, it resembles a dwarf-growing *Helianthus*.

Rudbeckia flava is another dwarf-growing composite; its flowers are superior to those of *R. Neumani*, and in addition it blooms earlier than that species. Perhaps the most notable of all the improved forms of the many beautiful plants seen was *Anchusa italica Perry's variety*. This striking *Boraginea* was of the loveliest shade of blue, such as is rare among plants and seen best in the species of *Gentian*. The flowers measure over $\frac{1}{2}$ -inch across, and are produced in profusion. *Heucheras* were represented by many improved varieties, ranging from almost white in colour to rich scarlet; one variety possessed a white throat that was edged with rose colour, a desirable combination.

We hesitate to touch upon the many bog and water plants that were brought to our notice, owing to considerations of space, but we will do so briefly. And here we may mention that our own flora furnishes as rich and varied an assortment of these plants as can be found anywhere. The yellow *Water-Iris*, *I. pseudo-acorus*, has scarcely a peer, and what is more fragrant than the Sweet-flag, *Calamus acorus*, or more graceful than the flowering Rush, *Butomus umbellatus*? No Orchid is more beautiful than the *Utricularia*, the Bladderwort; and what exotic can rival the leaves and flowers of *Ranunculus aquatilis*? The translucent leaves of *Potamogeton lucens* are every whit as beautiful as those of the rare *Ouvirandra fenestralis* that requires a stove temperature, while the Arrow-heads, the yellow Nuphar, Frogbit, *Lysimachias*, Mare's-tail (*Hippuris vulgaris*), together with the bog Orchids and a hundred-and-one other plants offer material in plenty to those who find delight in bog and water gardens. Of rarer forms we may allude to *Houttuynia cordata*, *Calla palustris*, *Ranunculus lingua grandiflora*, *Zizania latifolius*, and *Iris prismatica*.

We may mention a supposed natural hybrid between *Meconopsis cambrica* and *Papaver nudicaule*, that was found by Mr. Perry growing in one of the beds. The plant develops numerous Tulip-like flowers of a beautiful yellow colour, somewhat resembling the smaller flowers of *Meconopsis integrifolia*, and is a rich prize.

ENQUIRY.

PLANTS IN FRUIT-HOUSES.—What plants will grow and flower under Peach-trees or Vines in a glasshouse? I have a lot of fruit-houses, and would like to try to grow something under the trees. *Constant Reader*. [As a general practice this is not satisfactory. Ed.]

Obituary.

MRS. BURBIDGE.—Many of our readers will sympathise with Mr. F. W. Burbidge, of the Trinity College Botanic Gardens, Dublin, on the loss of his wife on the 23rd ult. An abdominal tumour necessitated an operation, but unfortunately the patient succumbed in a few hours. Mrs. Burbidge was in her fifty-seventh year, and was an ideal wife for a gardener, well versed in the literature of gardening, and taking so much interest in her husband's pursuits as to be a real and true helpmeet to him.

ARTHUR PERKINS.—The painfully sudden death of Mr. Arthur Perkins, senior member of the firm of Messrs. Perkins & Sons, Nurserymen and Florists, Coventry, occurred on Sunday, June 18, in Holy Trinity Church, Coventry, during divine service. Mr. Perkins was a native of Packington. He settled in Coventry many years ago, and founded the firm of Perkins &

THE LATE ARTHUR PERKINS.

Sons, which has gained many notable successes in floriculture, and has established a high reputation all over the country for floral decorations. Deceased was of a retiring disposition, and took no part in public matters.

The funeral took place at the cemetery at noon on the 21st ult., the remains of the deceased gentleman being laid to rest in the presence of a large number of his *employés* and friends and acquaintances. The coffin bore the following inscription:—"Arthur Perkins. Died June 18, 1905, aged 72 years."

WILLIAM LINDSAY MILNE.—The death of this excellent gardener and market florist grower in his fifty-ninth year has occurred at his residence, Lindsay Lodge, Hampton Hill. Rather less than a year ago Mr. Milne had the misfortune to lose his eldest son, who had gone to Australia for the benefit of his health.

Mr. Milne commenced his gardening career in Scotland, where he served in the gardens of the Duchess of Atholl, the Marquis of Tweeddale, and others. From Scotland he came to England, subsequently becoming head gardener at Beau Manor, Leicestershire. The early decease of his employer brought Mr. Milne to the nurseries of Messrs. Lee, of Hammersmith, and Messrs. Laing, then Downie, Laing & Laing, of Forest Hill. It

was during his stay at the last-named place that he decided to engage in the market florist's business.

Mr. Milne was one of the earliest market florists to grow the now well-known Rose General Jacqueminet for producing flowers for the button-hole, the buds realising 30s. per dozen in the wholesale market at that time. Mr. Milne also commenced cultivating the tree Carnation, the Gardenia, and other flowers. An excellent and painstaking gardener, his productions were ever of the highest excellence. It has often been stated that it is impossible to maintain a market nursery in good order, but Mr. Milne's nursery at Hampton Hill was a pattern of neatness. In local matters Mr. Milne took a keen interest.

The funeral took place on Monday last, at St. James's Church, Hampton Hill, when a large gathering of horticultural friends and others assembled at the graveside. Much sympathy is felt in the district for Mrs. Milne and her family in this the second bereavement within a year.

SOCIETIES.

THE ROYAL HORTICULTURAL.

(Concluded from p. 398.)

Floral Committee.

JUNE 20.—Some excellent varieties of *Anchusa italica* were shown by J. B. FORTESCUE, Esq., Dropmore, Maidenhead (gr., Mr. Page). They have large flowers, and are freer in habit than the type, but as an award has already been made to a similar variety, *A. i. grandiflora*, no further recognition was recommended.

Psoralea pinnata was shown in flower by the Hon. JNO. BOSCAWEN, Tregye, Cornwall. It is a Leguminous shrub, with blue-coloured, Pea-like flowers (illustrated in our columns on May 9, 1903, p. 301).

The distinct *Rhododendron*, *R. cinnabarinum*, was shown in the form of cut specimens by Mr. GILL, Tremough, Cornwall.

Mr. HENRY ECKFORD, Wem, Shropshire, brought a collection of Sweet Peas, with which his name is so intimately associated. Many of his newer novelties were included. We noticed the varieties King Edward VII., Countess Spencer (one of the very finest "pinks"), Romolo Piazzani (a new variety of exquisite light-blue colour), Scarlet Gem, Lady Hatherton, Gladys Unwin, &c. (Silver-gilt Banksian Medal).

Some well-grown *Gloxinias* and herbaceous *Calceolarias* were shown by Mr. G. H. Street, gr. to J. A. YOUNG, Esq., Stone House, Putney. The *Gloxinias* represented a good strain of these showy flowers (Bronze Banksian Medal).

A batch of *Streptocarpus* staged by Mr. E. Beckett, gr. to Lord ALDENHAM, Elstree, was as meritorious as any group in the Hall. This extensive collection contained plants of almost every shade of colour, and the quality of the plants was remarkable. Some of the specimens carried dozens of spikes of flowers (Silver-gilt Banksian Medal).

Messrs. KELWAY & SONS, Langport, Somerset, furnished the concert platform with a large collection of *Pæonies*, *Delphiniums*, and *Pyrethrums*. The *Delphiniums* were arranged in the centre of the group and at the back. Among the last-named were the varieties Norman Hurst (an exquisite shade of electric-blue) and *Primrose* (of pale cream-yellow colour), both worthy a place in any collection of these plants (Silver Banksian Medal).

Mr. R. H. BATH, Wisbech, made a bold display of *Pæonies* and Spanish *Irises*. The *Pæonies* were a remarkably fine lot, and included some new varieties, to two of which were granted awards. We may select the varieties *Lady Anna*, *Jules Calot*, *Victor Hugo*, *Her Grace* and *La Fiancée* as being some of the best examples shown (Silver-gilt Banksian Medal).

Mr. BEN. R. CANT & SONS, Old Rose Nurseries, Colchester, staged a group of cut *Roses*. Pillar and climbing varieties were numerous, and many single kinds were included. The variety *Mrs. W. J. Grant* was shown in good form. Several vases contained the new seedling pillar *Rose*, *Maharajah*, a single variety with deep purplish-red flowers (Silver Flora Medal).

Messrs. GEO. COOLING & SONS, Bath, displayed a large group of cut *Roses*, the whole of one of the central tables being entirely filled with the flowers (Silver-gilt Banksian Medal).

Roses of all types from the open garden were shown by Messrs. PAUL & SON, The Old Nurseries, Cheshunt. The flowers were arranged in vases, with a few specimen blooms shown in boxes. The varieties Carmine Pillar and Bardon Job were both presented in good form. The Dandy, H.T., is of the richest purple, comparable to velvet. *R. polyantha grandiflora* makes a good plant for covering pillars, pergolas, &c. Messrs. PAUL also displayed a flowering branch of *Fremontia californica*, and sprays of *Abutilon vitifolium* the latter with pale lavender-coloured flowers (Silver Banksian Medal).

Messrs. FRANK CANT & Co., Colchester, contributed a collection of Roses, having examples of many of the types of these popular flowers in first-class condition. The H.T. Papa Gontier was shown well; Lady Battersea is a pleasing variety; *R. macrantha* is quite one of the best varieties of the single type (Silver Banksian Medal).

A nice display of Roses was set up by Mr. GEORGE PRINCE, Longworth, Berks; the flowers were staged with good taste. Paul's Single White was shown in fine condition. Other good varieties were Lady Battersea, the favourite Carmine Pillar, Papillon, and Austrian Copper, the colour of the last-named being unique—a bronzy-orange or copper colour.

Messrs. CANNELL & SONS, Swanley, Kent, staged several good things. There were *Aquilegia* in number, and in many shades of colour; a batch of *Kalanchoe flammea* and *K. fulgens*, also some well-grown plants of *Gloxinias*, and specimens of *Lonicera Hildebrandiana* (Bronze Flora Medal).

Mr. CHAS. TURNER, Royal Nurseries, Slough, showed a fine lot of Carnation flowers, also flowers of varieties of *Pæonies*, &c.

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield, had the well-known greenhouse plant, *Diplacus glutinosus*, in very good condition; also plants and flowers of *Souvenir de la Malmaison* and other Carnations and *Ericas*.

Messrs. T. S. WARE, Ltd., Feltham, arranged capital flowers of Tree Carnations in elegant glasses.

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, showed excellent *Souvenir de la Malmaison* Carnations in many varieties. They also had two new *Primulas*, *P. sikkimensis* and *P. pycnoloba*. The first-named has drooping flowers of a yellow colour, the other is very curious, but of little value as a "garden plant."

Messrs. JAS. VEITCH & SONS had also a group arranged on the ground-floor, in which some of the choicer and rare-flowering trees and shrubs were shown, such as *Cistus florentinus*, *C. ladaniferus*, *Escallonia × exoniensis*, *E. × langleyensis*, *Carpenteria californica*, *Senecio Greyii*, *Magnolia Watsoni*, &c. One of the features of the group comprised branches of *Cornus Kousa* cut from trees 16 feet high at the Coombe Wood Nursery. These were thickly studded with flowers, their white bracts showing what an effective tree this species is (Silver-gilt Flora Medal).

Mr. H. B. MAY, Dysons Lane Nurseries, Upper Edmonton, made a feature of *Ixoras*, using small Ferns and *Selaginellas* freely as a groundwork to these flowers. *Ixora Fraseri* is a very effective plant for decorative purposes. We noticed a good specimen of *Allamanda grandiflora* freely flowering (Silver Flora Medal).

Messrs. T. CRIPPS & SON, Tunbridge Wells, Kent, contributed a group of Japanese *Acers*, and a few species of *Vitis*.

The best exhibit of stove foliage plants was that from Mr. L. R. RUSSELL, Richmond Nurseries, Surrey. The collection was a very representative one, and the species and varieties were all shown as thoroughly well-cultivated plants. They were arranged in an effective group upon the ground-floor, and presented quite a study in variety of colour, tint, and form of leaf. Such choice plants as *Anthurium crystallinum*, *Bertolonias*, *Marantas*, *Alocasias*, *Aralias*, *Codiaeums*, *Cordylines*, *Amasonia*, &c., were included; also good specimens of *Nepenthes sanguinea* and other species of the genus (Silver Flora Medal).

Messrs. W. M. BULL & SONS, King's Road, Chelsea, put up a collection of stove and greenhouse foliage plants. *Dracena Victoria* occupied the centre of the display. There were in addition good specimens of *D. John Luther*, *D. Prince Manouk Boy*, *Aralia Veitchii*, small *Cladadiums*, *Crotons*, &c. Adjoining the foliage plants were a number of Spanish *Irises* in many shades of colour.

Mr. RICHARD ANKER, Napier Road, Kensington, brought *Notera depressa* in small terra-cotta pots, the plants being covered with their pleasing red berries.

Messrs. W. CUTBUSH & SONS, Highgate, Middlesex, were represented by batches of the popular varieties of *Verbena hybrida*, *Richardia Elliottiana*, *Marguerite Queen Alexandra*, and *Erica Cavendishii*.

Messrs. GEO. BUNYARD & Co., Maidstone, Kent, staged a good exhibit of herbaceous flowers—*Campanulas*, *Heucheras*, *Irises*, *Pæonies*, *Delphiniums*, *Gladioli*, *Veronicas*, &c. A collection of well-grown Spanish *Irises* occupied one end of the display, the yellow *I. Cajanus* being remarkably fine. Sprays of *Andromeda pulverulenta* and *Gillenia trifoliata* were noticed.

From Mr. AMOS PERRY, Winchmore Hill Nurseries, London, N., there was shown a fine bank of hardy flowers, including most of the best of those now in season, some of which are referred to in our note on p. 14 (Silver Flora Medal).

Mr. M. PRICHARD, Christchurch, Hants, had a meritorious lot of hardy flowers. A good display of *Delphiniums* was prominent in the centre of the group; we admired the beautiful Cambridge-blue of *D. Belladonna*. These plants were backed by an inflorescence of *Crambe cordifolia* that spread for a considerable distance. A nice array of *Pæonies* was included, also flowering sprays of *Pentstemon heterophyllus* with flowers of a Borage-blue colour (Silver Banksian Medal).

Mr. R. C. NOTCUTT, Wood's Nursery, Woodbridge, showed a good assortment of herbaceous flowers of the usual kinds—*Irises*, *Pæonies*, *Poppies*, *Foxgloves*, *Delphiniums*, &c. *Polygonum Baldschuanicum* is quite one of the best species.

Messrs. THOS. S. WARE, Ltd., Feltham, Middlesex, staged a group of hardy flowers, *Pæonies*, *Delphiniums*, *Eremurus*, *Irises*, &c. *Spikes of Eremurus Bungei major* were shown in good condition; *E. robustus* was represented by several good inflorescences. An edging of dwarf-flowering subjects, such as *Campanula pulla*, *Dianthus neglectus*, &c., imparted a "finish" to the group. A tall-growing *Iris* of the ochroleuca type was shown named *I. Warei*.

Messrs. BARR & SONS, King Street, Covent Garden, London, brought a large collection of miscellaneous herbaceous flowers, *Lupins*, *Irises*, *Campanulas*, *Pæonies*, *Ixias*, *Poppies*, &c. *Arum Dracunculus* was included in the group, its powerful and very objectionable odour being very noticeable.

Messrs. J. CHEAL & SONS, Crawley, staged cut flowers from the herbaceous border; *Olearia macrodonta* was observed, also the trailing growths of *Tropaeolum polyphyllum*. A rose-coloured *Lupin* named *Lupinus polyphyllus roseus* was noticed.

Messrs. JOHN PEED & SON, West Norwood, London, S.E., staged a group of hardy and alpine plants. Hardy succulent plants were plentifully represented in the collection.

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, showed some excellent herbaceous flowers. The arrangement was good, the plants being placed on tiers of staging. *Liliums* were plentifully represented, *L. excelsum*, *L. Szovitzianum*, *L. monadelphum*, *L. Hansonii*, &c. The beautiful *Calochortus* was shown in many choice varieties. *Brodiaeas*, *Ixias*, *Heucheras*, *Campanulas*, *Irises*, and a host of similar plants contributed to the collection (Silver Banksian Medal).

Mr. JAS. DOUGLAS, Edenside, Great Bookham, brought a number of border *Pinks* and a choice collection of *Iris* flowers. Among the *Pinks* we admired *Snowdrift*, whose flowers are as large and handsome as those of a *Carnation*. They are pure white, with the exception of a suspicion of purple in the base of the petals. *Morna* is another good variety; the flowers are heavily blotched with pink on a white ground. The "Tree" *Carnation Fairy* has a well-formed flower of deep salmon-pink colour. Among the *Irises* the best varieties were *Maori King*, *Butterfly*, and *Black Prince*.

Messrs. BAKER, Lichfield Street, Wolverhampton, showed a very good strain of *Aquilegias*. The colours were exceptionally good, and the form of the best. At either end of the *Aquilegias* were groups of *Zonal Pelargoniums* in most of the improved varieties (Silver Banksian Medal).

Mr. B. LADHAMS, 60, High Street, Shirley, Southampton, staged a collection of border *Pinks* and a few other herbaceous flowers. *Dracoccephalum japonicum* "Blue Gem" is a nice form of this plant.

A collection of hybrid *Irises* and *Hemerocallis* was shown by G. YELD, Esq., Clifton Cottage, York. *Hemerocallis Tangierine* is of a desirable shade of colour, being of a richer yellow than the ordinary type.

Orchid Committee.

There was a very fine show of Orchids, the varied collection shown by the President of the Society, Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White), embracing the widest range, floral and botanical. The group, which secured a Silver-gilt Flora Medal, had at the back some fine specimens of *Thunia Marshalliana*. *T. × Brymeriana*, and *T. × Veitchiana superba*, each with several heads of bloom, and strong sprays of good forms of *Odontoglossum crispum*. The pretty *Masdevallias* included good examples of *M. × Rushtonii*, *M. × Bocking hybrid*, *M. × Ferrierensis*, *M. × Acis*, and others. Among the rare species, some of which will be found mentioned in the list of Awards, were *Acranthus carophorus* and *A. denti*, with singular greenish flowers; the singular little *Angraecum Smceannum*, a very light form of *Aerides Houlletianum*, *A. multiflorum Lobbii*, *Epidendrum Linkianum*, *E. pterocarpum*, *E. umbellatum*, *E. ochraceum*, *E. Watsonianum*, and other *Epidendrums*; a finely-flowered bright crimson *Renanthera Imshoottiana*, &c.

Messrs. CHARLES WORTH & Co., Heaton, Bradford, were awarded a Silver-gilt Flora Medal for a fine group, consisting principally of hybrids, among which was a selection of *Laelio-Cattleya × Fascinator*, *L.-C. × Canhamiana*, *L.-C. × Hippolyta* varieties, *L.-C. × G. S. Ball*, *L.-C. × Lady Miller*, *L.-C. × Aphrodite*, *Laelia × Diglyano-purpurata*, *L.-C. × Diglyano-Warscewiczii*. Other showy kinds were also displayed, with good *Odontoglossum crispum*, two very pretty *O. × excellens* (home raised), *O. × Harryanocrispum*, and other *Odontoglossums*: *Oncidium macranthum*, &c. An effective feature in the group was made by massing orange-coloured hybrids of *Laelia cinnabarina*.

Messrs. SANDER & SONS, St. Albans, secured a Silver-gilt Flora Medal for an effective arrangement of rare and showy Orchids, including good forms of *Laelio-Cattleya × Canhamiana*, *L.-C. × Martinetii*, *L.-C. × hutchleyensis*, &c. The forms of *Cattleya Mossie* included *C. M. kermesina*, a large pure white flower with fine yellow markings on the labellum; and some well-coloured varieties. A good selection of *Odontoglossum crispum*, *Miltonia vexillaria*, and other showy species were noticed; and among interesting and rare species a form of *Bifrenaria inodora* with cream-coloured flowers, *Anguloa uniflora aurea* with lemon-yellow flowers, &c.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), staged a good group that was rich in forms of *Cattleya Mossie* and *C. Mendeli*. Among the former were the white *C. Mossie* "Elijah Ashworth," with a light shading of lilac on the lip, and *C. M. Thurgoodiana*, a good flower with delicate pink sepals and petals, and showy lip; while among the latter the best were *C. Mendeli Pittie*, *C. M. Alfred Smece*, and *C. M. "Our Monarch"*. *Platyclinis filiformis* bore a profusion of its elegant sprays of yellow flowers; *Laelio-Cattleya × Martinetii ochracea* and *L.-C. Cornelia* were good; so also the selection of *Odontoglossum crispum*. Other plants noted were *Trigonidium spatulatum*, *Oncidium trinetrum*, *O. leucocheilum*, *Cypripedium callosum Sanderi*, &c. (Silver Flora Medal).

Messrs. HUGH LOW & Co., Enfield, staged a good group, in which were *Cattleya Mossie Bronze Queen* with a bronzy hue over the yellow of the disc of the lip; and a fine dark form of *C. Mossie*. Tall plants of *Vanda teres* were arranged at the back, with a very dark-lipped *Laelia purpurata*. Also noted were a fine specimen of *Coelogyne pandurata*, two clear white *Cattleya intermedia alba*, *Cypripedium callosum Sanderi*, *C. × selligerum majus*, *C. × gigas Cordeani*, &c. (Silver Flora Medal).

Messrs. STANLEY & Co., Southgate, staged an effective group of *Cattleya Mossie*, *C. Mendeli*, and *Odontoglossum crispum*, with plants of *Lycaste Deppei*, *Oncidium Gardneri*, *O. leucocheilum*, *Odontoglossum citrosimum*, *Miltonia vexillaria*, &c. (Silver Flora Medal).

Mrs. ERNEST HILLS, Redleaf, Penshurst (gr., Mr. Ringham), was awarded a Silver Banksian Medal for a well-grown and profusely-flowered group of *Miltonia vexillaria*.

FRANCIS WELLESLEY, Esq., Westfield (gr., Mr. Hopkins), showed *Laelio-Cattleya × Mrs. Reginald Brade* (*C. Schroderae × L.-C. × Aphrodite*), a pretty flower with white sepals and petals and violet-purple front to the lip; *Cattleya Mossie Miss Ethel Harting*, a good white flower with pale lilac marking on the lip in front of the yellow disc, and *Cypripedium Sanderi*, yellow spotted with purple, and resembling the tint of a large *C. concolor*, but with a broader labellum.

R. BRIGGS-BURY, Esq., Bank House, Acreington (gr. Mr. Wilkinson), showed a fine specimen with three flowers of *Cypripedium Lawrenceanum* Pleanum, Bank House variety, a very large-flowered form, with fine white dorsal sepal striped with emerald-green, the rest of the flower being soft light-green colour tinged with yellow. Also cut *Odontoglossum*.

R. BROOMAN-WHITE, Esq., Ardlarroch, Garelock-head, showed a good selection of cut spikes of *Odontoglossum crispum*.

W. A. BILNEY, Esq., Fir Grange, Weybridge, sent *Dendrobium Dalhouseianum* "Fir Grange variety," a distinct form, of a pale sulphur-yellow colour, with a large maroon blotch on each side of the lip.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, sent cut examples of two *Bulbophyllum*s and of *Tricheglottis fasciata*, which were referred to the Scientific Committee. [The specimens in question were submitted to the Scientific Committee without any information whatever. ED.]

Mrs. S. F. WHITFLAW, Amerden, Taplow, sent *Cattleya Mendeli* "Amerden," a showy variety with a fine mauve-crimson-coloured lip.

Scientific Committee.

JUNE 20.—Present: Dr. M. T. Masters, F.R.S. (in the chair); Revs. Professor Henslow and W. Wilks; Dr. M. C. Cooke; Messrs. Bowles, Shea, Gordon, Massee, Worsley, Worsdell, Douglas, Veitch and Chittenden (hon. sec.).

Pear Midge.—MR. BOWLES showed specimens of Pears attacked by the grubs of this fly, which also contained the larvæ of a small moth. These were referred to Mr. Saunders.

Fiddlers.—MR. GORDON showed specimens of these beetles (*Phyllopertha horticola*, L.), which are something like small cockchafers, and are reported to be very destructive to leaves and flowers. The larvæ feed on the roots of grasses, living for three years. They are very similar to the larvæ of the cockchafer, but much smaller.

Black Currant Mite.—MR. SHEA called attention to the fact that he had grown the variety of Black Currant, Boskoop Giant, for the past four years, and had not found any sign of mite upon it, although other varieties growing in close proximity were suffering from the attacks of the mite severely. Several other members of the Committee had had a like experience. Mr. Shea attributed the immunity of this variety to the fact that the buds were protected by relatively hard and impenetrable scale leaves, through which, in all probability, the mite could not pierce.

Disease of Cactacea.—MR. WORSLEY showed specimens of a scabby growth on the stems of *Phyllocactus*, which Mr. MASSEE undertook to examine.

Melons dying.—Specimens of Melon suffering from the attacks of eelworm at the roots came from Hatfield, Herts. The method of dealing with this troublesome pest was detailed in the *Journal of the Royal Horticultural Society*, 28, p. xxiv. (1904).

Vines diseased.—Vine leaves showing large yellow patches and somewhat papery in texture, from Vines bearing fruit much smaller than the normal were sent from Stafford. No fungi or insects were to be seen, but it was considered that the Vines (four out of nine in one house of Black Hamburgh) were suffering from some condition in the border that affected the roots, possibly choked drainage.

Primula pycnotoba (Bur. and Franch).—This newly-introduced species from W. China was shown by Messrs. Veitch. The plant bears an umbel of flowers with large, inflated calyces and small, deep orange-coloured corolla, scarcely exerted beyond the calyx-tube. The Committee desired to see this at a future meeting.

Origin of Garden Forms of Phyllocactus.—Letters on this subject were received from Messrs. Veitch, of Chelsea, and from M. de Laet, of Contich. The former stated that in the raising of their hybrids *Phyllocactus Ackermanni*, *P. crenatus*, *phyllanthoides*, and *P. "albus superbus"* had been used, as well as the best English and continental forms known when the raising of the "Veitch's hybrids" was commenced. M. de Laet, of Contich, wrote that the following come true from seed: *P. anguliger*, *P. Ackermanni*, *P. grandis*, *P. latifrons*, *P. phyllanthoides*, *P. strictus*, *P. crenatus*, and *P. Hookeri*, and may be regarded as true species. Hybrids are: i., *P. crenatus* × *Cereus grandiflorus* produced the Cooperi class; ii., *P. crenatus* × *P. phyllanthoides* (small flowers)

produced the rosa hybrids, such as *Vogeli*; iii., *P. Ackermanni* × *Cereus speciosus* have given the most beautifully coloured hybrids, such as × *Feastii*, × *Conway Giant*, &c.; and iv., all have been re-crossed and have given most interesting forms and colours. I myself obtained unexpected results. For instance, I obtained the Cooperi form, true in form, but of the finest pure red colour, and just last week (acellings from 1900 and 1899) two forms of the red Cooperi, but shaded with purple (cross Cooperi × *Conway Giant*). Another interesting cross is *Joseph de Laet* of two shades of blue. Usually all the *Phyllocacti* have sepals and petals going into one another softly, but in this the contrast is forced, the sepals being very dark and the petals of the softest shades. The value of this plant lies in the colour, not in the form; there are better forms (*Niobe* × *Docteur Hernu*).

Mr. WORSLEY made some remarks upon the foregoing, but reserved a fuller account of these plants for a future occasion.

Fruit and Vegetable Committee.

JUNE 27.—A meeting of a selected deputation from the Fruit and Vegetable Committee was held in the Wisley Gardens on the above date, Mr. G. Bunyard, V.M.H., presiding; also present were Messrs. E. Beckett, J. Cheal, S. Mortimer, G. Norman, V.M.H., and A. Dean, V.M.H.

The object of the meeting was to enable the deputation to see Peas and Tomatos, and to select such varieties as might be thought worthy of presentation to the Committee. The Peas selected were Sutton's Green Gem, 15 inches in height, early, and a first-rate podding Pea; Little Marvel, the earliest podding dwarf Pea in cultivation, sent by Messrs. SUTTON & SONS, JAS. CARTER & CO., and BARR & SONS; Laxton's Dwarf Gradus, Essex Wonder (a taller Pea), and Excelsior. Amerc, Duke of York, Edwin Beckett, all early, and some yet to pod, were doing well. Many varieties, however, had been severely injured by frost, and had not recovered. The ground is yet scarcely good enough to do Peas justice, and it is evident that a considerable amount of manure will be needed and labour expended to bring the upland soil into a good crop-bearing condition. Potatos are more promising. So far an effort to secure a large trial of white Broccoli is greatly handicapped by the quantity of black wire-worm in the soil. Probably a liberal application of gas-lime and soot will be helpful to get rid of a legacy of bad previous cultivation.

In the houses Tomatos are doing well. The earliest plants, put out in rows in the house borders, are fruiting finely, but the best at present undoubtedly is Sunrise, sent by Messrs. JAMES CARTER & CO. This may well be described as one of the heaviest cropping Tomatos yet seen. Large clusters of some ten to twelve good-sized, handsome dark red-coloured fruits are abundant, and the sample is excellent in form, size and colour. Also heavy cropping are Messrs. SUTTON & SONS' Earliest-of-All and Best-of-All, and Messrs. JAMES VEITCH & SONS' Ham Green.

THE HORTICULTURAL CLUB.

After the usual monthly dinner of this Club at the Hotel Windsor on Tuesday the 20th ult., at which Sir John Llewellyn presided, Mr. D. B. Crane read a paper on the "Beauty of the latter developments of the Pansy," illustrated by an exhibition of up-to-date examples. The most interesting feature of the paper and of the exhibits consisted of representatives of the *Violetta* or miniature section in the shape of extremely compact tufted plants suitable for rockeries and covered profusely with smaller flowers of the *Viola* type in many delicate colours. These are hybrids between *Pansies* and *Viola cornuta*, the result being the elimination of the lax spreading habit of the former, and the introduction into the latter of the varied Pansy tints. A further and very important result is additional hardiness, the *Violettas* being true perennials, while the Pansy often dies after flowering and is a difficult plant to maintain in form, especially under the drier conditions of southern Britain.

In the subsequent discussion considerable stress was laid upon the fact that the improvement was largely due to recourse having been had to the normal species *Viola cornuta* as the seed-bearer, instead of adhering to the practice common among both British and foreign hybridisers of continually crossing variety with variety.

The result of this last-named practice is a greater and greater lack of vigour and less of the natural habit of the species, so that although

splendid individual flowers are often obtained, this is at the expense of the floriferous nature of the plants, and, as a rule, when the amateur acquires them, their quality speedily depreciates under ordinary conditions and the promise of the first flowers is rarely subsequently fulfilled. In the *Violetta* section the caespitose habit of growth protects their roots from drought, and also facilitates propagation by the encouragement of rooting offsets. Mr. Crane justly gave the credit of these new productions to the late Dr. Chas. Stuart, M.D., of Chirnside, Berwickshire. This experimenter started by fertilising the wild Pyrenean form with the pollen of a garden Pansy named Blue King, obtaining twelve seeds therefrom in 1874. These yielded seedlings which were a complete revelation, though each retained the long dorsal spur or horn which gives the wild species its name. These seedlings were subsequently crossed with various coloured *Pansies*, flowers of every tint but yellow resulting, while the typical compact wild habit was retained and perpetuated. To prevent too close an approach to the known Pansy type, Dr. Stuart crossed some of the seedlings with the original *cornuta* hybrids, and the offspring produced flowers thrice the size of those of *V. cornuta*, much varied in colour and both prolific and floriferous. As the result of a trial of these plants at Chiswick in competition with *Violas*, no fewer than six First-class Certificates were awarded. These flowers however all retained the central rays which are regarded by floriculturists as a disfigurement, and it was not until 1887 that a perfectly rayless form appeared, accompanied by a pronounced Almond-like perfume. The pedigree of this plant is uncertain, as Dr. Stuart referred to it as a "chance seedling." This was named "*Violetta*," and from it originated the dwarf strain since so much elaborated. All through the paper the importance of making *V. cornuta* the seed-bearer was emphasised, as the opposite cross was apt to produce seedlings of the ordinary Pansy type. The general advance was graphically described, and the fresh varieties named, which have led up step by step to the present acquisitions; the paper was therefore of great utility not only to the Pansy-fancier, but to floriculturists generally on account of the principles of hybridising involved.

LINNEAN.

JUNE 15.—Professor W. A. HERDMAN, F.R.S., President, in the chair.

The Rev. JOHN GERARD, S.J., F.L.S., exhibited a series of lantern-slides of *Arum maculatum*, in disproof of the statements of Hermann Mueller and others as to the fertilisation of this plant by small flies, pointing out that these flies were not imprisoned by the abortive hair-like organs above the stamens, but that these visitants became stupefied by the nectar afforded by the ovaries, and were digested by the plant.

Dr. R. N. WOLFENDEN, F.L.S., laid before the Society a report on the *Collid Radiolaria*, being Part VI. of the series on Biscayan Plankton collected by Dr. G. Herbert Fowler during a cruise of H.M.S. *Research* in 1900.

On behalf of Professor Paul Pelseneer, of Ghent, Dr. G. H. FOWLER presented a report on the Mollusca (excepting Cephalopoda), forming Part VII. of the same series on Biscayan Plankton.

Sir DIETRICH BRANDIS, K.C.I.E., F.R.S., F.L.S., illustrated his paper, "Remarks on the Longitudinal Nerves and Transverse Veins in the Leaves of Bamboos," by a series of lantern-slides, displaying the longitudinal nerves of Bamboos, with the transverse veins, the latter easily observed in some species, but in the majority only to be detected by the microscope or after special treatment. These were shown to afford useful diagnostic characters in the case of genera which flowered irregularly and at long intervals. He also exhibited slides from transverse sections of Palm-leaves to show the absence of the mid-rib in such Palms as *Phoenix*.

A second paper by the same author dealt with "Some Remarkable Indian Under-shrubs," whose habit of life had apparently been modified by the effect of annual jungle fires, *Careya herbaea*, *Erythrina resupinata*, and *Grewia sapida* being specially mentioned. Experiments were now in progress at Dehra Dun, in the area protected from forest fires, and appearances now seemed to show that *Careya* and *Grewia* were changing their undershrubby habit and retaining the above-ground stems from year to year, possibly a reversion to original conditions of life.

The next paper, by Mr. W. P. PYCRAFT, A.L.S., "Notes on a Skeleton of the Musk-duck, *Biziura lobata*, with special Reference to Skeletal Characters acquired by Adaptation," was briefly explained by the author.

The last paper was one by Dr. M. T. MASTERS, F.R.S., F.L.S., "Notes on the genus *Widdringtonia*," treated as distinct from *Tetraclinis*, *Callitris*, *Actinostrobus*, with a revision of the genus, and the description of two new species.

ROYAL AGRICULTURAL.

JUNE 27.—If the show at Park Royal is not a success this year the weather cannot be blamed. At any rate on the opening day (Tuesday, and up to Thursday) the conditions were all that could be desired. Up to 1 P. M. on the first day the number of those who had paid for admission amounted to 1,673, as compared with 1,288 up to the same hour last year. We trust these figures may be taken as prophetic of a successful meeting (though subsequent reports are not encouraging). The place is so vast that a thousand or two of people do not make much show in it. The exhibits for the most part interest agriculturists only, but there are a few which concern horticulturists also. First and foremost in this relation are the departments for Forestry and Education. These two are side by side, not far from the pigs! The collection of Osiers and Willows for basket-making and similar purposes made by Lord EGERTON of TATTON deserves notice, and the specimens and photographs shown by the Earl of YARBOROUGH from Brocklesby Park appeal to the planter. The exhibit of Larch and other timber subject to the creosoting process is very striking. The photographs of woods and of single trees illustrative of continental and British systems of sylviculture attract attention, but on the whole this department is not so good and so representative as that of last year.

A similar remark may be made as to the Agricultural Education section. Here we have from ROTHAMSTED, from READING, and various agricultural colleges and stations experiments showing in concrete form the results of omitting or of applying certain manures. It would be difficult to overrate the importance of these experimental results. We are sorry our limitations only permit us to mention them, but as these lines will reach but few before the show closes, it would not be of much value to dilate upon details. We may however, suggest that on another occasion it would be well for the exhibitors to prepare a short statement of the nature of the exhibit, its aims, and the results obtained, which could be given to those interested. In so large a show, and amid such a multiplicity of detail, it is impossible for any reporter in his necessarily hurried survey to grasp the meaning of all that he sees. The Rothamsted exhibit shows very clearly the effect of lime and of its absence on the constitution and nature of the herbage. The Cambridge University agricultural department shows hybrid Wheats and the results of investigation into the chemical composition of Mangels. The MIDLAND AGRICULTURAL INSTITUTE had a particularly interesting exhibit showing the results of experiments with Beans, Peas and other leguminous crops with and without nitrogen, and with or without the German and American bacterial inoculating material. The HARPER-ADAMS COLLEGE, among other things, has a series of model hedges live and dead.

THE METEOROLOGICAL SOCIETY and the METEOROLOGICAL OFFICE have an interesting set of instruments, and some most instructive diagrams.

Placed, some near the forestry pavilion, others scattered throughout the grounds, are collections of living trees and shrubs. Thus Messrs. FISHER, SON & SIBRAY have a beautiful group of ornamental trees and shrubs; *Picea Omorika*, one of the more newly introduced Spruces, and one of great interest, is recommended for planting in exposed places, as it bears exposure to the wind better than many others. The golden form of *Taxus adpressa* is very attractive, and *T. coccinea* "The Lady" is so called from the grace of its appearance. *Ilex crenata*, a Holly with tiny leaves, is recommended for smoky localities; *Rubus nana aurea* is a prettily variegated Bramble, and *Sorbus himalaica* is a fine *Pyrus* of the Aria section.

Messrs. KENT & BRYDON, of Darlington, have a similar group of ornamental deciduous trees and Conifers.

Mr. L. R. RUSSELL, of Richmond, has a group of ornamental shrubs near the main entrance; *Aralia manchurica* is very beautiful in this group.

Hard by Messrs. CUTBUSH show their cocks and hens and other whimsicalities cut out of Box. In spite of their artificial appearance the foliage is clean and healthy.

Messrs. LITTLE & BALLANTYNE have an exhibit of shrubs, together with *Verbenas* and other flowers.

In the exhibit of Messrs. DICKSON & ROBINSON, in addition to Mangels and Potatoes, are Irises and a grand display of *Verbena Miss Willmott*, a variety which has become so popular that it is to be seen in almost all the stands.

The ONE-AND-ALL SOCIETY, in addition to seeds of various kinds, show *Begonias*, Tomatoes, and other things likely to attract the eye of the visitor.

Messrs. DICKSON, BROWN, & TAIT show seeds; and Messrs. DICKSON, of Chester, have, in addition to agricultural seeds, grasses, &c., a small group of hardy ornamental shrubs.

Messrs. WEBB, besides the exhibits that we expect to find, have a fine display of cut flowers of Sweet Peas.

Messrs. CARTER & CO. have Mangels (*Mangels* in June!), and a fine variety of Clovers and Grasses in growth, with *Begonias*, *Gloxinias*, *Lilium lancifolium*, &c.

Messrs. SUTTON have the usual exhibition of finely-selected roots and seeds, together with a glass case of

their fine strain of *Gloxinias*. A brilliant scarlet Sweet William, called Grenadin Scarlet, is noticeable in this collection, as well as a double blue *Nigella*, to which the name of Miss Jekyll is attached. In their collection of living Clovers is one *Trifolium pannonicum*, which is very bold in appearance, but what its value as a forage plant may be we do not know. Garden seats, summer-houses, and garden appliances are shown by Messrs. Inman & Co., of Manchester; J. P. White, of Bedford; Messrs. Merryweather, Strawson, and others. The two last-named firms exhibit various forms of spraying apparatus worthy the notice of fruit growers, whilst, if the visitor should be in want of a figure-head for his back-garden, Messrs. Castle will supply colossal figure-heads of Wellington and other heroes.

RICHMOND HORTICULTURAL.

JUNE 28.—The thirty-first annual show of the above Society was held on the foregoing date in the Old Deer Park. The weather was warm and summer-like. The exhibition was an excellent one taken as a whole, although some of the classes were perhaps not so fully represented as in some former years. Roses and floral decorations were exceptionally well shown, some of the specimens in the classes for the former being of excellent quality. Exhibits of plants and flowers in the group classes were also excellent, and some good vegetables were shown, the Cottage and Allotment Classes being well contested with examples of good produce.

In addition to the competitive classes some notable exhibits were staged by members of the trade, that of Messrs. T. S. WARE & Co. being not only extensive, filling as it did a considerable area in one of the large tents, but of a most meritorious quality, and indeed the finest exhibit in the exhibition.

Mr. H. L. RUSSELL, Richmond, also staged a good non-competitive group, having stove and greenhouse foliage plants in excellent condition. The exhibition was accommodated in four large marquees.

PLANTS.

The groups of plants in one of the large central tents made a very pleasing feature. The 1st prize for a group of plants not to exceed 100 square feet in area was won by the Hon. Mr. Justice SWINFEN EADY, Otlands Lodge, Weybridge (gr. Mr. J. Lock). The group was arranged in a semicircular manner, and was set up with exceptional taste. Handsome stove and greenhouse foliage plants were interspersed with such subjects as *Liliums*, *Ixoras*, *Gloxinias*, *Campanulas*, *Trachelium cœruleum*, *Carnations*, &c. The 2nd prize group was also a good exhibit; this was shown by Mr. H. E. FORDHAM, Nurseryman, Twickenham. 3rd. Mr. W. VAUSE, Leamington.

Mr. VAUSE was 1st in the class for six Palms in not fewer than three varieties, and also was 1st for six foliage plants, distinct varieties.

In the class for a smaller group of plants measuring 60 square feet, Sir FREDERICK WIGAN, Bart., was 1st with a nicely arranged group comprising *Codiaeums*, *Dracenas*, *Anthuriums*, *Carnations*, *Cattleyas*, *Odontoglossums*, *Liliums*, *Gladioli*, &c. The 2nd prize group in this collection was almost solely composed of foliage plants; it was set up by Mr. Hicks, gr. to C. BARTLETT, Esq., East Sheen.

The best six Orchids were shown by Sir FREDERICK WIGAN, Bart., whose exhibit was far ahead of the only other collection, staged by Mr. Wm. VAUSE, Leamington. A pair of *Lælio-Cattleya canhamiana* var. in the 1st-prize group was grand. A good dark blotched *Odontoglossum* (unnamed) was shown by Mr. VAUSE.

Mr. H. Hicks, gr. to C. BARTLETT, Esq., was successful in the class for nine *Gloxinias*, and was also 1st in the class for six plants, the prizes for which were given by Messrs. Sutton & Sons. Mr. W. Hill, gr. to G. ATKINS, Esq., Manaton, East Sheen, was 2nd for nine *Gloxinias*.

The premier prize for twelve tuberous-rooting *Begonias* fell to Mr. H. Fleet, gr. to A. ELSEE, Esq., Burlington House, Hampton Hill, 2nd going to Dr. SCOTT, The Old Palace, Richmond (gr. Mr. R. Johnson). *Begonias* on the whole were but of mediocre quality.

The prizes offered by Thomas Skewes-Cox, Esq., M.P., for the best collection of Sweet Peas in six distinct varieties were awarded to the Rev. A. WELSH OWEN, Old Palace, Richmond (gr. Mr. J. Hurrell), Sir. R. W. BULKELEY, Bart. (gr. Mr. T. H. Bolton), and Mr. R. RAPEL, York Road, Richmond, who were 1st, 2nd and 3rd in the order named.

ROSES.

These flowers as above mentioned were a feature of the exhibition. The premier prize was in Class 10, and this carried with it the Gunnersbury Park Challenge Cup, presented by Leopold de Rothschild, Esq., Gunnersbury Park, Acton, W. Mr. B. R. CANT, The Old Rose Garden, Colchester, was the successful exhibitor, and his collection was indeed good, but so closely followed by the 2nd prize collection that they were only separated by one point. If we select any flowers from the 1st prize group as being specially notable we must include *Bessie Brown*, Mrs. Ed. Mawley, Mrs. John Laing, and *Horace Vernet*. Messrs. PRIOR & SON, Colchester, were 2nd.

In the class for twenty-four distinct varieties of Roses, Messrs. G. & W. H. BURCH secured 1st place with large flowers; followed by Messrs. B. R. CANT & SONS, Colchester, 2nd.

Messrs. BURCH were 1st with twelve distinct varieties, having excellent examples of *Bessie Brown* and *Mildred Grant*. 2nd, Messrs. D. PRIOR & SON.

The best twelve Hybrid Tea Roses of one variety were Messrs. PRIOR's dozen flowers of Mrs. John Laing.

The premier twelve Teas of one variety were those staged by Messrs. PRIOR, the variety being Mrs. Ed. Mawley.

Class 18, for twenty-four bunches of hardy herbaceous flowers was represented by three good exhibits that must have required careful judging. The victors were Messrs. PAUL & SON, Cheshunt, 1st, who showed *Coreopsis grandiflora*, *Ligularia macrophylla*, *Dracocephalum japonicum*, &c. 2nd, the Earl of DYSART, with a very bright display.

Table decorations made an excellent feature, the whole of the exhibits being of a high order of merit. Miss C. B. COLE, The Vineyard, Feltham, had the best basket of cut flowers and foliage. The best bride's bouquet was also shown by Miss COLE, who also took 1st in Class 24 for the most tastefully-arranged table decoration in the modern style.

FRUIT AND VEGETABLES.

Class 19, for six dishes of fruit, distinct kinds, was represented by two exhibits only, those from Mr. Justice SWINFEN EADY and the Earl of DYSART respectively, who were awarded 1st and 2nd prizes in the order named. The 1st prize carried with it a valuable cup presented by Lady Max Waechter, in addition to a monetary prize of £3 10s. The dishes in the premier group included *Alexandre Noblesse* Peach, *Melón Royal Jubilee*, the *Dryden Nectarine* (excellent examples), and *Foster's Seedling* and *Black Hamburgh* Grapes.

The best three bunches of Black Grapes came from the Earl of ONSLOW's gardens (gr. Mr. H. W. Black). The variety shown was *Madresfield Court*. They were good, well-formed bunches, but too early in the season for perfection of finish. ALFRED BENSON, Esq., Upper Gattin Park, Merstham, Surrey, was 2nd with *Black Hamburgh*. 3rd, W. GREENWELL, Esq., Marden Park, Surrey (gr. Mr. W. Lintott), with the same variety.

Three good bunches of *Foster's Seedling* secured for Mr. Justice SWINFEN EADY the 1st prize for white Grapes; W. GREENWELL, Esq., coming a good 2nd with the same variety, but having slightly inferior shaped bunches, and the berries less ripened. The Earl of ONSLOW was 3rd with *Buckland Sweetwater*. Six exhibitors entered in the class for black, and five in that for white Grapes, and the competition was keen.

The best Melon was staged by Mrs. LEWIN PHILLIPS, East Sheen (gr. Mr. T. Cooper), who showed a white-fleshed variety named *Blenheim Orange*.

One dish of Nectarines only was represented in Class 33. These came from Justice SWINFEN EADY's gardens, and were awarded 1st prize, a position the quality merited.

Mr. Justice SWINFEN EADY also secured 1st for Cherries with *Black Bizarreau*, in which class he was again the only representative.

The Earl of DYSART was 1st for two dishes of Strawberries with the varieties *Leader* and *The Laxton*.

For a collection of vegetables of twelve distinct kinds there were three entries, the Earl of DYSART being an easy 1st, having *Ellam's Early Cabbage*, *Magnum Bonum Cauliflowers*, *Early Giant Pea*, *Telegraph Cucumbers*, &c. 2nd, WALTER SULLY, Esq., Eddington Hall (gr. Mr. W. H. Clarke). Potatoes and Peas were shown well in this group.

In the class for a group of vegetables of nine distinct varieties, the prizes were given by Messrs. CARTER & Co., Holborn. The collection shown by Mr. T. H. Bolton, gr. to Sir R. W. BULKELEY, Bart., Beaumaris, North Wales, was 1st, and equalled any in the show. Cauliflowers, Carrots, Peas, Onions, &c., were all in first-class condition. 2nd, Mr. W. ASKEW, 87, Manor Grove, Richmond, but the quality was much below that of the 1st prize group.

In the class for the allotment holders in the Society's district were some good vegetables, Mr. RICHARD KEENE taking the 1st place with some excellent produce, notably Onions, Peas, and Carrots.

Mr. Justice SWINFEN EADY secured 1st place for Tomatoes, having a commendable dish of the variety *Sutton's Al*. 2nd, Mrs. LEWIN PHILLIPS, with the variety *Duke of York*. These two comprised the only entries in this class.

NON-COMPETITIVE EXHIBITS.

Messrs. T. S. WARE, Ltd., Feltham, Middlesex, brought a huge display, almost filling the central staging of one of the large tents. They had Roses, herbaceous flowers, *Begonias*, *Nymphaeas*, *Carnations*, &c., set up in first-class style, quite a show in itself. Mr. RUSSELL, Richmond, staged a choice collection of foliage plants, the members being well grown and shown to advantage. It included some of the best

MARKETS.

COVENT GARDEN, June 28.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

REMARKS.—The supply of Southampton Strawberries is abundant, but a great quantity shows signs of the effects of wet weather. There are plenty arriving also from Kent, Middlesex, Surrey, and Cornwall. Peaches and Nectarines were very plentiful in the first part of this week, but have risen in price owing to a sudden short supply of best quality. Figs (green) again command a very slow trade, owing to large quantities being on the market. English Tomatos have again become cheaper owing to the hot weather. Trade generally has improved considerably.

POTATOS.

Dunbars, 80s. to 90s.; various, home-grown, 60s. to 90s. per ton; seed in variety.

COVENT GARDEN FLOWER MARKET.

THE season seems to be closing fairly well. The demand for good flowering-plants still continues, and large quantities have been disposed of during the past week. Some growers have sold all their spring plants and their stands are empty. Large supplies still come in, but much that is now seen is inferior in quality, and as many of the costers are now buying Strawberries and other fruit instead of plants, there is not such a good "clear out" trade being done. On Saturday and again on Tuesday there were few good plants left on the market, and this morning trade has been moderately good. Crimson Rambler Roses have sold well, the best and largest plants realising 7s. 6d. each. The new Rambler Roses will take a long time to displace the first favourite. I think that known as Lady Gay is the most likely to become popular. Dorothy Perkins, though very pretty, is not quite a popular colour. There is still a large trade done in Marguerites. Good plants of the white and yellow varieties have sold well at fair prices. There are not so many plants of Chrysanthemum setegum on the market now, and good prices are therefore maintained. Fuchsias are plentiful, and most of them of good quality. Hydrangea paniculata varies in quality; some plants are very good, while there are many which have not finished their flowers off well, besides being thin in growth. Some very good plants of Lilium longiflorum are seen, also L. speciosum rubrum; but it is difficult to fix prices for these as some are sold very cheaply. Show Pelargoniums are still plentiful and good. Zonal Pelargoniums are over-done, but some varieties sell well. Ivy-leaved varieties also sell

decorative species of Alocacias, Nepenthes, Dracenas, Anthuriums, Ananassa sativa, Araleas, Marantas, &c. Mr. W. THOMPSON, Sheen Nurseries, Sheen, arranged semi-circular groups of plants at either end of the tent containing the plant groups. They were chiefly foliage plants, but there were interspersed such things as Astilbe (Spirea), Hydrangeas, &c.

Sir FREDERICK WIGAN, Bart., Clare Lawn, Upper Sheen (gr., Mr. W. H. Young), set up a splendid assortment of Orchids. We noticed a pan of Cologyne Schilleriana, Phalenopsis grandiflora Rimestadtiana, Cypripedium Harrisonianum superbum, &c.

The Countess of DUDLEY (gr., Mr. H. Wright) had a small stand of Roses, Delphiniums, &c.

Mr. A. LL. GWILLIM, New Eltham, Kent, contributed some excellent tuberous-rooting Begonias, also Gloxinias and Anemones. Messrs. W. & J. BROWN, Stamford and Peterborough, showed Roses and greenhouse flowers. Messrs. GEO. JACKMAN & SON, Woking, Surrey, brought some nice vases of Sweet Peas, Spanish Irises, Delphiniums, Peonies, Roses, &c. Messrs. J. PEED & SON, West Norwood, London, showed a batch of Gloxinias, also vases containing excellent Sweet Peas. Messrs. JONES & SONS, Shrewsbury, also had a collection of Sweet Peas. Messrs. DOBBIE & CO., Rothesay, N.B., showed meritorious Violas and Pansies, and some good Sweet Peas.

GARDENERS' DEBATING SOCIETIES.

BATH AND DISTRICT GARDENERS.—The members of the above Association held their annual outing on the 22nd ult., when upwards of fifty journeyed in brakes to Clevedon. The party first visited Long Ashton Court, the beautiful residence of Lady Smyth, being conducted over the spacious and well-kept gardens and grounds by the head gardener, Mr. Noble. From Ashton Court the party drove to Tyntesfield, one of the finest gardens in Somerset. In this instance also, the head gardener, Mr. Wilkinson, undertook the task of showing the members the chief features of interest. General regret was expressed that more time was not available to examine more thoroughly the gardens and grounds. Another drive through beautiful scenery brought the party to Clevedon, where a capital dinner was partaken of at the Towers Hotel. The outing was generally regarded as the most enjoyable spent by the Association.

CROYDON AND DISTRICT HORTICULTURAL.—An interesting lecture on "The Distribution of Plants by Adaptation," was delivered on Tuesday, 27th ult., by the Rev. George Henslow, Professor of Botany to the Royal Horticultural Society. Mr. J. J. Reid (President of the Society) occupied the chair. Professor Henslow said protoplasm had the power of adapting itself to whatever the conditions were, and set to work to build up tissues, cells, organs as they called them, adapted to the new conditions. Plants changed generation after generation until they reached those forms which were best suited to their conditions of life. Wherever they went the plants were always adapted to their localities, and they found precisely the same internal structure corresponding to the external conditions. A number of excellent lantern slides showed several points relative to the adaptation of plants, which the lecturer elucidated. A vote of thanks to the lecturer was adopted with great cordiality, on the proposition of the Chairman.

SCHEDULES RECEIVED.

SOUTH SHIELDS HORTICULTURAL SOCIETY.—The Committee of this Society are doing their best to make the exhibitions meet with popular favour. This year's schedule for the exhibition to be held on August 30 and 31 shows that the value of the prizes in nearly all classes has been advanced, and the amount now offered exceeds upwards of £120. In addition to this a Challenge Cup of the value of ten guineas is included in the 1st prize for stove and greenhouse plants. It is the earnest desire of the Committee to get exhibitors from the South to compete. Mr. Geo. Olgilvie, 33, Thomas Street, South Shields, is the Secretary, from whom further particulars may be obtained.

SHEFFIELD FLORAL AND HORTICULTURAL SOCIETY'S Sixth Annual Exhibition, to be held on Saturday, August 19, 1905, in the grounds of Holly Court, Ecclesall, Sheffield.

BOLTON HORTICULTURAL AND CHRYSANTHEMUM SOCIETY'S Nineteenth Exhibition, to be held in the Albert Hall, Bolton, on Friday and Saturday, November 17 and 18, 1905.

HEREFORD AND WEST OF ENGLAND ROSE SOCIETY'S Exhibition, to be held in the Shire Hall, Hereford, on Wednesday, July 5, 1905.

CHIPPING NORTON AND NORTH OXON ROSE SOCIETY'S Exhibition at Ivydene, Chipping Norton, on Thursday, July 13, 1905.

GARDENING APPOINTMENTS.

Mr. J. W. HARPER, late Foreman at Apley Castle, Wellington, Shropshire, as Gardener to BASIL WM. VALENTIN, Esq., Cilgiff, Llanelly, Carmarthenshire. Mr. F. STANBRIDGE, for the past fifteen months with Messrs. J. Laing & Sons, Forest Hill Nurseries, previously four and a half years Foreman at Selsdon Park, Chobson, as Gardener to Lord ERNEST HAMILTON, Shantock Hall, Bovingdon, Hemel Hempstead. Mr. ARTHUR FRY, for the last six years General Foreman at Gateacre Grange Gardens, Liverpool, as Gardener to E. J. JOHNSTONE, Esq., Burrwood, Groombridge, Kent.

well when in good condition, but there are now many rough-looking, straggling plants. Mignonette is not over-plentiful. Good Cannas are still procurable. Well-flowered plants of *Tropeolum* (dwarf) in both yellow and crimson varieties are seen, but these have come too late to be of much value. The Kalosanties do not now sell so well, excepting the scarlet variety. In Ferns, Palms, and other foliage plants, trade is not very brisk.

CUT FLOWERS.

Trade is very uncertain, and supplies all round are over-abundant. The fruit trade affects the casual trade for flowers more than it does for plants. The shop trade for flowers as well as that of the hawkers falls off when Strawberries and Cherries become plentiful. Yet there is still a moderate trade for some things. The best Roses sell well, but we are now getting large quantities of out-door flowers, and most of these have the outer petals damaged, and, independently of this, the demand is not equal to the supplies. Carnations are in excess of all demands; even the best blooms do not sell well. The very best "Malmansons" make high prices, but those of second quality are not wanted. *Lilium longiflorum* are over-plentiful, and there are still Callas obtainable at moderate prices. Eucharis flowers will not sell even at 1s. per dozen, but a few days may make a considerable difference in the price. *Stephanotis* also moves slowly. All short-stemmed flowers seem to depreciate in value. At the close of the market this morning there remained large quantities of cut flowers. All round the market the dull time has set in before growers have cleared their season's stock. A. U., Wednesday, June 28.

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Vegetables: Potatoes, old, 2s. 4d. to 3s. 3d. per cwt.; new, Jersey, 9s. to 9s. 6d. do.; St. Malo, 9s. 6d. to 10s. do.; Turnips, 6d. to 8d. per dozen bunches; Carrots, 9d. to 10d. per dozen bunches; Cucumbers, 1s. 9d. to 3s. per dozen; Onions, foreign, 2s. to 4s. per bag; Parsley, 4d. to 6d. per dozen bunches; Lettuces, 4d. to 5d. per dozen; Cauliflowers, 1s. 9d. to 2s. 6d. do.; Cabbages, 4d. to 5d. do.—Fruit: Oranges, Valencia, 8s. 3d. to 10s. 9d. per case; Apples, Tasmanian, 10s. 6d. to 13s. 6d. per box; Lemons, Palermo, 6s. 3d. to 1s. per case; Bananas, 4s. to 7s. per crate; Tomatos, Valencia, 8s. to 9s. 6d. per case.

EDINBURGH.—Grapes, English, 1s. 9d. to 2s. per lb.; do. Belgian, 1s. 4d. do.; Lemons, Palermo, 7s. 6d. to 10s. 6d. per box; Apples, Australian, 13s. to 15s. per box; Bananas, 5s. 6d. to 10s. per bunch; Nuts, 18s. 6d. to 40s. per cwt.; do. Barcelona, 35s. to 28s. 6d. per bag; Figs, 9d. per dozen; Walnuts, Italian, 6s. 3d. per stone; Dates, Hollowil, 15s. 6d. per cwt.; Tomatos, Guernsey, 5s. 4d. to 6d. per box; Onions, Egyptian, 4s. per cwt.; Carrots, 1s. doz.; Gooseberries, English, 2½d. to 3d. per quart; Potatos, Canary, 10s. 6d. to 12s. per cwt.

DUBLIN.—Vegetables: Cabbages, York, 3s. to 8s. 6d. per load; Cauliflowers, 9d. to 1s. 6d. per dozen; Parsley, 2s. 6d. to 3s. 6d. per bag; Parsnips, 2s. 3d. to 2s. 6d. per cwt.; Onions, 4d. to 5d. per bunch; Rhubarb, 2s. to 2s. 2d. per dozen; Turnips, 2d. to 5d. per bunch; Salad, 4d. to 5d. per dozen; Carrots, 1s. to 1s. 2d. per dozen; Potatos, New, sandy, 5s. and clay, 6s. per cwt.; Old, finishing at 2s. to 2s. 6d. do.; special lots at 3s. to 3s. 2d. do.

ANSWERS TO CORRESPONDENTS.

ANTHURIUM PROCRASKIANUM × *Berlin*. According to Dr. Engler's Monograph of the Pothoideae, in *Das Pflanzenreich*, just received (June 27), this was described by Makoy in the *Journal de la Société d'Horticulture de France* in 1886, No. 94, p. 83.

ANTS IN GLASSHOUSES: W. B. J. You appear to have tried all the simple and safe remedies, some of which in our own case have proved effectual. In adopting stronger measures you must bear in mind that the greatest care is necessary, because they are themselves or they contain virulent poison. Thus you might pour small quantities of carbolic acid about their haunts, or apply what is known as the Ballikrain Ant Destroyer, the basis of which is arsenic in large proportions, which you may be able to obtain from a wholesale chemist.

DAMPNESS IN GREENHOUSE: W. N. M., Bristol. Cover the floor with a layer of concrete. If any trees are likely to shade the house let them be cut back. Leave just a little ventilation open at night whenever the conditions of the weather outside will allow of this. Do not throw water about or syringe the plants late in the afternoon.

DELPHINIUM: J. McC. Although white forms of this flower are not common, there are such varieties to be had, of which probably the best

is Beauty of Langport. You should compare your flowers with this or some other good white variety, and see if it is superior.

GLADIOLUS FAILING: R. Mac. We find no trace of either fungus or mite. Another season they will probably develop normally.

GRAPES: Sussex Hambro. A very bad case of anthracnose, caused by *Gloeosporium ampelophagum*. The plants should be sprinkled with flowers-of-sulphur mixed with one quarter its weight of powdered quicklime.

LETTUCES: H. J. S. You must first send us specimens of the insect, which is probably an aphid.

MADRESFIELD COURT GRAPE: Zero. Read Mr. Jordan's remarks in the weekly Calendar on p. 8, column 1.

NECTARINE FRUITS: J. G. D. We believe the shrivelling to have been caused by the sun's rays reaching the fruits when their skins were in a more or less damp condition.

NAMES OF FRUITS: In forwarding Peach or other soft fruits to be named, it is imperative that two specimens of each variety be sent, also a shoot with foliage, as identification is sometimes established by the character of the glands. The fruits should be gathered just before they are quite ripe. Wrap each fruit in tissue-paper, and pack them very carefully in soft material and in a wooden box that will not be likely to get crushed in the post. Pack sufficiently tightly to prevent the fruits from shaking in the box. In the case of Peaches it should be stated whether the tree produces large or small flowers. Do not post at the week-end, when delay may be reasonably expected.—E. B.

The two Peach fruits have arrived in a crushed condition with the skins broken. This was due to packing them too loosely in the box, which allowed of their being shaken during transit. The particulars you give would otherwise have been very useful.—W. C. Upon comparing your Peach with Stirling Castle, we felt convinced you had it rightly named, as the fruits were quite similar. Since you have given us a description of the flowers, we have now no hesitation in saying it is Stirling Castle.

NAMES OF PLANTS: Paddy. *Olearia stellulata*, *Polygonum complexum*, *Ozothaunus rosmarinifolius*.—R. F. *Phytolacca decandra*.—E. S. *Polypodium Dryopteris*, *Kalmia latifolia*.—W. S., Reading. *Carex stellulata*.—A. J. A., Leeds. 1, *Achillea macrophylla*; 4, *Fuchsia gracilis* var. *variegata*.—E. R. F. *Hyoscyamus niger*, common *Heubane*.—A. *Brassica sinapis*, *Charlock* or *Wild Mustard*.—C. J. *Phacelia tanacetifolia*.—W. F. *Platystemon californicum*, sometimes called *Californian Poppy*.—L. L. *Salvia Horminum*.—E. V. B. *Erigeron philadelphicus*.—W. T. *Cornus suecica*, nowhere common in Britain.—Enquiry, Enfield. They seem to be all *Iris ochroleuca*.—W. Y. *Muscari comosum*, a variety in which the flower-stalks become deeply coloured while the flowers are abortive. A very old inhabitant.—No Name, Basingstoke. 1, *Pyrethrum Parthenium*; 2, *Dianthus caryophyllus*; 3, *Saxifraga Wallacea*; 4, *Erysimum Peroffskianum*; 5, *Armeria maritima*; 6, *Papaver Rhaas*.—F. W. C. S. 1, *Campanula Trachelium*; 2, *Sedum rupestre*; 3, S. Ewersii; 4, *Asperula cynanchica*; 5, *Sedum album*; 6, S. reflexum.—J. K. B. 7, not found; 8, *Armeria maritima*, white; 9, *Saxifraga*, one of the mossy-leaved section; 10, *Lotus corniculatus*; 11, *Achillea*, perhaps *tomentosa*; 12, *Saxifraga umbrosa*. Send better specimens next time. Our time is precious.—J. M. K. *Dendrobium Falconeri*, very good varieties.—A. B.—1, *Oncidium pretextum*; 2, *O. crispum*; 3, *O. varicosum*.—E. T. *Odontoglossum Schleiperianum*.—Clarendon. *Epidendrum cochleatum*.—W. J. W. *Stanhopea tigrina*, very dark variety.—R. H. *Dictamnus albus*.

POND WEEDS: E. W. and Gib. The following is the method adopted with success by the Michigan Agricultural College in destroying noxious weeds on a lake in which Lilies, &c., were cultivated. This lake is a ½ of an acre in extent, and the first method employed was that of removing the scum from the surface with a rake and carting it away. After careful experiments it was found that the following formula applied with a spraying-machine, had the desired

effect:—Copper sulphate, 4 lb.; unslaked lime 4 lb.; water, 60 gallons. This effectively destroyed the spores of the various organisms comprising the scum, and in two days the pond was practically clear, the decaying matter having all sunk to the bottom. The entomologist at this College reported that no harm resulted to the fish and frogs by these sprayings, but it would be prudent to confine aquatic birds during the period of treatment. Water-snails would not be of use in keeping the pond free from weeds, though ducks and most aquatic birds are valuable for this purpose.

ROBINIA AT BIARRITZ: C. B. Without seeing a specimen we cannot tell you its name. There are several varieties.

ROSE LEAVES: T. H. S. The eruptions on the Rose leaves are caused by the fungus *Phragmidium subcorticatum*, and those on the Orchid leaves by *Uredo orchidis*. The latter can be destroyed by washing the leaves with a solution of soft-soap.

THE PARKINSON SOCIETY: H. A. H. The Parkinson Society was started in 1884 by Mrs. Ewing in consequence of the interest taken in her story, *Mary's Meadow*. *Aunt Judy's Magazine*, and afterwards *Atalanta*, published occasional reports of the Society, and for a long time the secretary was Miss Alice Sargent, 56, Belsize Park Gardens, N.W. The aims of the Parkinson Society were chiefly the protection of rare British plants, and the interchange among the members of wild and garden specimens and of folk-lore and local names connected with them. Nothing having been lately heard of the Society, we cannot say if it still exists.

TOMATOS: J. D. and J. S. The fruits are attacked with the fungus causing "spot" disease, *Cladosporium lycopersici*. Remove and burn any of the fruits that show sign of the disease. The spores of the fungus are supposed to gain entrance to the fruit through minute cracks or punctures in the skin, therefore the use of green stable manure and of anything likely to induce cracking in the fruits should be avoided. Over-watering has this effect. As a preventive, ventilate freely. Exercise vigilance, and spray the plants with potassium sulphide, prepared as follows:—Dissolve 1 ounce of potassium sulphide in a quart of hot water, then make up to 2½ gallons with cold water, when it is ready for use.—H. B. N., Waltham Cross. Wait patiently; there is no disease.

WALLFLOWERS: A New Reader. Your letter is not very clear. Sow the seeds in pans or boxes at once, and plant the seedlings in their permanent quarters in September, when you say your ground will be available. As to varieties, you can obtain double and single-flowered forms; also varieties varying in colour from buff to scarlet and crimson; tall and dwarf-growing varieties are obtainable, and, if permissible, hybrid forms such as *Cheiranthus × kewensis*. We do not recommend individual firms. Scan our advertising columns. You do not make it plain whether you have to exhibit the Wallflowers as pot plants or as cut flowers. If you have to exhibit them as pot plants we should suppose that the judges will require that the plants shall have been actually grown in them.

YORK GALA: Correspondent. We are now informed that in addition to the plants described in our last issue as having received First-class Certificates at this show, a similar award was made to a variety of *Lobelia* named "Dorothy Dixon," shown by Messrs. E. P. Dixon & Sons, Hull. Mr. Jordan, Impney Hall Gardens, Droitwich, won 1st prizes for a Pine and for Strawberries.

LONDESBOROUGH PARK, MARKET WEIGHTON.

TO many of your readers the name of Londesborough will have a very decided horticultural significance. During the latter half of the nineteenth century it is questionable whether any one of our leading families was more keenly interested in horticulture and allied subjects than were the members of this well-known house. From 1850 till his death in 1860, the first Lord Londesborough planted very largely when extending the park boundaries at Grimstone, near Tadcaster. His name is even yet mentioned with much respect as that of a liberal employer of local labour in this work. The general effect of his work has been seen and admired by hundreds in recent years. He was also keenly interested in gardening under glass, and especially in the growth of hardwooded plants, such as Heaths, Epacris, &c. A special house was erected about 1855 for this purpose, and it is still standing in good condition.

Soon after coming into the title and estates, the second peer began the formation of his well-known collection of Orchids. Probably he was the first amateur who erected houses for their especial culture in Yorkshire. His widow, the present Dowager Lady Londesborough, was also much interested in the culture of plants and

flowers for indoor decoration many years before the practice was so general as it now is. With these thoughts in my mind, when in the Londesborough district recently, I took the opportunity of visiting the gardens there.

I was not in the gardens many minutes before finding out that while time had brought about various changes, there was still much interest shown by both Lord and Lady Londesborough in their gardens generally. The family only resides there during the shooting season, hence the main object is to procure as much produce as is possible in order to supply their requirements when in London or at Scarborough.

There is a large number of home-erected glasshouses, all well adapted for the varying purposes for which they are used. The back range is one of eight vineries, nearly all in full bearing. The first and second ones contain very fine crops of Grapes, mostly of Black Hamburgh, ripe and ripening. Two others are filled with Muscats, and these, too, are fine in crop and bunch, and promise to be excellent in size and colour of berry. In the later houses there is a promise of grand crops, mainly of Gros Colmar, which colours well and is of a much better flavour than is general. I think the fine loam from the calcareous soil at the foot of the Yorkshire wolds may have something to do with this. One house of the variety in question was mainly filled with Vines worked on Black Hamburgh stocks, which Mr. McPherson thought had something to do with improving the flavour.

Peaches, too, are successfully cultivated. The early houses are somewhat different in shape to the general run—viz., three-quarter span, and about 16 feet in width. The front trees are trained on a trellis a little more than quadrangular in shape, as compared with the ones generally seen in old-fashioned Peach-houses. The whole of the back wall from the base upwards is covered with healthy trees, as well as the front trellis. Personally I have a strong liking for three-quarter span-shaped houses for fruit culture, and especially where they are sheltered on the north at a reasonable distance where the shelter will not have the effect of shading the houses. The Peaches in two early houses were Stirling Castle, Royal George, Dymond, Bellegarde, Goshawk, Early Grosse Mignonne, and Violette Hative; all of them had full crops of fruit, fine in size and colour, and the trees were very healthy. Nectarines were equally good, and consisted of Early Rivers, Lord Napier (very fine), and the old Violette Hative, which for colour and quality is hard to beat when seen at its best. Under the ridges there were movable shelves for Strawberry culture, on which there were splendid crops of fruit ripe and to ripen. Royal Sovereign is the favourite variety, though some fine crops of Leader were coming on.

On the south side of the outer kitchen-garden wall there is a Peach case full of fine trees in full bearing. It is nearly a hundred yards in length, and contains twelve trees, which are worth taking some trouble to see. They are trained up a trellis which is about 18 inches from the steeply-pitched roof. There is abundant ventilation both at the top and in the back wall facing north, the air in the latter being obtained from wooden shutters built in the wall. This is a very

important point in erecting narrow Peach cases, otherwise it is difficult to get sufficient ventilation to keep the fruit from ripening prematurely in hot summers. It may be of interest to some readers to mention the varieties that are grown in this case:—Peaches Grosse Mignonne, Royal George, Alexandra Noblesse, Barrington, Nectarine Peach, and Dymond—the harder yellow-fleshed varieties are not cared for, otherwise the season might be prolonged somewhat; Nectarines are represented by Lord Napier, Elruge, Pine-apple, Milton, and Humboldt.

In a large span-roofed house built and once used for plant-culture, I noted a fine lot of healthy pot-trees of Cherries, Plums, Apples, and Pears, all carrying good crops. At the warm end of it were some nice half-standard Orange-trees in full flower. This was a very interesting house. Melons are grown very largely and well. A narrow, slightly sunken, span-roofed house with a path down the centre and a narrow bed on each side was full from end to end with Melons in different stages from those bearing ripe fruit to newly-planted seedlings. The writer considered himself for nearly forty years to be a fairly good Melon-grower, but his conceit has gone now. With the exception of the Melons grown by the late Mr. Wildsmith at Heckfield no others I have seen were equal to the Londesborough ones. Amongst the varieties grown was a seedling raised by Mr. McPherson, which I think will make a name for itself should he offer it to the public.

Like some of his *confrères* Mr. McPherson has found out that to have ripe Tomatos fit for consumption they must be grown parallel to the glass roof that covers them. Fine crops, both ripe and unripe, were in a long lean-to pit with a sunken path against the back wall.

THE PLANT HOUSES.

There are numerous houses full of plants, but, as hinted before, all have to be looked at from the point of view of general utility. Carnations of the Souvenir de la Malmaison type and others for winter flowering were there in abundance. One large span-roofed house filled with fine, healthy plants of the former type presented a grand sight. I was told that as many as one thousand flowers had been cut in one day last year, and could quite see that it could be repeated if needed. Plenty of fresh air, careful watering, and judicious avoidance of excessive feeding supply the reasons why Mr. McPherson, so far as I could discern, is not troubled with Carnation disease in any form. Nearly all the well-known varieties were grown, the old Blush variety and that of Princess of Wales being much liked.

In the large house devoted to Palm-culture were some very nice specimen plants of *Musa Cavendishii*, in 12 and 14-inch pots. I was told that Lady Londesborough made use of this and similar plants for room decoration in the early autumn months. When stood on suitable pedestals in large rooms, no doubt the effect would be very fine. On a large plot covered with ashes, and well sheltered with low hedges, I saw a very fine lot of Chrysanthemums, most of them established in their flowering pots. It was easy to see there was rivalry hatching here for some competitors on the future exhibition-tables of our Northern shows. The collection includes

all the up-to-date varieties, both for the purpose named and for home decoration. This work is mostly looked after by Mr. McPherson's son in his spare time, he having been foreman and general garden helpmeet to his father for some years. Previously he was at Frogmore, Trentham, Croxton Park, &c.

The large kitchen-garden was full of promise for a plentiful supply of vegetables from now onwards to next spring. On the south side of this garden there are some two acres of ground filled with healthy, well-shaped bush and pyramidal Apple, Plum, and Pear-trees, which are a good object-lesson to Northern horticulturists. Notes on these must follow later.

Fortunately, Londesborough is well supplied with water by gravitation, otherwise it would be next to impossible for the very excellent all-round results to be obtained with the limited means at hand. The whole place does great credit to Mr. McPherson, who has been at Londesborough for thirty years, and to his staff. *Yorkshire Gardener.*

NURSERY NOTES.

MESSRS. CARTER'S TRIAL GROUNDS.

At the present time there are no fewer than 1,437 trials of Peas being conducted under equal conditions at Mortlake, and as it were under field culture, farmyard manure being supplied at the rate of 25 tons per acre. The seed was sown on March 30. The earliest variety is one called Carter's Eight-weeks. It grows 1 foot in height, is very productive, and possesses good flavour. Carter's Early Marvel is yet another fine early Pea. This is a seedling from English Wonder and William Hurst. May Flower is only three days behind American Wonder, and has a much better constitution, larger pods, and better-flavoured Peas. This is a seedling from Early Daisy and William Hurst. Many of the individual plants were carrying twenty-two pods of Peas, and there were nine good-sized Peas in a pod. Another fine Pea is Early Stratagem, which is ten days earlier than the old variety, and has fine large pods, and produces a heavy crop. Daffodil is a second early variety, has good pods, is very hardy, and crops heavily. Springtide, a variety with pointed pods, is still prized highly; it quite supersedes William I.

Carter's Superior is a fine Pea, and as early as the variety Lightning. King Edward VII. is a variety of the Early Morn type. It is a fine Pea, of grand constitution and cropping qualities, being one of the best market or garden Peas yet sent out. Early Morn appeared really wonderful, both in size of pod and in its cropping qualities. Torpedo—a cross between Early Morn and Telegraph, was bearing a fine crop of well-finished pods. Time would not permit me to examine closely all the varieties, but these were amongst the most prominent of the seedlings which have yet been named, and of the early-fruited varieties. Later sorts were not at their best.

I was shown a fine new Turnip, a very early white variety, the result of a cross between Milan and Early Snowball, which is earlier than Jersey Lily, and is quite distinct in foliage. It will be a boon, as an early white Turnip was much wanted. I noticed a very fine batch of Canterbury Bells, and a collection of Sweet Peas in 120 varieties.

A trial is being made of forty-six varieties of Wheat. The grass trials for lawn and tennis and golf grounds are also very interesting. *W. A. Cook, Shirley Park Gardens, East Croydon.*

ORCHID NOTES AND GLEANINGS.

EXPERIMENTS WITH ORCHID SEEDLINGS.

M. NOEL BERNARD has been experimenting with certain Orchids with a view of ascertaining the part played in their germination by certain fungoid growths which are discovered in the seedlings. Hybrids of *Bletia*, *Cattleya*, *Cypripedium* and other species made little or no development when an attempt was made to grow them in the laboratory where contact with the fungus was rendered impossible, but upon starting the seedlings in soil infested with fungus a different result was obtained. *Cattleyas*, for instance, in some cases started into growth without the introduction of the fungus, but sooner or later the latter was found to be necessary to their existence. It has been ascertained that the needful "endophytic" fungus is always plentiful in the soil or other surroundings in large Orchid-houses, and this explains why certain hybrids are therein obtained.

further and still more careful trials would yield results by which all growers would benefit.

A fuller account of M. Bernard's experiments will be found in the number of *Le Jardin* for May 20, whence by permission we have extracted the above summary.

THE SEED TRADE.

VEGETABLE SEED CROPS.—The warmer and drier weather of the past six weeks has certainly operated to bring about some improvement in the crops being grown for seed production, though the high winds and tropical showers have beaten down some of the more weakly plants.

Cabbages.—There was perceived early in the year a certain weakness of development in some of the plantations, then came a forcing in time of spring, when the plants appeared to be unable to answer the demand made upon them by Nature; when called upon they made growth

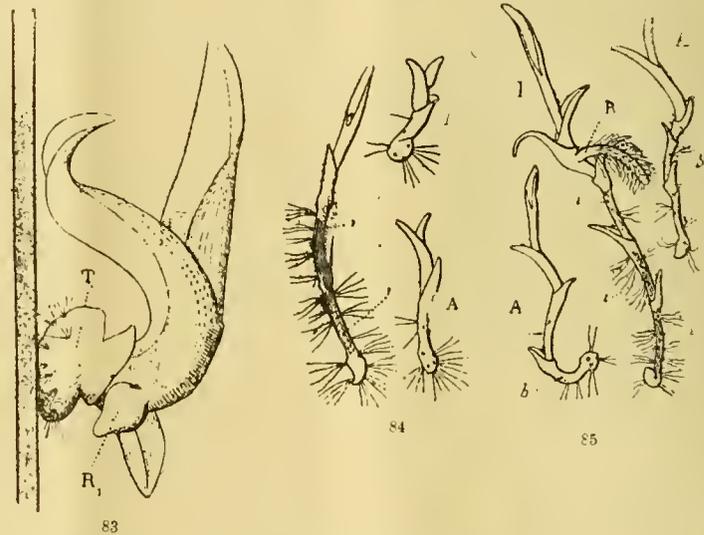

FIG. 9.—EXPERIMENTS WITH SEEDLING ORCHIDS.

- 83.—Plant of *Cattleya* after seven months' culture in a glass tube; T, embryo tuber; R, root.
84.—*Bletia*, aged 3½ months; A, A, after culture without fungus; I, I, after culture with the fungus; I, I, parts infested.
85.—Plants of *Bletia*, aged 5½ months; A, A, cultivated without fungus; I, I, cultivated with fungus; b, b, browned portions; I, I, infested portions; R, root.

Hitherto certain species of *Vanda* and of *Phalenopsis* have not yielded the desired seedlings; at present either the special fungus necessary for these subjects has not been discovered, or the conditions under which they are cultivated prevents that fungus from having access to them. The desired result may be obtained by mixing the new earth in which the seedlings are growing with pieces of the root of an older and infested plant, or even with some of the soil in which that plant is growing. In this manner several seedlings had in five months developed one or two leaves, and were ready to be transplanted, while other seeds sown in the usual way had made no growth. Much time was thus saved by introducing the fungus thus early to the Orchids. In four tubes, three contained seeds of *Cypripedium*, but in the one wherein no fungus had been introduced in three months the seeds had not germinated at all; while in the tubes where the endophyte was present growth was well advanced. The fourth tube contained *Laelio-Cattleya* seedlings growing with the fungus; the latter is not visible to the naked eye, though many growers imagine that they can detect it.

M. Bernard has found considerable difficulty in obtaining fruits of *Odontoglossum* upon which to experiment, and he regrets this, believing that

for a time, then wilted away. There was on the whole less premature bolting to seed in spring-sown Cabbages than is sometimes the case. This tendency is more prevalent on poor land than in soil of good heart. Cabbages are sown for seed purposes at any time between the middle of March and the end of May. The plants which stood the winter for seeding this summer, though much attacked in places by troublesome insects, give promise of a good crop.

Onions.—The unprecedented demand for Onion seeds during the seed season, and the general shortage of the seed crop last year, made it very difficult for orders to be executed. Then Onion-bulbs realised prices very much in advance of their usual average value, and some who had bulbs being held over for planting for seed found it more profitable to sell them on market, especially as there is always a risk in planting Onions for seed. As no seed was carried over and the acreage planted for seed is very small, there is every probability of prices ruling very high in the future. But the foreigner, who has the advantage of a more equable climate, is now growing the finer varieties of English Onions for seeds.

Radishes.—A better time for sowing Radish-seeds was scarcely before known. The seeds

were got into the ground under the most favourable conditions, and yet vermin attacked the plants and practically ruined some of the plantations. There has been, therefore, a great scarcity of salad Radishes in some quarters.

nicely. We seem to be depending for garden culture especially upon the second-early varieties to a greater extent than usual, and a great development can be noticed in the dwarf, dark-green-podded wrinkled Peas; quality and flavour are

and The Gladstone, not to mention others, come into this group. The Gladstone is a Pea of medium growth, green-podded, and of the finest quality, reminding us of what the original Veitch's Perfection was in its palmiest days. It is asserted that this type of Pea gives a quite 50 per cent. of increased yield. Glory of Devon comes into this group; it is a Veitch's Perfection greatly improved. The demand for such Peas is always great, the supply never being equal to the demand.

Beet.—The black aphid has been much in evidence on the plants of Beet for seed; they find their way to them when the plants are in bloom, and seem to suck out their life juices. The outlook as to a probable seed crop is by no means assuring. *Pisum.*

ASTER SUBCERULEUS.*

THIS is the handsome blue-flowered Aster shown by Mr. A. Perry at a recent meeting of the Royal Horticultural Society. It has been confounded with *A. diplostaphioides*, but is quite distinct. The pilose leaves are oblong lanceolate, tapering at the base into a short stalk, and the flower-heads are borne at the ends of the stalk. Each measures when fully expanded 3 inches in diameter. The plant, which is an excellent addition to our gardens, is a native of North-west India, whence it was introduced to gardens by Herr Max Leichtlin. For a botanical description of the plant we may refer to Mr. S. le Marchant Moore's account in our number for November 30, 1901.

COLONIAL NOTES.

TOBAGO.

THE following note is extracted from the *Agricultural News*, the review of the Imperial Department of Agriculture for the W. Indies:—

"The site of a botanic station, to be carried on under the auspices of the Imperial Department of Agriculture, was selected in November, 1898. The station is now fully equipped, is a popular place of resort, with one of the most attractive collections of ornamental plants in the West Indies. In addition, there are maintained large collections of economic plants available for distribution throughout the island. A travelling Agricultural Instructor is employed to afford practical information in regard to the cultivation and the treatment of diseases of Cacao and other crops.

Altogether the prospects of Tobago are brighter than they have been at any time during the last thirty years. It is estimated that there are large stretches of fertile and accessible lands still available for the cultivation of Cacao, Rubber, Cocoa-nuts, fruit, Cotton, Limes, and Tobacco. The absence of destructive hurricanes, the fairly equable rainfall (averaging 65 inches per annum), with the improved means of communication by land and sea, as also the nearness of a large and increasing market in Trinidad for all kinds of produce, render Tobago a promising field for intending settlers."

GREAT STORM IN NATAL.

The *Natal Mercury* for June 9 gives a long account of the great storm which swept over a vast area in Natal on the night of May 31, causing great loss of life and damage to property, whole districts being devastated. Before describing the havoc, the article gives an interesting account of some of the weather reports telegraphed from other districts during the day before the storm. "Pouring rain, with a bitterly cold wind," was mentioned as prevailing at Kimberley; "splen-

* *Aster subceruleus*, S. le Marchant Moore, in *Gardeners' Chronicle*, November 30, 1901, p. 385.

FIG. 10.—ASTER SUBCERULEUS: RAY FLORETS OF BRIGHT MAUVE COLOUR, DISC YELLOW.

Cases are known in which beds were sown, but the plants were so decimated by insect attacks that scarcely a Radish was to be found in a rod of ground. The spell of north-westerly winds which happened worked all the mischief.

Peas.—The early varieties are carrying fair and in not a few cases good average crops, and under the recent dry sunny weather are ripening off

generally excellent; they are of vigorous growth and great croppers. A raiser named Burbidge has done much to increase the type. There are the English Wonder, British Wonder, Witham Wonder, Rivenhall Wonder, &c. The trade is greatly indebted to Burbidge in this respect. Omega may be said to have been the precursor of the section; Gradus, Thomas Laxton, Autocrat,

did rain" had begun to fall in parched Grahams-town; two waterspouts had been observed off the coast at East London; snow was falling in the Orange River Colony; and from several stations in Natal came the news of "rain setting in." Between eight and nine in the evening the storm was raging with great violence, and continued to increase until two hours after midnight, when it gradually abated. "When daylight broke Durban found itself isolated as well as battered by the ravages of the dreadful night."

At South Coast Junction in the Umbilo River valley, where a large proportion of the vegetables sold in Durban are grown, the huts of the Indians and natives, who mostly cultivate garden produce, were swept away by the overflow of the Umhlatuzan and Umbilo rivers, and some 200 of the people drowned, only a few who got caught in the trees escaping. At Bellair Station Mr. Woolridge, a fruit farmer, after anxiously watching until he thought the storm had passed, found his house being washed bodily into the river. With difficulty he freed himself from the wreck, and succeeded in saving his wife. Both were seriously injured, but his two little children were killed. Destruction and disaster are mentioned in many quarters. In Durban in fifteen hours the rainfall was 10½ inches, and at Pinetown over 15 inches. The illustrations show uprooted trees and unroofed houses in Botanic Garden Road, Durban, and other remarkable effects of the storm; also six views of Dundee, Natal, under snow, presenting more the appearance of our British Dundee in winter than views in Natal.

Many singular circumstances are recorded. While Dundee, Glencoe, and the surrounding district were under snow, and had experienced the full violence of the storm, even the telegraph-poles being blown down, Ladysmith and the country around for some distance appeared as an oasis in the desert, the storm not having visited it. Durban was threatened with a stoppage of the water supply, the mains having burst; but the damage was promptly repaired. In other districts gardens and farms were turned into lakes, and great ruin of crops and destruction of cattle is recorded. On the Biggarsberg the snow was 9 inches deep on the levels and 4 to 6 feet in the drifts, and there was great loss of stock.

LEAVES FROM MY CHINESE NOTE-BOOK.

ICHANG TO KAITING.

(Continued from p. 5.)

May 1.—As yesterday was fair, to-day has been foul—one chapter of accidents the whole day through! We made our usual early start, and, assisted by a superabundance of shouting, all went well until we reached the foot of the Lien-Shui-Che rapid at 7.30 A.M. In attempting to tie up in order to carry out a line our tie-rope broke, and we were washed down the river. After a while we managed to get up to the foot of the rapid again. This time we carried out our line safely, and were all but over when a small boat, which, in spite of our remonstrance, insisted in attempting to get over inshore of us, through the breaking of its rope, was washed across our bows. One unfortunate man was dragged in and drowned. We were washed down-stream at a terrific rate, got into several strong whirlpools and were nearly capsized. With the utmost difficulty we got clear of these dangers and managed to haul in our rope. Eventually we managed to get up to the foot of the rapid again, and this time got safely over. On investigating matters, I found two men badly cut and bruised about the legs and shoulders, and totally unfit for work. Several others were suffering from minor cuts and bruises. The tracking-path here being so steep and of sharp rocks, a good foothold was impossible.

The owner of the junk to which the small boat belonged, on seeing the accident, sailed away as rapidly as he could, in spite of the fact that I sent my lifeboat after him. However, the wind was strong and my boat the faster, so we overtook him in a couple of hours and went alongside. I went on board and explained what had happened through the carelessness of his men, and asked what he intended doing in the matter. Chinese-like, he evaded my question, and wanted to chat about the weather. This was annoying, so, cutting him short, I demanded to see his Customs' papers. He was anxious to talk then, but having secured his name and number, I would have none of it, telling him I should report the matter to the magistrate at Wushan city. We had a brother of the deceased on board, and I watched how he bore his grief. Beyond the fact that he was silent and took little or no part in the day's work afterwards, there was nothing to indicate there was anything amiss. The fatal accident upset matters generally, every possible thing going wrong afterwards.

We reached the city of Wushan about 5 o'clock, and I sent in immediately to the magistrate. After stating the case, I requested that justice should be done towards the relatives of the deceased in accordance with Chinese law. The magistrate was very polite and attentive. He pointed out that, strictly speaking, the accident happened outside his jurisdiction, but promised to investigate and do what he could in the matter. In the course of our conversation I gleaned that a tracker's life was fixed at 6,400 cash (about 15s.) and a coffin should the corpse be recovered. It may not be out of place here to relate how the business was settled, though it only came to my ears some months afterwards. The magistrate found the junk owner guilty of culpable negligence, mulcted him to the tune of a hundred thousand cash (about £12), gave the deceased's brother 6,400 cash, and pocketed the balance!

Walking was impossible to-day, and I only noted a couple of fresh plants—*Pittosporum pauciflorum* on the cliffs and *Delphinium anthriscifolium* on the foreshore. On entering the Szechuan part of the gorge, I observed a fine road on the right bank excavated and blasted out of the cliff. At the Lien-Shui-Che rapid, about a hundred yards up the glen on the right bank of the river, *Abutilon sinense* occurs. I found it there in March, 1901, and intended looking for it again had no accident prevented. The plant attains to 5 to 6 feet in height, and its large golden-yellow flowers make it conspicuous. Dr. Henry first discovered it in the Ichang gorge, but my efforts to rediscover it there were futile.

May 2.—We waited till 8 o'clock this morning to see if there were any fresh developments *re* our drowned tracker, but nothing transpired. So leaving the deceased's brother behind to collect the "cash" we continued our journey. The river rose considerably during the night, and the current was very strong. We encountered many rapids to-day, three of them (Sha-ma-Tan, Cho-Tan, and Lung-po-Tan) being severe. The hill-sides of to-day's country were all highly cultivated. The Pulse and Barley crops were ripening fast. In some places the people were busy reaping them. The absence of opium continued most marked. I noted a small patch of *Nicotiana rustica*. This is most unusual, this species being relegated to higher altitudes.

From Ichang upwards I was struck with the enormous quantity of Orange and Pomeloe trees grown. They were everywhere, and I no longer wondered where the quantity comes from which passes through Ichang annually. They are particularly abundant on the more sloping precipices of the gorge. Many of the trees were of large size, and looked very healthy. So far I did not notice the presence of the borer-insect in any of the trees. The Oranges are mostly tight-skinned

and of excellent flavour, but the Pomeloes are too bitter for European palates. Lemons of excellent quality also occur. I enjoyed a nice walk to-day, and gathered several fresh plants. These included *Hypericum sinense*, *Gleichenia dichotoma*, *Premna ligustroides*, *Platycarya strobilacea*, and *Buddleia asiatica*. The last-named is a most charming shrub, with white fragrant flowers. Much to my surprise I came upon one large tree of *Keteleeria Davidiana*. I fancy this solitary specimen must have been planted among some old tombs. Hitherto I have not found it below 1,500 feet alt. On moist grassy banks *Fragaria indica* was plentiful, its tempting-looking but insipid fruit contrasting well with the green grass around. Curiously enough the Chinese consider the fruit poisonous.

I also noticed several Cherry-trees with the fruit colouring. Our old friends, *Sophora viciifolia*, *Rosa laevigata*, and *R. moschata* were still with us, but past their best. We moored for the night just above the Lung-Po-Tan. With but a slight wind we made but little progress against the strong current, but we met with no accident. E. H. W.

(To be continued.)

FORESTRY.

THE LOCUST-TREE.

It is not my intention to enter into a controversy with Mr. Simpson on forestry. I only want to give a precise answer to the question he puts in the *Gardeners' Chronicle* of June 17, 1905, p. 370. At what size, for what purposes, and at what price could Mr. Booth dispose of a thousand acres of Locust-trees? As I remarked on p. 246 of this journal, in Hungary they afforested with great success the sandy plains with this species, after trials with many different trees. A report with all details regarding this enormous plantation, made by a Royal Hungarian Forest Inspector, appeared in a German forest journal in April, 1899. They work this Locust-forest at twenty years' rotation, and do a very large and profitable timber trade. The timber is used for many purposes. What are a thousand acres compared with as many square miles?

I wish I had a thousand acres in Hungary, and another thousand in Germany. In the number for May, 1899, of the above-named journal, reference is made to a report of a Royal Inspector of Coal-mines in Germany. He states that the wood of the Locust-tree is best fitted for carpenters' work in a coal-mine, and also for pit-props. It lasts longer than Oak. The same result has been attained in France. The Inspector closes his report by stating that *Acacia*-wood was rather dear, owing to its scarcity in the market. Is it not a misfortune that the excellent wood of a tree like the Locust-tree, imported more than 200 years ago, growing on the poorest soils and under almost any conditions, is not yet to be had in any quantity? I blame England as much as Germany for this neglect. Almost all the nations display in this respect the same ignorance and indolence, which cost us more, as an enlightened Englishman said, than all the money spent on our education.

A nobleman who has a large plantation on his estate near Berlin, tells me that he sends off waggon-loads of this wood, and sells it well, although single trunks and small quantities do not pay. Many careless calculations and unverified statements are printed, as I see, for instance, on p. 145 of the latest part of the *Transactions of the Royal Scotch Arboricultural Society*, Vol. xviii., where it is stated that "all over Germany there is no coal," whereas we have in truth an enormous part of our population working in coal-mines. So long as this

carelessness continues we shall never progress. It is the same with the school of forestry and the introduction of foreign trees, a question which many of our official foresters consider to be frivolous. So much for the Locust-tree.

Mr. Simpson tells us in the same article that the main obstacle to selling Douglas Fir on the market is that for timber merchants it is simply "Spruce," worth 2d. or 3d. a foot. It is almost twenty years ago that my old friend, the late Mr. McCorquodale, head forester to Lord Mansfield at Scono Palace, cut the first thinnings in a Douglas Fir plantation. This operation gave rise at the time to a good many articles, which

WINCHFIELD LODGE.

Our illustration (fig. 11) gives a view of the residence of Spencer Charrington, Esq. The estate is pleasantly situated at a distance of half-a-mile from Winchfield station on the London and South Western Railway. The house is reached by a short carriage-drive entered from the Odiham and Hartley Row road. About twenty years since the mansion was partly rebuilt and enlarged by the present owner. The grounds are not extensive; they are well sheltered by numerous trees, of which the principal is Oak, which luxuriates at Winchfield. The soil is a heavy loam overlying a clay subsoil. The

Gabrielle Luizet, Sunset, Eugénie Resal, and Magna Charta, besides many others. A specimen of *R. rugosa*, 12 feet in height and 8 feet in diameter, is noteworthy.

Pergolas are here a popular form of garden decoration. Two of these structures run almost parallel to each other, near to the front of the mansion, and must have been made many years ago, judging by the age of the plants with which they are covered. Oak and Chestnut are the woods used for supports. In one case Honeysuckles are almost wholly employed in furnishing the pergola.

Flowering shrubs and trees are freely represented in the grounds. One specimen of *Spiræa*

[From a photograph by F. Mason Good.

FIG. 11.—WINCHFIELD LODGE: VIEW ON THE TERRACE.

appeared in the *Gardeners' Chronicle*, 1887, and in the *Perthshire Constitutional*. "The largest Larch in this plantation measured 12 cubic feet; the largest Douglas Fir of the same age 27 cubic feet. The sale of the thinnings of the Douglas plantation at Taymouth took place on December 23, and they sold at about the same rate as Larch—about 1s. per foot" (*Perthshire Constitutional*, January 11, 1888). I think the main obstacle to the selling of Douglas Fir at the same price as Spruce Fir lies in another direction than Mr. Simpson will have us believe. *John Booth, Corresponding Member of Royal Horticultural Society, Berlin, June, 1905.*

WHITBY JET.—According to the researches of Mr. SEVARD the structure of this substance shows its affinity to wood of the *Araucaria* section.

house is clad with Virginian-Creepers and Roses, of which the latter ramble away very freely owing to the soil being suitable for their growth. On the south-eastern side the varieties Lamarque, Gloire de Dijon, and Reine Marie Henriette fill a large space, and grow to fully 20 feet high.

Roses are greatly favoured by the owner, who has planted them in all sorts of places and conditions, not in any formal arrangement, but just where they would be likely to succeed and produce a desirable effect, such as on pillars, on chains in festoons so as to hide fences, cover banks, as standards in the borders, or dwarf plants in small beds; and indeed they appear to luxuriate everywhere. The best use has been made of such varieties as *Félicité-Perpétue*, *Crimson Rambler*, *Aimée Vibert*, *Leuchstern*, *Penzance Briars*, *Splendens*, *Marie Hoste*, *Madame*

confusa, 10 feet high and nearly as much through, was at the time of my visit laden with its pure white blossoms, presenting a remarkably fine appearance. Many other varieties of this genus are here growing.

Hardy plants are cultivated somewhat extensively at Winchfield Lodge, and include popular kinds of *Narcissus*. Spanish Iris are also extensively grown for supplying flowers for cutting. A remarkably fine bed of seedling *Delphiniums* (*Kelway's strain*) is a grand sight; these are enhanced by plants of *Crimson Rambler Rose* in the centre of the bed.

Mr. Whitworth, the gardener, appears able to grow *Hollyhock* plants for several years in succession. A batch of these plants (*Sutton's seedlings*), planted-out three years ago, have each year given good spikes of flowers, and promise during the

present year to develop half-a-dozen inflorescences from each plant. On the south-west side of the mansion is a remarkably fine croquet lawn, an acre in extent, possibly one of the best in the country. The turf is very firm and the grass close in growth, and reflects much credit on its management.

The kitchen and fruit gardens are not extensive, but they are well managed. A bed of Sutton's April and Flower of Spring Cabbages proved the value of these varieties for yielding an early supply of these vegetables. Peach-trees on walls were carrying good crops of fruit, Waterloo and Rivers' Early York especially. Bush Apple-trees are very promising. *A Wanderer*.

NOTICES OF BOOKS.

THE AMATEUR GARDENER'S ROSE-BOOK, by the late Dr. Julius Hoffmann. Translated from the German by John Weathers. (Longmans, Green & Co.)

This book comes as a surprise, first that British amateurs should be thought to require any addition to the multitude of Rose-books written for their learning, and next that it should be considered desirable for English Rose-growers to be put in possession of a book on this subject made in Germany. Hotter summers, more brilliant light, more evenly distributed rainfall, more severe weather in winter, must all tend to make the German gardener's practice different from our own. But however much details may differ, the general principles of cultivation remain the same. The author's statement that Roses dislike a heavy soil or one that is tenacious or clayey requires some modification, for in this country such a soil, if drained and properly worked, is by no means unpropitious to the growth of Roses.

We do not think our rosarians would care to carry out the manorial details mentioned on p. 18, details more suitable for Chinese than for British gardeners; but the directions for making a compost-heap are very serviceable. The coloured plates, though showing the flowers reduced in size, are better representations of Roses than are usually met with. An alphabetical list of select Roses with short descriptive notes is a useful addition to the book. Some names are not familiar to us, whilst we miss others, such as *Félicité-Perpétue*. The name *Belle Siebrecht* should be cancelled as a useless synonym, at least in this country. A peculiarity about William Allen Richardson, which we have seen year after year, is not mentioned—viz., that the earliest flowers to open are nearly white and all but destitute of the orange-fawn colour which afterwards becomes so conspicuous. There seems to be a public for any work about Roses, so we have no doubt that many will be glad to add this useful book to their collection.

INSECT LIFE.

Mr. F. V. Theobald has published through Messrs. Methuen a second edition of his very serviceable little hand-book bearing the above title. The earlier chapters are devoted to an account of the structure and classification of insects in general. The succeeding ones include a summary account of the several natural orders, with special references to those insects which are of importance from a practical point of view. The gardener is thus provided with an easy means of identifying his enemies, of learning their ways, and of compassing their destruction. A special appendix is devoted to the use of insecticides, and the necessity of acting on the motto "Prevention is better than cure" is duly emphasised. Washes of soft-soap and quassia are highly spoken of for green-fly: 4 to 6 lb. of quassia should be boiled and mixed with

6 to 10 lb. of soft-soap also boiled—the total quantity of water being 100 gallons. This wash should be used in the form of fine spray. The proper method of employing the very poisonous substance, Paris-green, is explained. Arsenate of lead is said to have many advantages over Paris-green, like which it is extremely poisonous. It is made by dissolving separately in water $2\frac{3}{4}$ ounces of acetate of lead and 1 ounce of arsenate of soda. These quantities are sufficient for 10 gallons of water, and when the mixture has been made add 1 lb. of treacle. For wire-worm, applications of nitrate of soda and kainit are recommended. It need hardly be said that these substances are valuable fertilisers. Superphosphates are of little or no value for destroying grubs in the soil.

GREENHOUSES, HOW TO MAKE AND MANAGE THEM.

Mr. W. F. Rowles gives us under this title a sketch of the methods of constructing a greenhouse and its accessories, and then goes on to the means of stocking it by propagation or purchase. Pots and potting next engage attention, then comes a chapter on soils and manures, followed by others on watering, ventilation, shading, tying, training, pruning, forcing and other details of management. All these diverse subjects are so concisely and clearly treated that we can but heartily commend the book to the notice of the amateur, whilst the most expert gardener will find practical hints that will be of use even to him. Messrs. C. Arthur Pearson, Henrietta Street, Covent Garden, are the publishers of this useful little book, the cost of which is only one shilling.

HOW TO MAKE AND MANAGE A GARDEN.

Mr. W. F. Rowles, whose little treatise on the construction and management of greenhouses we have just had occasion to commend, now undertakes a wider flight, and in the little volume above-named tells us how to choose the site of a garden, how to make a vegetable-, a flower-garden, or an orchard, how to deal with paths, borders, rockeries, drains, and this done, how to grow and propagate the plants whose culture may be desired. The book is not only sound as regards practice, but in the sections relating to the formation of flower-beds and bedding-out generally, the author gives evidence of good taste and of a recognition of the beauty of appropriateness. A garden calendar, showing what is to be done in each month, is full of useful practical hints. As a thoroughly practical little book this may confidently be recommended.

EXPERIMENTS WITH PLANTS. By W. J. Osterhout. (Macmillan & Co.)

The object of this little book is not to teach vegetable physiology, but to induce the would-be student to teach himself. The school-boys in Dickens's *Nicholas Nickleby* had first to spell the word "window," and, the task accomplished, they were then directed to go and clean it. This is the method of teaching in favour now, and there can be no doubt that self-gained knowledge of this character is longer retained and is of greater practical value than that which is obtained from books or imparted by a teacher. In the present book a part of the plant is taken—say a seed, and then the questions are asked, such as, What is it? What does it look like? What parts does it consist of? What work does it do; how does it do it? What helps, and what hinders it? The answers to such questions as these are to be supplied, not by the text-book nor by the lecturer, but are, so far as circumstances permit, to be elicited by the pupil himself by means of observation and experiment. In theory this plan is excellent, but in practice, as most teachers and examiners

know, the average beginner requires a little assistance at the start, otherwise he becomes, as it were, stupefied at the mass of detail before him. He does not know what to look for or what to do, and in his helplessness wastes valuable time, or becomes so disheartened that he abandons the task as beyond his powers. The Huxleyan plan, which was only an amplification of the methods of teaching anatomy in the medical schools, was in so far better that the lecturer explained first what was to be looked for, what was to be found out, and what were the best means of compassing these results. The ground having been cleared, the next step was to put the student in the way of confirming, or it may be of refuting, what he had been told by actual examination of the object or by well-devised experiment. For these latter purposes the book before us is excellently adapted. It contains chapters on the awakening of the seed, the work of roots, leaves, stems, flowers, and fruits, the influence of circumstances on the growth of plants, the occurrence of fermentation and decay, and the "making of new kinds of plants" by cross-breeding as exemplified by Burbank's experiments, and by "mutation" as propounded by Professor de Vries and explained in our columns recently. A "mutation" is defined to be the sudden appearance of a variation which comes true from seed, whereas a variation, fostered and protected by the "selection" exercised by the seedsman, aided by the elimination or "roguing" of undesirable competitors, soon runs out or reverts when the protection is withdrawn. Experiments and observations on this subject are clearly of the utmost scientific and practical value, and it is satisfactory to learn that such investigations are in progress in various experimental stations in the United States. The book before us affords an admirable preparation for such and similar experiments, and it is much to be wished that our gardeners, or the more advanced among them at any rate, should be made not merely to read, but to work through it. It is to be desired that some botanist would prepare a companion volume on comparative morphology and on the classification of plants, subjects with which young gardeners of the present day are less well acquainted than were their predecessors.

L'HYBRIDATION DES PLANTES.

Those gardeners interested in the practice of cross-breeding, and to whom the French language offers no impediment, will find in the little volume published by M. Amat, 11, Rue Cassette, Paris, a useful practical treatise. It is written from a gardener's point of view by M. Raphael de Noter, and those amateurs who desire to "try their luck" in this fascinating pursuit will find ample directions and suggestions, which will lead them on to make research in departments of practical science not entering into the scheme of the present volume.

HOW TO KNOW WILD FRUITS. A Guide to Plants when not in flower by means of Fruit and Leaf, by Maude Gridley Peterson. (Macmillan.)

This is a book which, as its title implies, is designed to facilitate the identification of wild plants when the flowers are not available. The plants in question are those native of the North-Eastern States of America. Descriptions of the fruits are given, and analytical tables to help the observer in his search. Unfortunately, by some error in folding or cutting the sheets, the use of this table becomes difficult; but this accident may be confined only to the copy before us. The book is illustrated with characteristic representations of several of the plants mentioned. For practical purposes the fruits are, in spite of the caution not to trust too

implicitly to colour, arranged according to their colour. A glossary is appended, which is more popular than scientific. A student who in an examination should give the following description of the pollen would, we fear, not satisfy the examiner: "Pollen, the anther-borne grains which fertilise the ovule." The definition of a cell "as a structure enclosing a cavity" would prove equally unsatisfactory. We must remember, however, that the purpose of the book is not the instruction of the student, but to prepare the way for those who wish to know the names of certain trees and shrubs selected on account of the attractive appearance of their fruits or seed-vessels. From this point of view the book will be useful as an introduction to more pretentious treatises.

MY GARDEN IN THE CITY OF GARDENS. (John Lane: The Bodley Head, London, and New York.)

This book, sent out without the author's name or pseudonym, is "a memory," and it has illustrations. These pictures of Oudh houses and gardens are a very pleasing feature of the book. As to the letterpress, that furnishes another instance of the manner in which ladies and others, supposedly writing about gardens, introduce pages of digression upon irrelevant subjects. The cultivation of plants is here quite a minor matter, as room is chiefly filled by descriptions of pig-sticking, cookery, the Indian Mutiny, stuffing and mounting birds, gossip, flirtation, polo-ponies, and other topics having no possible connection with a garden.

Such gardening as is effected is, as may be expected, superintended by the writer, not undertaken by her. She admires the "wealth of colour in tree, shrub and creeper. The *Hibiscus mutabilis*, 20 feet high, covers itself all over with large pink-and-white blooms, exactly like paper flowers! The *Bauhinia acuminata* is graceful, with its pendulous branches of pointed, divided leaves, with their large, loose panicles of whitish and pale pink. The *Buddleias* with their orange bells are rampant. So are the *Lantanas*. About the stone pillars of the verandah are clambering the *béla béla* Jasmine, the white-flowered *Bona Nox* or Evening Glory *Ipomœa*, the *l. grandiflora* and the *Passiflora cœrulea* (the handsome blue Passion-flower), the scarlet Cypress Vine (*Quamoclit*), the Star *Ipomœa (coccinea)* (a blaze of scarlet), the lilac Railway Creeper (*pulchella*), and the blue-and-white *limbata*," whatever they may be.

We have several such descriptions, appreciative and popular though somewhat unscientific, of the flowers found near the author's residence. As an account of nine months in a plain station the book should be acceptable, as it is pleasantly if discursively written. It appears to have been originally a diary or series of letters, and to have been re-arranged for the purposes of publication.

BULBS.

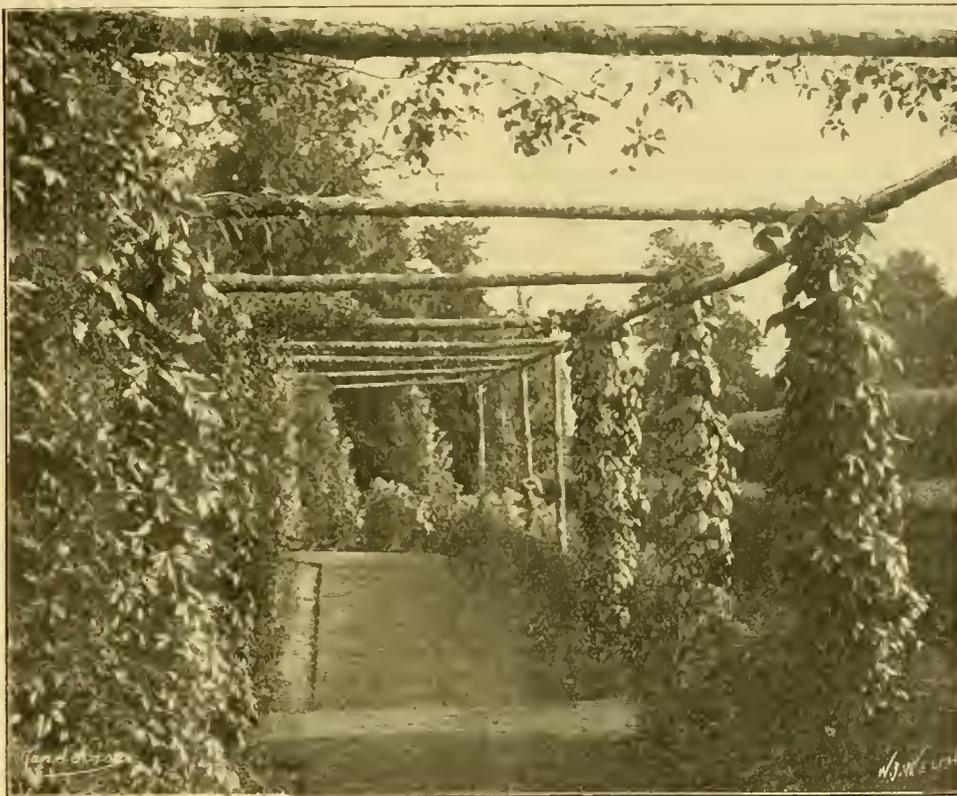

M. Raphael de Noter has published a useful little book entitled *Monographie Horticole des Plantes bulbeuses*, &c. The word bulb is used in a widely comprehensive sense to include most of the *Liliaceæ*, *Amaryllidaceæ*, and *Iridaceæ* commonly cultivated in European gardens, as well as *Cyclamens*, *Oxalis*, and various other bulb or tuber-forming genera. Short descriptions, accompanied in many cases by illustrations, are given of the several species, together with useful cultural notes. In a preliminary chapter the author gives a concise statement as to the culture of these plants in various European countries, but, strangely enough, he omits all mention of Ireland. Had he visited that country, or seen the fine collections of Tulips and Narcissus annually exhibited in London and other centres, he would, we are sure, have avoided this injustice to the neighbouring island. The book is published by M. Charles Amat, 11, Rue Cassette, Paris.

PERGOLA AT SWANMORE.

The illustration at fig. 12 represents a portion of a pergola in the gardens here, made some six years ago. Ivies were used because they afford a varied and pleasing effect, especially during the winter months. This point of view is too often lost sight of in planting these fashionable structures; everybody seems to require a rich summer effect only. This is quite right where absence from home during the autumn and winter is enforced, but to those who see much of their garden during early autumn and throughout the winter, winter effects are valuable.

This was the first pergola formed in this neighbourhood; it was made with stout Larch-poles grown on the estate, planted twenty-five years ago, so that in this detail even this

furnished with Ivy, "dentata," which is especially suited for this purpose; the leaves are large and pendent in habit, and give a bold appearance to the entrance, between which this is formed. This pergola is built on three sides of a square; inside the latter is a Rose garden on grass, sunken 2 feet from the base of the pergola. As previously noted the entrance is between the pair of Ivy-clad pillars; the pergola runs at right-angles from the entrance so far, then branches off at the two corners furnishing both sides of the Rose garden. A variety of subjects is employed for covering the structure, one of the most effective being the old Virginian-creeper, the trails of which hang gracefully down, and when coloured in the autumn the foliage has a rich effect. Quite in the foreground is a thickly clad pillar of the common Hop, which for extra quick

[From a photograph by F. Mason Good.]

FIG. 12.—PERGOLA OF IVY AT SWANMORE PARK.

pergola is interesting. The space from one post to the other, and the width of the path, which is grass, is 8 feet. It is 8 feet high.

In various gardens I have since noted other measurements, and have come to the conclusion that for all practical purposes, such as viewing the plants that adorn the structure, convenience in attending to them, and the welfare of plants growing underneath, 8 feet intervals and 8 feet in height meet the general requirements. Of course, in larger structures built for different objects, such as hiding objectionable buildings in the distance, greater height, width, and solidity are imperative. Pergolas when carefully constructed fill most effectively this object.

Lord Battersea, in his garden at Overstrand, has well illustrated the value of pergolas for hiding objects in the distance. As far as I can see, a plainly-built pergola, whether of wood, brick, or stone, answers the same purpose as an elaborate and expensive structure, because the object is to cover the pergola as quickly as possible by quick-growing plants.

The pair of pillars seen in the foreground are

growth is unsurpassed. Then there are such subjects as *Vitis Thunbergii*, which is here much superior to *V. Coignetiae*; *Actinidia arguta*, with its rich golden-coloured leaves in the autumn, is a superior plant; *Aristolochia Siphis* is one of the best summer and autumn plants, having bold foliage and making quick growth; *Lonicera aureo-reticulata*, with its golden, spray-like growths hanging loosely down, is effective, and most useful for covering the stems of Roses on the pillars which have become bare of growth. *Clematis Kermesiana*, having small claret-coloured flowers, is especially effective as a late and free-flowering variety, and the effect is the greater when planted close to Paul's single white Rose. Roses, of course, predominate in furnishing the arches, such free-flowering sorts as *Félicité-Perpétue*, which is quite one of the best, *Euphrosyne*, the earliest to open, and other varieties include *Dorothy Perkins*, *Wichuriana* varieties, *Crimson Rambler*, *Queen Alexandra*, *Thalia*, *Polyantha grandiflora*, *P. simplex*, *Psyche*, *Claire Jacquier*, *Brunonis*, *Bouquet d'Or*, &c. *E. Molyneux*.

KEW NOTES.

MEGACLINUM PLATYRHACHIS, *Kolfe*.—A species that was sent to Kew from Zomba, British Central Africa, in 1899, and flowered for the first time under cultivation in July, 1903, is now again in flower in the warm Orchid-house. Of all the wonderful forms of inflorescence in the Orchidaceae, none is more extraordinary than that produced by this plant, as is well shown by the figure in the *Botanical Magazine*, t. 7946. The pseudo-bulbs are much like those of a *Bulbophyllum*, and are 2 to 3 inches in length, with two oblong, leathery leaves, varying in length from 4 to 6 inches. The inflorescence is produced from the base of the pseudo-bulb; it has a terete peduncle 6 inches in length, from the end of which the rhachis is very much flattened, resembling a slender greenish-yellow strap, with the small flowers arranged in a row down either side and facing the rhachis. This remarkable inflorescence continues to grow for nearly three months at the apex, at which point the fresh flowers are produced as the old ones fade away at the base. The rhachis ultimately attains a length of from a foot to 15 inches, and is about $1\frac{1}{2}$ inch in breadth. *W. H.*

LINDENIA RIVALIS, *Benth.* (see illustration in *Gardeners' Chronicle*, August 6, 1881, p. 181).

This fine old species from Guatemala is now flowering in the stove. It forms a compact bush with woody growths and opposite, lanceolate leaves from 4 to 6 inches in length. The flowers are terminal and usually solitary. The corolla-tube is 6 inches in length, of a light red colour. The limb of the corolla is pure white, and measures 3 inches across. It is easily propagated from cuttings inserted over considerable bottom-heat. They should be grown on under stove conditions in a light, rich, loamy compost.

GLORIOSA CARSONI, *Baker*.

This very beautiful species flowered in the stove at Kew in July of last year for the first time under cultivation (see *Gardeners' Chronicle* for August 20, p. 127, 1904). It is now flowering profusely in the same house again. It has a strong growth some 6 feet in length, terminated by several flowering branches. The flowers have a diameter of 4 inches, the colour of which is brownish-red, each segment having a margin of golden-yellow. It was collected three years ago about 50 miles south of Lake Tanganyika. *W. H.*

TREES AND SHRUBS.

PYRUS JAPONICA AS A HEDGE PLANT.

It cannot be said that the ordinary method of planting this Japanese *Pyrus*, which is that of putting a plant here and there in the shrubberies, or placing an odd one to grow against a wall, is the best method of illustrating its beauty as a flowering plant. Some years since I collected what plants there were from the shrubberies, and arranged them on each side of a path near an entrance to the kitchen garden here, intending to treat them as a hedge on each side of the path. The plants were topped occasionally during the summer, and the side-shoots were repeatedly pinched, until now the hedges are 8 feet high and nearly a yard through. The growth on the top is quite vigorous, and with that it is intended to form an arch over the path connecting the two hedges together. For the last two months the hedges have been one mass of blossom, the deep scarlet colour having a gorgeous effect. In no other form of training can this plant display its beauty better. It is quite optional how high such a hedge shall grow; anything between 4 feet and 8 feet will suffice. Stout plants put out 2 feet apart in deeply-trenched, well-manured soil quickly attain to a desirable height, and should be

topped occasionally to induce a thickly-grown base. When the desired height is attained much summer pruning of the young growth should be done to induce the formation of spurs as thickly as possible over the whole of the hedge, as from these a yearly crop of blossom is assured. There is no reason why other varieties of *Pyrus*, especially the white-flowered form, should not be treated in a similar way.

THE DOUBLE-FLOWERED KERRIA JAPONICA AS A WALL-PLANT.

Although this Japanese plant is usually seen growing as a bush in the shrubberies, where it flowers grandly in April, it is even better when growing at the foot of a wall having a northern aspect. There being so few flowering plants that are suitable for that aspect, such walls are usually covered with evergreens, of which Ivy predominates. This *Kerria* covers thickly the whole of the northern side of a cottage here, and it is a sight worth going some distance to see. As a rule plants growing in the shrubbery are untidy, the shoots becoming all sorts of lengths and the leaves being generally pale in colour. On the northern aspect the foliage is quite green, which enhances the appearance of the deep orange-coloured blossoms. Now that the plants in question have filled their allotted space they are closely pruned every year after the flowering season with the garden shears. The plant then makes fresh and vigorous growth, which is made secure to the wall, and in the following spring produces a full crop of handsome flowers. Should this plant be growing in a dry situation it will require an abundance of water applied to the roots during the summer. *E. Molyneux, Swanmore, Bishop's Waltham.*

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

*Oncidium*s of the Cool-growing Section, many of which are now resting, need very careful treatment at this period. *O. concolor*, *O. crispum*, *O. Gardnerianum*, *O. Marshallianum*, *O. Mantini* and others that have recently flowered need a very cool, well-ventilated atmosphere during the remainder of the summer. They should occupy a position in the cool-house where the sprayer is not used, and the rooting medium should remain dry until slight shrivelling appears in the younger pseudo-bulbs, when a good watering should be given. Shrivelling caused through flower production cannot be remedied immediately by watering, and the attempt to do so should be avoided, or worse results may follow. *O. Forbesii*, now sending up its floral scapes, should be kept moderately moist at the base. *O. varicosum* is growing, and must be well supplied with water when rooting freely, and as the plants should be near the ventilators the free circulation of air needed induces rapid evaporation, thus necessitating frequent waterings. *O. cheiroporum* also needs liberal applications of water now it is growing freely. Plants of this species should not be exposed to draughts, though fresh air is essential. *O. cucullatum* and its varieties are also growing, and should have water afforded whenever the materials show signs of drying. These may be placed in a lighter position than is suitable for most of the others, associating well in this respect with *Odontoglossum Rossii*. *Oncidium incurvum* grows well in a light position in the *Odontoglossum*-house, and requires an abundance of water during the growing season. The inflorescences are a long time developing, but as soon as they have been removed a thorough rest should be given the plant by withholding water for long periods. Those of the *O. macranthum* group require a plentiful supply of water throughout the summer, regulating the quantity in each case according to the condition of the individual.

It is not desirable to withhold water from these plants for a lengthened period, but the supply should be least during the winter, and at such times as little or no growth is in progress.

Seasonable Work.—Soon after the *Thunias* have passed the flowering stage, the plants should be placed in full sunshine. A sunny sheltered spot outside may be found for them, but before placing them there they should undergo a slight preparation, or the leaves may get scorched. Afford the plants an abundance of water until the leaves begin to fall away, and to keep the latter clean syringe them well on all favourable occasions. Do not allow the deciduous *Calanthes* to suffer from want of water at the base, and should the soil be well filled with roots, apply a light top-dressing of pure fibrous loam. Chemical manures must not be used if permanent good results are desired, but when the pseudo-bulbs are filling up, a little weak liquid farmyard-manure may be afforded advantageously. Apply light fumigations if insect pests are feared, remembering, however, that the less this is performed the better it will be for the leaves, providing thrips can be kept away by other means. Fumigations in all the houses should be done rather frequently, deferring the operation until late in the evening, when the sun has lost its power, and shading the plants earlier than usual on the following morning that harm to the foliage may not follow. It is also a good practice to spray the plants once a week with a mild solution of the N.L.-All, sold for the purpose, doing this early in the afternoon so that most of the liquid will have evaporated by nightfall. This is the only safe and effectual method of ridding *Cattleyas* and allied genera of the troublesome scale which infests the rhizomatous portions of the plants.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Carnations.—Pay frequent attention to the tying-up of flower-stems of the border varieties. Take advantage of showery weather to apply a dressing of soot to the beds, or if dry weather occurs afford water abundantly.

Hollyhocks.—The present is the time to propagate these if it is desired to increase the stock of any choice varieties. Cut the small shoots found at the base of the plants into short lengths, with a bud to each. Insert them firmly in sandy soil in a frame. Keep the atmosphere close, and shade the plants from strong sunshine until they have made roots, then gradually inure them to normal conditions and pot them singly. They will soon make sturdy plants.

Eryngiums are now developing their flower-spikes, and should be afforded neat stakes to prevent them suffering damage from winds, also to improve their appearance by spreading-out the growths to make the most of the beautiful steely-blue involucres, and stems of such kinds as *E. Oliverianum*, *E. alpinum*, &c., and the silvery-white of *E. giganteum*. *E. bromeliæfolium* and others of the *Pandanus*-leaved group are useful for affording attractive foliage.

Rudbeckia "Golden Glow" is an effective plant for the back row in large borders, and associates well with shrubs having purple leaves. The plants will require stout stakes, as will also *Helenium grandicephalum aurantiacum*.

Aquatic and Waterside Plants.—Do not allow the slow-growing species to become smothered by those of quicker growth. Amongst many kinds the following are good:—*Butomus umbellatus*, *Cyperus longus*; *Glyceria aquatica spectabilis variegata* is a pretty variegated grass. The green variety is a rapid grower, only fit for the roughest places. *Mimulus Brilliant* is very bright, and does well in the bog. *Polygonum amplexicanle* and *P. a. oxyphyllum* are useful plants. *P. amphibium* is suitable for the margin of streams. *P. sphaerostachyon* has bright crimson flowers 9 to 12 inches high, and is the gem of this genus.

Shrubbery.—*Spiraea arisefolia* is now at its best, especially where the plant has plenty of moisture and space to develop perfectly; it is a very graceful decorative plant. *S. Douglasi* is of a

more erect habit, and succeeds by the side of a stream, where its dense red flowers are very effective. *S. callosa rubra* is a fine variety. *S. japonica* "Anthony Waterer" is a specially good variety; its deep rose-pink corymbs keep their colour in strong sunshine. *Neillia* (*Spiræa*) *opulifolia* is conspicuous with its feathery clusters of white flowers. *N. opulifolia aurea* makes a bright display at the present time with its golden-coloured foliage.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Peas.—Every effort should be made to prolong the season of this favourite vegetable. Make still another sowing of Autocrat, the best of all late Peas, as with favourable weather they may yield some supplies in autumn. Sow also some of the favourite early dwarf varieties, such as Carter's Little Marvel, May Flower, and Daffodil, all of which have done well here this summer. For affording late supplies I have sometimes been successful with Early Giant and Sutton's Duchess of York, varieties growing from 3 to 4 feet high.

Cauliflowers.—Continue to plant out such varieties as Autumn Giant and Self-Protecting Broccoli as plants become fit for this purpose. These varieties, if given proper attention, will furnish a constant supply up to the end of the year. At the same time it is well to keep up successional batches of the smaller-growing varieties, such as Extra Early First Crop, Early London, and Walcheren, from which a succession of milk-white, medium-sized heads will be assured.

Savoy.—Make successional batches of the variety Dwarf Curled. It is medium in size, excellent in quality and appearance. Plant at distances of 18 inches each way.

Onions raised from seeds sown early in the season are in a somewhat advanced condition. Keep a sharp look-out for mildew, and upon its first appearance use sulphur freely, in sufficient quantities to cover each plant with the powder. When the bulbs are in process of forming apply frequent applications of liquid-manure, occasional dustings of soot, and some approved fertiliser, keeping them well supplied with water. The general Onion crop, which to all appearance requires thinning, may with advantage be allowed to remain in that condition, experience having shown that the results may be expected to be satisfactory.

Mushrooms.—This is not an ideal season for the production of Mushrooms, yet beds carefully made up with well-prepared material in a cool position, preferably under an open shed behind a wall with north aspect, should afford supplies through September. In order to keep the spawn moving as long as possible, the beds should be made of good substance. Insert the spawn when the temperature of the bed is 80°, and cover the surface with about 1 inch deep of loam. In order to retain the moisture in the bed as long as possible, cover it with straw and mats, which should occasionally be damped to lessen the need for applying water to the beds.

General Work.—Shallots and Garlic may now be pulled, and if the weather is fine be left on the ground to dry; otherwise put glass frames over them. When the flowers of herbs begin to show colour they should be cut, tied into bunches, and dried in an open shed.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Figs.—Trees which are now swelling the second crop of fruit should have been freely thinned, as was advised in a previous Calendar. They will now well repay the most liberal culture that can be given them, including frequent applications of diluted liquid-manure, and rich top-dressings of loam and half-decayed manure. Do not allow the third crop of fruits to remain on the trees, but remove them as soon as they can be seen, and so allow the trees to have a proper season of rest before forcing again commences. Thoroughly cleanse the trees of red-spider or other insects as

soon as they have been cleared of fruit. Syringe them frequently and afford copious root-waterings. Any trees that require to be shifted into larger pots or tubs should be attended to as soon as the second crop of fruit has been gathered, as the roots then will be in an active condition, and will soon enter the new soil. Overpotting should be guarded against. Trees that are of full size and are in a healthy and fruitful condition need not be moved oftener than once in two or three years. Good drainage is essential. Pot the trees firmly, using good turfy loam and lime-rubble, with a free sprinkling of bone-meal.

Succession Figs.—Trees in houses which are now supplying ripe fruits will need a slightly drier atmosphere with liberal ventilation to prevent the fruits cracking. Overhead syringing must be discontinued, but a moist atmosphere should be maintained by frequently damping the available surfaces in the house. No fire-heat will be necessary through the day, but if a little be employed at night, with ventilation, it will improve the quality of the fruit. If intended for home consumption each Fig should be allowed to hang until quite ripe, but those intended for packing need to be gathered when dry a day or two before they would ripen perfectly. Later trees, which only supply one crop of fruit in the season, should have all weak growths removed, but the shoots should not be pinched. With frequent syringings and liberal treatment in mulching and feeding, these trees will mature a very heavy crop of fruit. In cool-houses it will be necessary to guard against having too much moisture during unsettled weather when the fruits approach maturity.

Pol Vines.—Pinch out the points of the shoots as soon as they attain to the required length, and take great care to preserve the principal leaves in order that the buds may develop perfectly. The canes will soon show signs of ripening, but continue to use the syringe, and apply manures. Gradually increase the ventilation, especially at night. Unless the house can be fully ventilated, or the top lights removed, the Vines should be placed outside against a wall having a south or west aspect to "ripen."

Planting Vines.—It is not yet too late to replant an early vineyard that has not produced so good a crop of Grapes as could be desired. The house should be thoroughly cleansed, and the border made as recommended in the Calendar for April 29. Choose Vines raised from eyes this spring, and otherwise treat them as recommended in the Calendar named above. Much better canes will then be produced next year than would be obtained from Vines planted next spring.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Souvenir de la Malmaison Carnations.—Now that the season of flowering in the case of most varieties is past, those plants it is intended to grow on for another season should be repotted without loss of time. A careful selection of the best and most vigorous plants should be made for this purpose. A suitable compost is one consisting of three parts fibrous loam, pulled to pieces by hand, and one part leaf-mould or spent Mushroom-bed soil, adding to this a liberal dash of silver sand and a little broken charcoal. Before using the soil let an examination be made for wire-worms, any traces of which should be exterminated, as this pest is particularly partial to Carnations, and would quickly destroy them. In potting make the soil reasonably firm by using a suitable potting-stick, after which the plants will require to be staked. This is an operation that requires to be done thoroughly, using Bamboo-canes to support each shoot. Let this work be pushed forward until completed. Damp the stages and floors of the houses containing the plants frequently during hot and dry weather, and shade them from the sun for a week, but admit a free circulation of air night and day. The process of layering should be continued until the desired number of the different varieties are obtained.

Tree Carnations will require staking, but one stake will be sufficient for each plant, to which the growths may be slung. Continue to stop the stronger growths for a week or two longer in order to induce a bushy habit in plants intended for flowering in late winter, but after this date plants that will flower early in the autumn should not be stopped. Diluted sheep manure may be afforded those plants that are well rooted. In the evening on very hot days syringe the plants overhead with clear water. Upon the appearance of aphids apply a dusting of Tobacco-powder.

General Remarks.—Maintain a tidy appearance in all plant-houses by removing dead leaves or flowers. Attend to the tying of Chrysanthemums, &c., daily. Keep a sharp look-out for any appearance of mites on tender plants, particularly on winter-flowering Begonias, *Dædalacanthus parvus*, *Browallia speciosa*, *Torenia Fournieri*, &c., and destroy the insects by means of frequent immersions in Quassia-extract. Assist batches of plants coming into bloom by applying a light dusting of Clay's Fertiliser over the surface of the soil about once a week. Continue the repotting of plants as they become ready for larger pots.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Apricots.—Examine the trees carefully, and expose the fruits to the full sunlight by tying the shoots aside or by the partial removal of leaves which shade them. Insects such as woodlice and earwigs are capable of damaging the fruits long before they are ripe; therefore take pieces of Bean-stalks, or small pots in which a little moss is placed, and hide them amongst the foliage of the tree. These means will serve to catch many of the depredators. A good and perhaps the most effectual system I have adopted is to smear the wall just above the ground-level with some sticky substance, such as paraffin mixed with soft-soap, to stop the insects crawling up the wall. At the same time a greased band must be placed round the tree-stem. The trees will now be making new growths from the points of the shoots which were pinched back some time ago. These secondary shoots should be pinched back to the first leaf. Continue to apply liquid-manure to the roots of the trees at frequent intervals. If the ground is of a porous nature, a top-dressing of half-rotten cow-manure will prove beneficial. In districts where the branches of Apricot-trees are prone to "gum," eventually dying, allow sufficient young shoots to extend for filling up a blank space should it occur; such trees should be well nourished, and only lightly cropped.

Peach-trees on Walls will now require further attention; the shoots should be secured to the wires, or nailed as the case may be, stopping the laterals to one leaf, and cutting out entirely extra-vigorous shoots, stopping those which are moderately so. Shoots having no fruit upon them may be removed, laying-in the current year's growth, thereby giving it an opportunity to mature. Keep the trees free from aphids by an application of Quassia-extract, syringing them afterwards or next day with clear water.

Plums.—If heavy crops are swelling, the clusters may be thinned, and where large fruits are preferred to a greater number of small, undeveloped ones, the thinning must be done liberally. Culinary varieties may be gradually thinned as the fruits reach the size for cooking purposes, finally leaving only such a crop to mature as will not overburden the tree.

Pears.—It can now be determined which fruits are likely to remain on the trees, and where several of a cluster are swelling evenly together, remove some of the least exposed fruits. In doing this take into consideration the natural size of the fruits and the vigour of the individual tree. If the crop is general throughout the tree one or two fruits of such varieties as Pitmaston Duchess or Doyenné du Comice will be sufficient to leave on a spur; smaller-fruited varieties may be cropped rather more numerously. In no case permit such a crop to remain as would seriously lessen the vigour of the tree.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JULY 11	<ul style="list-style-type: none"> Royal Horticultural Society's Summer Exhibition in the Grounds of the Royal Hospital, Chelsea (3 days). Harrow Flower Show. Wolverhampton Floral Fête (3 days). Cambridge Horticultural Show.
WEDNESDAY, JULY 12	<ul style="list-style-type: none"> Reigate Flower Show. Bath Rose and Begonia Show. Nottingham Horticultural and Botanical Society's Exhibition (2 days). Lee and District Flower Show (2 days). Beckenham Rose and Horticultural Show.
THURSDAY, JULY 13	<ul style="list-style-type: none"> Potters Bar and District Amateur Rose Society's Show. Chipping Norton and North Oxon Rose Show.
SATURDAY, JULY 15	<ul style="list-style-type: none"> Kidderminster and District Summer Flower Show.

SALE FOR THE WEEK.

FRIDAY NEXT—*Cattleya Schrödera*, *Dendrobium Findlayanum*, &c. by order of Messrs. Saender & Son; also Imported and Established Orchids from various sources, by Protheroe & Morris, at 67 and 68, Cheapside, E.C. (For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —63°3'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, July 5 (6 P.M.): Max. 74°; Min. 58°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 6 (10 A.M.): Bar., 30.1; Temp., 66°. Weather—Dull, with occasional sunshine.

PROVINCES.—Wednesday, July 5 (6 P.M.): Max. 69°, Guildford; Min. 57°, N.E. Scotland.

Shows of the Week.

THE commodious Hall of the Royal Horticultural Society was, on Tuesday last, filled by Sweet Peas, to the almost complete exclusion of other subjects, the exceptions being such as were submitted for inspection by the various Committees. Change is desirable, no doubt, and on ordinary Tuesdays the long, straight benches become somewhat monotonous to the frequent visitor, who has learnt to know within a little what Messrs. So-and-So are likely to exhibit, and where the groups displayed by Messrs. This-and-That will be found. There could be no doubt as to the elegance, the varied and delicate colouring and the fragrance of the Sweet Peas, but they are deficient in interest as compared with many other flowers. They appeal to the eye rather than to the intelligence, and great as has been the progress in colour and refinement, there is a monotony of form which is apt to engender a sense of indifference, if not of absolute weariness, when Sweet Peas are shown in such vast quantities as they were on Tuesday last. This, perhaps, is the

case, less or more, in all special exhibits of whatever genus, but it was emphasised in this case by the circumstance that all these beautiful forms are derived from one and the same species, and consequently that the range of variation is limited by comparison with that which occurs in most other garden favourites. For purposes of general decoration there is an appearance of weediness which renders them ineffective, although their grace and delicacy of colouring fit them well for dinner-table adornment, as was well illustrated in the numerous tables shown in competition on Tuesday. The judges must have had no little difficulty in coming to a decision as to the relative merits of the exhibits, and where so much depends on individual taste we doubt not that a second set of arbiters would frequently have come to a different conclusion. As tables so decorated are mostly intended to be seen by artificial light, it would be well on another occasion if some at least could be shown in a room illuminated by the electric-light only. The first prize in one class was given to a group consisting of a tasteful arrangement of a variety with pale lavender flowers intermixed with *Asparagus plumosus*, and with trails of the broader-leaved *A. scandens* laid on the cloth.

There were endless differences in shades of colour in the general collections, but not much actual novelty, the variety attracting most attention being "Helen Lewis," as shown by a private exhibitor, Mr. WATSON, from the gardens at Orford House, Ham Common. This is a beautiful variety with large flowers of a salmon-pink colour with a suspicion of orange, fading off into pale yellow, the colour of the standard being distinct from that of the wings. Such a combination of colours cannot be adequately shown in black-and-white, but its form and general appearance are illustrated in Mr. WORTHINGTON SMITH'S drawing in another column (fig. 15, p. 35).

As we have intimated, exhibits other than Sweet Peas were rare, and some of greater intrinsic interest, as many might think, certainly of greater novelty, were we know excluded. On another occasion this boycotting policy might well be modified without prejudice to the Sweet Peas. From what we learn, however, there must have been some misunderstanding, for although "groups" were excluded, new plants and plants for certificate were invited, and, as our report shows, some were exhibited.

Another event of the week consisted in the great display of Roses made in the grounds of the Royal Botanic Society, Regent's Park, as these pages were passing through the press. The National Rose Society's Metropolitan exhibitions were wont to be held at the Crystal Palace, and for the last four years in the gardens of the Inner Temple. Circumstances have prevented the Society from availing itself this year of either of these localities. The beautiful gardens of the Royal Botanic are well adapted for an exhibition of this kind, and we doubt not that if the weather continues as fine as at the time of writing the success of the show will be assured, and that the Society will not suffer from its enforced migration. In another column we shall give as full a report as the time at our disposal will permit.

CLEMATIS ARMANDI* (see Supplementary Illustration).—This is a new hardy evergreen species first discovered in 1869 by PÈRE DAVID in the principality of Mu-piu, Western China. It was described and figured by FRANCHET in his *Plantæ Davidianæ*, ii., t. 2. Subsequently Dr. HENRY, and later Mr. E. H. WILSON, rediscovered it in the mountains of Hupeh, Central China, the latter of whom in 1900 sent seeds to Messrs. JAS. VEITCH & SONS. Plants raised from these seeds flowered for the first time in Messrs. VEITCH'S Coombe Wood Nursery in the spring of this year. This species is of rapid growth, and is one of the earliest of all to flower. So far it has proved perfectly hardy, retaining its foliage all through the winter and on into the late summer, its evergreen character making the species unique amongst hardy Clematis. The leaves are three-foliolate (ternate), very coriaceous; leaflets oblong or oval, 6 inches by 2½ inches, acuminate, sometimes slightly cordate at the base, prominently three-nerved, reticulate, glabrous save when very young. The flowers are borne on the old growths in axillary cymose clusters. The individual cymes are three to many-flowered. The flowers are white, often rosy-pink on the back, 2½ inches in diameter, fragrant, pubescent on the underside, with six to eight or only four petals. The bracts subtending the pedicels and cymes are pubescent, and so also are the very young shoots. Some botanists consider Clematis Armandi to be a variety of the polymorphic *C. Meyeriana*, *Botanical Magazine*, t. 7897; but Messrs. FINET and GAONEPAIN, the latest monographers of the genus, agree with FRANCHET in considering it a good species, and certainly Mr. WILSON'S specimens are very different in the inflorescence. However, let its botanical affinity be as it may, for horticultural purposes it is abundantly distinct. Clematis Meyeriana has smaller white flowers, and usually pinnately five-foliolate leaves. It is relegated to the warmer parts of the Yangtze Valley and China generally, where a warm temperature and sub-tropical climate obtain. Clematis Armandi, on the contrary, occurs only on the mountains from 2,000 to 4,000 feet. Its distribution extends from Hupeh, Central China, to the far west of Szechuan (Tibetan border). On scrub-clad mountains it is very common, festooning bushes and rocks. When in flower it presents a picture not easily forgotten. Mr. WILSON tells us that he counted as many as thirty flowers in one axillary cluster. The Chinese name for it is Wei-ling-hsien.

THE ROYAL HORTICULTURAL SOCIETY'S SHOW AT CHELSEA.—The Royal Horticultural Society will hold their summer show, by the kind permission of the Lords Commissioners, on Tuesday, Wednesday and Thursday next, July 11, 12 and 13, in the grounds of the Royal Military Hospital, Chelsea. The ground is ten minutes' walk from Victoria Station and about five minutes from the Sloane Square District Railway Station. The London County Council steamboats are now running, and Chelsea Bridge pier almost adjoins the main entrance. Omnibuses from all parts run along King's Road, Chelsea, which borders the estate on the north side, and Pimlico Road, over the Albert suspension bridge, and to Sloane Square. These directly connect the show with Liverpool Street, the Bank, Fleet Street, Piccadilly, Westminster, Victoria, Islington, Holloway, Shepherd's Bush, Clapham Junction, and most other parts of London. The arrangements will be similar to those made at the shows in the Temple Gardens and to the summer shows hitherto held at Holland House by the Society. The show will be open at 12.30 on July 11 to Fellows of the

* *Clematis Armandi*, Franchet in *Nouv. Arch. du Muséum*, ser. ii., viii. (1865), p. 184; O. Kuntze, *Mon. Clemat.*, p. 152; Finet and Gagnepain, "Contrib. Flor. Asie Orientalis," *Bull. Soc. Bot. France*, Nov. 13, 1903.

CLEMATIS ARMANDI, A CHINESE SPECIES, WITH WHITE OR CREAM-COLOURED FLOWERS.

Society free, and to the general public on payment of 7s. 6d.; on Wednesday, July 12, the charge for admission will be 2s. 6d., and on Thursday, July 13, the price will be 1s. Silver Cups and Medals will be awarded according to merit, and the classification will include Roses, Orchids, fruit, and vegetables, hardy herbaceous and out-doors groups, alpinas, and rock gardens, foliage and flowering plants generally, and there will be a special tent for horticultural sundries and appliances. Lieut. CHAS. GODFREY'S band will play each day, and ample arrangements for refreshments have been made.

FLOWERS IN SEASON.—From Messrs. GAUNTLETT, of Redruth, we have received a consignment of noteworthy flowers in the shape of cut specimens. They are not novelties, but many are of special interest:—

Ozothamnus thyrsoides, which the Kew authorities say should be called *Helichrysum diosmifolium*, is a Composite shrub with linear leaves, on thick-set ascending branches bearing very numerous small white flower-heads. It is a most showy shrub.

Buddleia variabilis is remarkable for its lanceolate leaves, hoary on the under surface, and with long elegant spikes of bluish flowers. It is figured in *Gardeners' Chronicle*, August 20, 1898, p. 139.

Phlomis fruticosa is a very old friend. *Phormium tenax* var. *viridis* is sent in flower, the blooms being of a deep red colour.

Escallonia langleyensis × has pretty rose-coloured flowers. It is cross between *E. macrantha* and *E. Philippiana*. An illustration was given in the *Gardeners' Chronicle*, July 10, 1897, p. 15.

Olearia macrodonta is remarkable for its boldly toothed leaves and showy flower-heads. It was illustrated in the *Gardeners' Chronicle*, Sept. 4, 1886, p. 305.

With these came also some fine varieties of Japanese Irises.

A ROSE SHOW AT THE CRYSTAL PALACE.—For many years the shows of the National Rose Society were associated with the Crystal Palace, and they were so popular that this year the authorities at the Palace have determined to hold one under their own management. At the exhibition, which takes place on Saturday, July 8, a sum of £225 is offered in prizes, and fourteen medals will be awarded for groups.

THE ROATH PARK, CARDIFF.—According to a "Guide," of which a copy is before us, this comprises an area of over 100 acres, divided into six distinct portions intended for use as playing grounds for athletes and for children; pleasure grounds for those who take their pleasure less energetically; and a botanic garden for those who seek interest as well as pleasure and recreation. The catalogue of the plants, arranged in their several natural orders, is very full and evidently very carefully compiled. It gives one an idea of the trouble involved in keeping such a collection properly labelled. In these days, when the study of systematic botany is, we may say, systematically neglected, it is refreshing to see what is done in Cardiff towards remedying this defect. The ordinary gardener has or ought to have much better chances of familiarising himself with the characteristics of the principal natural orders than with the minutiae of what we may call laboratory botany, to which too exclusive attention is paid nowadays. Without wishing to derogate in the slightest degree from the importance of the study of microscopical anatomy and of the physiology of plants, we yet think that for the average practical gardener a knowledge of the conformation of the principal natural orders is of greater immediate value. We note incidentally that a collection of Ferns derived originally from the gardens of the late Mr. E. J. Lowe is to be met with here. Fern-lovers should take note of

this. Lakes, ponds, aquaria, and "wild-gardens" add to the attractions of this park. Lists of the birds and mammals, including the otter, are given, whilst of the rabbit it is said that it is frequently seen, but is not encouraged—a circumstance which does not surprise us. Mr. W. W. PETTIGREW is the Superintendent of the Parks Department, and to him the Cardiff people are under great obligations for the preparation of this useful guide.

AN OBJECT-LESSON.—When, thirty-three years ago, Japan began her new career, there were a few people like ITO clever enough to see and say that the study of ancient classics alone, to the neglect of the study of Nature, meant ruin to the country; but such ideas would never have been adopted had not Japan been in deadly peril. All the nations of Europe bullied and insulted her, and it was only their mutual jealousies which saved her from complete subjugation. In the presence of that peril the pedants held their peace, and everybody saw the necessity for an immediate radical reform. In time Nature was studied by every child in Japan, and in consequence scientific methods of thinking and acting have permeated the whole nation. All ancient and modern European literature is open to the Japanese who know English, and English is the one language other than Japanese which every cultured man must know. In the matter of self-protection everyone can see the result. Because the Japanese have studied Nature their scientific officers and men have marched or sailed to victory in every engagement; their statesmen will do exactly what is best for Japan in the negotiations for peace; their country will quietly take its place as one of the first-class Powers of the world, and every person who knows anything about Japan is quite sure that ambitious, wrong-headed schemes of conquest are altogether impossible to the scientific minds of the Japanese. If Japan had not been in great danger we know that she would not have taken to nature-study, and some of us think that it may need a state of danger in England to produce the necessary desire for reform. The South African muddle was worried through, and almost everybody seems to think that all such muddles may also be worried through, but some of us think that we may not always be so lucky. Danger is close enough even now, and we can only hope that if it becomes great it may grow slowly enough to let us learn something from the object-lesson which is being given us day by day in the news from Russia and the Far East. *John Perry*, in "Nature."

FLOWERS AND INSECTS.—Mlle. JOSEPHINE WÉRY concludes, from some experiments recorded in the *Bulletin* of the Royal Academy of Sciences of Belgium, that the attraction exerted on insects by the form and colouration of flowers is much greater than that exercised by their pollen, their perfume, and their nectar collectively.

HENRY ECKFORD TESTIMONIAL.—The contributions to this Fund up to Saturday evening, July 1, amounted to 836 shillings.

"THE JOURNAL OF ECONOMIC BIOLOGY."—Under this title a new periodical is announced to be published, edited by WALTER E. COLLINGE, Lecturer in Zoology and Comparative Anatomy in the University of Birmingham, with the co-operation of Professor A. H. REGINALD BULLER, the University of Manitoba; ROBERT NEWSTEAD, Liverpool School of Tropical Medicine; Professor GEO. H. CARPENTER, The Royal College of Science, Dublin; and A. E. SHIPLEY, Christ's College, Cambridge. The need of a recognised medium for the publication of original investigations has long been felt by workers in economic biology. No such paper at present exists in this country, and the difficulty of obtaining prompt publica-

tion, with the necessary illustrations of papers of a high standard, is well known. A special feature will be made of the illustrations, and every care will be used to see that the papers are of an equal standard. The Journal will be issued at a prepaid annual subscription of 16s., four parts to the volume, the first of which will appear on September 29. A number of British and foreign biologists have already promised their support, and it is hoped that the Journal will be found in the libraries of all universities, university colleges, schools of agriculture, experiment stations, the public libraries of all large cities, and in the private libraries of zoologists, botanists, entomologists, mycologists, &c. All business and literary communications should be addressed to the editor, and all subscriptions should be forwarded to Messrs. DULAU & Co., 37, Soho Square London, W.

SIR EVERARD IM THURN.—Among the honours published in celebration of the King's birthday we learn that the rank of K.C.M.G. has been conferred upon our correspondent EVERARD FERDINAND IM THURN, Esq., C.M.G., Governor and Commander-in-Chief of the Colony of Fiji, and His Majesty's High Commissioner for the Western Pacific. Previous to his appointment to Fiji, Sir EVERARD held magisterial office in British Guiana, and to him we are indebted for much valuable information on the flora of that Colony and of Roraima, whence he introduced many remarkable Orchids and other plants. Sir EVERARD'S services were largely utilised by the Government in the settlement of boundary questions relating to Venezuela and to British territory. Subsequently he was appointed to Ceylon, so that he has well won the honour now bestowed upon him.

PRESENTATION TO A GLASGOW SEEDSMAN.—On the eve of the marriage of Mr. DANIEL GRANT PURDIE, manager of the firm of Messrs. SMITH & SIMONS, a very representative meeting of the trade gathered in McCULLOUGH'S Restaurant, Maxwell Street, to wish him God-speed. Under the presidency of the senior partner of the firm, Mr. GEORGE DAGO SCOTT, who was supported by the junior partner, Mr. ROBERT SADLER, and Mr. ANDREW CUNNINGHAM (Messrs. CUNNINGHAM & WYLLIE), a very harmonious meeting was held. The toast of the guest of the evening was proposed from the Chair in words of appreciation for services rendered during the past fifteen years to the firm. The presentation consisted of a solid silver tea and coffee service, and in a few feeling remarks Mr. PURDIE acknowledged the fraternal feelings which prompted such a handsome gift on the occasion of his wedding. The toast of the seed trade, proposed by Mr. DRUMMOND CAIRNS, was heartily responded to; and Mr. PETER DREW, of Edinburgh, replied, advocating the holding of a social gathering frequently with a view to the formation of a trade association for instructive purposes, emulating the work already done by kindred associations in Edinburgh and Dublin. This suggestion, needless to say, was heartily supported, and in all probability will be acted upon this year. The Chairman expressed himself in full sympathy with the movement of an association being formed for the improvement of the members.

ACETYLENE LIGHT AS AN AGENT FOR FORCING PLANTS.—The Cornell University Experiment Station has been interested during the past winter in testing the influence of the acetylene light in promoting plant growth. It is a notorious fact that the months of November, December and the fore part of January are trying periods for the greenhouse man. It is at this time that he struggles with the contradictory problem of insufficient light and the necessity of ventilation and watering. During the past

winter experiments have been conducted by M. J. IORNS, a graduate student in the Department of Horticulture at the forcing-houses of Cornell University, having for their purpose a comparison of the influence of acetylene and electric light on plant growth under different temperatures. In a recent number of the *Acetylene Journal* a condensed statement of the gross results obtained are presented. It was found that acetylene light, approximating closely to the quality of the sun's spectrum, exerted an energetic influence on plant growth. Plants grown under acetylene light vegetated much more rapidly than others not under its influence, and those grown for cut flowers reached the blooming stage considerably in advance of their competitors grown under ordinary sunlight only. Easter Lilies grew twice as high and bloomed ten days to two weeks in advance of those outside of the acetylene lighted area. The growth of Radish and Lettuce was greatly hastened, and the yield in a given time much increased. The branches of flowering shrubs responded in a marked degree to the influence of the light. Those under acetylene light bloomed several days in advance of those in the same temperature and influenced by daylight only. It was also proved that the plants under the influence of acetylene light only would form chlorophyll as if grown in sun-light. *The National Nurseryman*.

"**LUCRETIA**" BRAMBLE.—We are indebted to Messrs. ROBERT VEITCH & SON, of Exeter, for a specimen of this white-flowered Bramble. It is attractive when in flower, the blossoms resembling those of small Roses, and it ripens its fruits earlier than the ordinary Blackberry.

SEEDING AND GERMINATION OF MECONOPSIS INTEGRIFOLIA.—Messrs. J. VEITCH & SONS, Chelsea, inform us that they have gathered ripe seed of this plant in their nurseries, Langley and Coombe Wood. Plants have produced fine capsules, as have those exhibited at the various horticultural meetings. The first ripe seed was gathered on June 19, and on June 22 test-sowings were made under various conditions. The seed sown in a cold frame grew best, and commenced germinating on July 4.

CARBONATE OF BARYTA.—The *Revue Horticole* has an article on the use of this substance as a poison for rats, voles, &c. The baryta is used in the proportion of twenty parts to eighty of Wheat flour. Water and yeast are added to form a paste, which is allowed to ferment and then baked so as to form hard cakes. These cakes are steeped in skim milk and then broken up into pieces of the size of a Hazel nut and placed in the "runs," care being taken so to place them as to be out of the way of poultry. Spring and autumn are the best periods at which to operate. The poisonous character of the preparation must always be borne in mind, and the workmen after using it should wash their hands in water to which a little vinegar has been added. This removes all trace of the baryta. The results of experiments in fields infested with rats and voles showed that the poison is very efficacious, and its application less costly than the LÖFFLER virus, which is however more suitable when the number of animals is very large and their distribution widely extended.

RESERVE SUBSTANCES: THE WORK OF DECIDUOUS AND OF EVERGREEN LEAVES.—The differences in the process of nutrition, the formation and storage of starch and other hydrocarbons in deciduous and evergreen shrubs respectively is well illustrated by the researches of a French botanist, M. LECLERC DU SABLON, who in the *Comptes Rendus* for June 13 gave a summary of his experiments concerning the hydrocarbonaceous reserves, starch, sugar, &c., in evergreen and deciduous-leaved plants respectively, and at different seasons of the year. He arrives at the

conclusion that the amount of these substances, which in trees with deciduous leaves is greatest in autumn at the fall of the leaf, in trees with evergreen leaves is greatest in the beginning of spring when the buds are about to open. The minimum amount which is observed in May in trees that lose their leaves, is found in July or August in the case of evergreens. These differences are easily explained by the fact that in evergreen leaves assimilation takes place all the year round, but in relatively weak intensity; while in the deciduous leaves assimilation is only carried on from May to October, but then more energetically.

FIG. 13.—ROSE WALTHAM BRIDE.
A summer-flowering hybrid of the multiflora type, with pure white flowers, exhibited by Messrs. Wm. Paul & Son.

PUBLICATIONS RECEIVED.—*Notices sur les Plantes Utiles ou Intéressantes de la Flore du Congo*, Emile de Wildeman, Conservateur au Jardin Botanique de l'Etat, Bruxelles, iii.—*Jahresbericht der Bayerischen Gartenbaugesellschaft* (Year-Book of the Bavarian Horticultural Society), 1904, Munich.—*Bolctim da Sociedade Brotteriana*, J. A. Henriques, 1903, Coimbra. This Bulletin is chiefly devoted to a description of the grasses of Portugal (written in Portuguese) by Senor J. A. Henriques. Imperial Department of Agricultural for the West Indies: *Cultivation of Oranges in Dominica*, by Mr. Hesketh Bell.—*Twenty-fifth Annual Register of the Officers and Students of the Colorado State College of Agriculture and the Mechanical Arts*, an illustrated compendium relating to the above-mentioned College. "Botany, structural and systematic, is taught from text-books and by lectures. A great variety of plants is at hand. In physiological botany the students use compound microscopes and have laboratory practice two hours daily. An herbarium of native and foreign plants and the greenhouses furnish material for study. Instruction in horticulture is given principally by means of lectures. Some of the subjects considered are vegetable gardening, methods of plant propagation, forestry, pomology, floriculture and landscape-gardening."—*Annual Administration Report of the Forest Department of the Madras Presidency*, to June 30, 1904. "The year's administration as a whole may be considered as one of satisfactory progress."

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

SWEET PEAS.—As in the case of thousands of cultivators like myself, I cannot doubt the Sweet Pea was the favourite flower of their boyhood; in the light of its development and intensified attractiveness, it can hardly fail, under such exquisite conditions, to remain the chief abiding floral fascination of their maturer years. Some of our grandest Roses do not open with facility, are wanting in fragrance or artistic formation; the Sweet Pea is almost infallible in those respects. Nor is this queen of all annuals so susceptible as many other flowers of greater splendour and impressiveness, to atmospheric influences. One of its most recently originated crosses, indeed, entitled "The Scarlet Gem," seems (from its raiser's indication of its one sole liability or serious limitation) to be an exception to the prevailing rule; it can be, like Hamlet, Prince of Denmark, a remarkable cross introduced by Shakespeare, "too much in the sun." In other words its sensitive nature demands congenial shade, which it finds in my garden, where, during last season, grown up venerable Apple-trees in charming association with Sadie Burpee, Dorothy Eckford (the grandest of all pure white introductions), and Lady Nina Balfour, its effect was very memorable. Another Sweet Pea of recent origination which, while almost equally brilliant, is in the direction of conservation of colour under exacting solar conditions greatly more reliable, is the already far-famed King Edward VII, the brightest and most effective of all the finest existing crimson-coloured varieties. It is a grand grower, and its luminous flowers expand with splendid facility. Gladys Unwin is another remarkable acquisition raised by Mr. Unwin at Histon, Cambridge, generally characterised by competent cultivators as a distinct advance on Countess Spencer. This is a variety which has achieved a very remarkable popularity in virtue of attributes of growth, formation and distinctive colour which it will be difficult for future hybridists to transcend. Other recent creations or introductions of great merit and widely varying hues and characteristics are Bolton's Pink (one of the loveliest of its section), John Ingman and Marchioness of Cholmondeley, Florence Molyneux and Zenie Cuthbertson, in whose success, for various reasons, I am interested. Henry Eckford, Black Michael, and Romolo Piazzani I have not yet seen; but in their merits and those of my Eckfordian namesake I believe. *David R. Williamson*.

GARDEN WALKS.—The formation of my garden paths at this place cost me very little, either in labour or expense. The ground, to begin with, was pasture land, intersected with several hedgerows, which were cleared away. In breaking up that portion of it which I intended for cultivation I simply marked out the spots where paths were wanted, and left the grass which now forms the paths; these vary from 4 to 5 and 8 feet in width. Of course places where the turf was a little bit uneven were put straight; a mowing machine run over these about once a week or thereabouts keeps the grass smooth and tidy; the edges are clipped at the same time, and being done so often there is practically nothing to pick up; the sun soon makes it disappear. These walks are always smooth and soft, like a Persian carpet; they are very much admired, and especially by ladies, who can walk comfortably along and view the trees, shrubs, herbaceous plants, &c., on either side. From frequent use the grass does not seem to wear off. The only gravelled walks I have is one about 5 feet 4 inches wide round my house, and the carriage drive up to the house, which is a short one; these are kept free from weeds by an occasional sprinkling of salt, well rubbed in at the same time with a besom, and watered in if the weather happens to be dry at the time of application. Finding these grass paths so comfortable to walk upon, economical and advantageous in many ways, I might be allowed to suggest that in many large places which are now under-manned on account of reductions of income owing to agricultural depression, they might materially

reduce their labour by allowing great breadths of grass to run wild which are now kept mown, retaining only where advisable a few of those grass paths of such widths as might be deemed necessary. These grass spaces might be planted with a host of things, such as Snowdrops, Crocus, Daffodils, Lilliums, Roses, and herbaceous plants, which would afford a grand and continuous show of flower from, say, February up until September or later. Such an arrangement would put the owner of those hitherto over-shaven and meaningless spaces into the possession, and that too with

brood, kingfishers nesting in holes in the bank, goldfinches, grey linnets and green ones, besides hosts of other and more common birds. During the ensuing transplanting season, we hope to do something more towards the completion of another already partly begun grass walk, which will be about 300 yards long or thereabouts. When this is done, it may be said of me that I left this place a little more beautiful than I found it, and it may also be said of me, as it was of Shenstone and Scott, that in the formation of their respective places according to their

plants are in the frames, and of hybrid Malmaisons, Duchess of Westminster (salmon-pink), and Maggie Hodgson, of the same colour and fragrance as the old crimson Clove, are favourites. A very fine collection of winter-flowering Carnations promises well for bloom, and of showy flowers at present open a quantity of the large canary-yellow Carnation Cecilia is the finest, and it is not possible to conceive a better when grown as it is at Tring Park. *J. O'B.*

WASTE OF WATER.—Lord Rosebery did well to call attention to this subject in a recent speech at Bathgate. It is such an important subject, and often directly connected with gardening, that I venture, as one of the public who has dug several wells and constructed many water-tanks, to draw attention to the present necessity of being thrifty with water supplies. It has often seemed to me that directly people have the luxury of a tap they lose their conscientiousness. As long as they have to pump their water it is tolerably safe from waste. It is but about two years ago that we came to the end of a cycle of abnormally dry years, five very dry ones and about five more in which the rainfall was not up to the average. The wells were very low all over the country and the springs failed. Yet on several occasions, when chancing to talk about the difficulties consequent on this state of things, people said to me airily and unfeelingly, "Oh, we have no bother; we are supplied by the water company now, and it is so nice. We can draw any amount; we have even got nice little fountains in the garden!" These people were not always close to a large town, so that their water company must have been at considerable expense. They never seemed to consider by what means the company obtain their supply, and that this great and perennial serving out of water must cause extra expense all round to be paid for somehow. Surely it is wise to call attention to the growing recklessness of using "company's" water, and to point out that for social ends one ought to be as careful as possible with the supply of apparently so commonplace an article of necessity as water. *A Consumer.*

THE SPORTING OF LILIUM ALEXANDRÆ.—Last year I wrote that my *L. Alexandræ* had formed a bulb which produced a red flower. This year I have two bulbs of the red variety, and they both repeated the colour. My belief is that the white *L. Alexandræ* is not a hybrid. The red variety may or may not be a hybrid, but the white variety is probably only an albino variation of the red one, while the latter is only a reversion to its original colour. The *L. Alexandræ* var. *rosea* is very pretty; its petals are of a soft pale carmine throughout, with a small number of carmine spots towards their base. The midribs are of a strongly-marked carmine; the margins of the petals are white and wavy. Barring the colour, the white and red varieties are identical, whether in height of plant, in foliage, and form of flower. The white variety has a slight tinge of rose colour on the outside of its petals, which might mean that it is related to a red variety. *E. Bonavia, M.D., July 3, 1905.*

FIG. 14.—A JAPANESE POLYANTHA ROSE IN THE GARDENS AT TRELISSICK, TRURO: COLOUR OF FLOWERS PINK.

SPRAYING.—When some years since we first made known the results obtained by spraying in the United States, and recommended the fruit-growers to follow the example of the Kentish Hop-growers, we were met by two obstacles. Our correspondents had a difficulty in obtaining "London-purple" and "Paris-green," so that we had actually to send to Canada for information as to where to get "London-purple." That difficulty has since been overcome. Then spraying apparatus, though common enough in France and the United States, was scarcely known here outside Hop-gardens. Messrs. STRAWSON, of 71A, Queen Victoria Street, and Messrs. MERRYWEATHER & SONS, 63, Long Acre, exhibited at the recent Park Royal Agricultural show various forms of apparatus well adapted for the purpose in view, so that our fruit-growers can no longer plead that spraying material and spraying apparatus are not to be had.

almost magical quickness, of one of the most lovable and enjoyable elysiums of a wild garden that any man could possibly imagine. Without the experience few people can thoroughly appreciate the quiet and comfortable enjoyment of those grass walks, and I would certainly recommend their use where the walking traffic is not very excessive. During last autumn, winter, and spring, we completed a grass path here 150 yards in length by 5 feet in width; this path has a streamlet and border of flowering trees and shrubs 25 feet wide on one side of it, and a similar but wider border on the other. This is a very enjoyable walk, for although we have the London & Birmingham Railway adjoining, we have in the streamlet, which is here dammed up, a waterhen with her

ideas, they displayed a great deal more taste than they did of worldly wisdom. *W. Miller, Berkswell.*

MALMAISON CARNATIONS AT TRING PARK.—The "Malmaison" Carnation is a prime favourite with Lord Rothschild, and several houses of them at Tring Park (gr., Mr. A. Dye) form one of the special attractions in summer. Probably they have never been seen so good as they are at the present time, when two houses are literally a mass of fine fragrant flowers borne on vigorous specimens of this beautiful Carnation, the plants averaging ten blooms. In each house one side is filled with the old blush-white form, and the other with the pink-tinted variety Princess of Wales. Large quantities of succession

SOCIETIES.

THE ROYAL HORTICULTURAL.

JULY 4.—On the occasion of the usual fortnightly meeting on Tuesday last, in Vincent Square, the body of the Hall was given up to an exhibition of Sweet Peas, held under the auspices of the National Sweet Pea Society. Owing to this circumstance there were no groups of the usual type, and all exhibits other than Sweet Peas were such as were submitted to the various Committees for Certificate.

The ORCHID COMMITTEE recommended awards including three First-class Certificates and three Awards of Merit.

The FLORAL COMMITTEE recommended nine Awards of Merit to the plants enumerated below.

The FRUIT AND VEGETABLE COMMITTEE recommended Awards of Merit to Strawberry Bedford Champion, Tomato Sunrise, and culinary Pea Essex Wonder.

A paper by Professor WEBBER, of Washington, was to have been read, but the mail having been delayed the delivery of the lecture was postponed in consequence.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. Geo. Nicholson, R. Dean, E. H. Jenkins, W. J. James, W. P. Thomson, Chas. E. Pearson, Chas. Jeffries, Chas. Dixon, G. Reuthe, J. T. Bennett-Poe, Geo. Paul, H. J. Cutbush, Jno. Green, C. E. Shea, E. T. Cook, R. W. Wallace, W. Cutbertson, and R. Hooper Pearson.

Awards.

AWARDS OF MERIT.

Carnation Pride of Westbury.—This is a border variety, with very large cherry-red-coloured flowers. The petals are broad and very slightly fimbriated. Strongly fragrant, but the flower is hardly so smooth in appearance as to be considered of the best form. Shown by Sir SAMUEL SCOTT, Westbury Manor, Bucks (gr., Mr. Tapper).

Carnation "Bob Acres."—A border variety, with scarlet flowers of excellent form, and measuring about 2 inches across, very slightly fragrant.

Carnation Countess of Radnor.—Another border variety, but of a very different type to that of Bob Acres. The flowers are 3½ or 4 inches across, very full, and having slightly fimbriated margins. The two varieties above were exhibited by Mr. JAS. DOUGLAS, Edenside Nurseries, Great Bookham.

Delphinium "Snowflake."—A pure white variety, except for a small green spot at the tip of each petal. Shown by J. BRADSHAW, Esq., The Grange, Southgate (gr., Mr. G. G. Whitelegge).

Eschscholtzia "Carmine King."—An attractive variety with carmine-coloured flowers. Shown by Mr. W. H. GARDINER, St. Byth.

Erica cinerea "Skelwith Fold" variety.—A very richly-coloured variety of this well-known hardy Heath, being a deep violet shade of purple. Shown by Mrs. MARSHALL, Ambleside.

Hemerocallis × luteola.—This is a variety raised from a cross between *H. aurantiaca* major and *H. thunbergii*. The flowers are orange-yellow-coloured, of large size, and a considerable number of them are produced on each cymose inflorescence. Shown by Messrs. R. WALLACE & Co., Colchester.

Rose The Dandy.—Described as a hybrid Tea Rose, of exceedingly bright but rich crimson colour, similar to that of Victor Verdier; very fragrant, of small size, but unusually floriferous. The foliage is of large size, almost smooth, and the variety is recommended specially for its value as a garden plant. Shown by Messrs. PAUL & SON, The Old Nurseries, Cheshunt.

CULTURAL COMMENDATION.

Passiflora quadrangularis Bonapartii.—Magnificent flowers of this interesting and showy Passion-flower were shown by PERCY WATERER, Esq., Fawkham, Kent, and a Cultural Commendation was deservedly awarded.

Jacaranda mimosifolia.—A Cultural Commendation was recommended to this fine greenhouse plant, magnificent panicles of flowers being shown by Lady PLOWDEN, Aston Rowant House, Wallingford, Oxon (gr., Mr. W. H. Clarke). The genus belongs to the Bignoniaceae, and the flowers of this species are blue. A supplementary illustration of its flowers was given in the *Gardeners' Chronicle* for September 24, 1904.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), R. Brooman-White, De B. Crawshaw, H. A. Tracy, R. G. Thwaites, F. J. Thorne, H. J. Veitch, W. A. Bilney, G. F. Moore, A. A. McBean, W. Boxall, H. Little, J. Douglas, W. H. Young, F. W. Ashton, and H. T. Pitt.

By arrangement there was but a small display of Orchids, as the Hall was set apart for the Sweet Peas, but the proportion of exceptionally good things staged in the Committee-room was above the average, the awards being as follows:

FIRST-CLASS CERTIFICATE.

Cymbidium Huttoni, from Messrs. CHARLESWORTH & Co., Heaton, Bradford.—A very remarkable and beautiful species, originally discovered by Hutton when collecting for Messrs. Veitch in Java. The species connects *Cymbidium* and *Grammatophyllum*, the large, grooved pseudo-bulbs, each furnished with two or three bright green leaves, much resembling those of *G. multiflorum*. The manner of producing the pendulous racemes of thick-textured flowers is nearest to *Cymbidium Devonianum*. Two varieties were shown, one lighter in colour than the other, the longest raceme bearing fifteen flowers. Flowers about 2 inches across, yellowish-white, densely spotted with purple, the petals being also tinged with purple on the outer halves. Sepals obovate, acuminate, petals narrower and reflexed; side lobes of the lip large and erect, middle lobe oblong, acuminate. A very distinct and desirable species.

Cypripedium × Daisy Barclay (Godefroye leucocheilum × Rothschildianum), from J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. Davies).—A very beautiful hybrid with flowers extended like those of *C. Rothschildianum*, but dwarfed. The flowers are cream-white, evenly marked with irregular lines of claret-purple colour, the labellum being spotted with rose-purple. A good feature in the flower is given by the unusually large and beautifully marked lower sepals displayed behind the labellum.

Cypripedium Lawrenceanum Hyeuan Bank House variety, from R. BRIGGS-BURY, Esq., Bank House, Accrington (gr., Mr. Wilkinson).—Flowers larger than the original form, and with the large dorsal sepals more flatly displayed. Petals and lip light emerald-green; dorsal sepal pure white with emerald-green lines. Plant of free growth, bearing three flowers.

AWARDS OF MERIT.

Cypripedium Godefroye citrinum, from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins).—A very large flower, nearly equal in size and in firm substance to that of *C. bellatulum*. Ground colour pale yellow, the sepals and petals having on the inner halves a beautiful irregular network of claret-purple colour, a few small spots of the same tint being on the face of the labellum.

Laelio-Cattleya × Massungana "Harry Goodson" (*L. tenebrosa* × *L. C. Schilleriana*), from H. S. GOODSON, Esq., Fairlawn, Putney (gr., Mr. G. E. Day).—A very bright hybrid with yellowish sepals and petals tinged and veined with brownish-rose-colour. Lip white at the base, side lobe and expanded front lobe purplish-crimson.

Oncidium crispum "Shrubbery variety," from F. MENTEITH OGILVIE, The Shrubbery, Oxford (gr., Mr. Balmforth).—Flowers large and finely-formed, of a dark chocolate-brown colour with chrome-yellow crest with raised, reddish tubercles. A remarkably dark-coloured flower with wavy edges to the segments.

CULTURAL COMMENDATION

to Mr. Balmforth, gr. to F. MENTEITH OGILVIE, Esq., Oxford, for *Cypripedium niveum*, a small stand with thirty-six fine, pure white flowers being shown.

FRANCIS WELLESLEY, Esq., showed *Laelio-Cattleya × Mrs. Freke-Gould* (*L. tenebrosa* × *C. × intertexta*). A pretty flower with silver-white sepals and petals delicately veined with rosy-lilac on the outer halves; front of lip bright-purple.

DE B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed two plants of *Odontoglossum × crispodinei* (*crispum* × *Coradinei*), a great improvement on the best forms of *O. × Coradinei* and equal in size to *O. crispum*. Both came from the same pod of seeds, but one had the white ground colour and form of lip of *O. crispum*, the other more nearly approached *O. Coradinei*, and had cream-coloured sepals and petals, with one large irregular brown blotch on each sepal and

occasionally one on a petal. Lip whitish with large brown blotches. The other variety had both sepals and petals uniformly blotched.

R. G. THWAITES, Esq., Streatham (gr. Mr. Black), showed *Odontoglossum Pescatorei album* Thwaites' variety, a model pure white flower with orange crest.

HENRY LITTLE, Esq., Twickenham (gr., Mr. Howard), showed a flower of *Laelio-Cattleya × Ivernia Little's variety* (*L. C. callistoglossa* × *L. tenebrosa*), much darker in colour than the original. Sepals and petals purplish-lilac, lip claret-purple.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed the very beautiful *Odontoglossum crispum* "Fearnley Sander," a large and finely-shaped flower, heavily marked with reddish-purple, the fringed margins and a few transverse lines only showing between the markings. Flower purple at the back.

MESSRS. J. BRUCE, Surrey Street, Strand, sent two specimens of *Epidendrum alatum*.

Fruit and Vegetable Committee.

Present: J. Cheal, Esq. (in the Chair); and Messrs. S. Mortimer, A. Dean, W. Pope, E. Beckett, J. McIndoe, Geo. Kelf, F. Q. Lane, H. Parr, T. Coomber, J. Willard, Geo. Norman, and Owen Thomas.

The principal exhibit brought before this Committee was that of a dozen excellent British Queen Pines grown by Mr. Coomber, gardener to Lord LIANGATTOCK, The Hendre, Monmouthshire. For the excellence of culture shown the Committee awarded a Silver-gilt Banksian Medal.

MESSRS. GEO. BUNYARD & Co., Maidstone, Kent, showed sixteen varieties of Strawberries.

A box of fine Peaches, grown as near the metropolis as Regent's Park, was shown by Mr. Geo. Kelf, gardener to Miss ADAMSON, South Villa, Regent's Park. The variety was Dr. Hogg (Silver Banksian Medal).

Mr. G. PENWILL, 80, High Street, Totnes, staged examples of Penwill's Champion Raspberry.

AWARDS OF MERIT.

Strawberry Bedford Champion.—A variety having large oval or roundish-shaped fruits with one or more deep sutures. Their great size is a pronounced characteristic (see p. 11 in our last issue). It is of agreeable flavour, and develops very high colour. Its cropping qualities were demonstrated by several trusses with numerous flowers and fruits. Shown by Messrs. LANTON BROS., Bedford.

Tomato Carter's Sunrise.—A variety with medium-sized fruits of the Perfection type. The plant is a heavy cropper, the individual bunches averaging 1½ lb. weight of about eight to ten fruits. A stem exhibited was carrying five heavy trusses of fruits. Reference was made to this variety on p. 17. Shown by Messrs. CARTER & Co., Holborn, London.

Pea Essex Wonder.—Apparently one of the taller-growing varieties. A very prolific cropper, and well-filled pods were shown. Exhibited by Mr. HORDAY, Romford, Essex.

NATIONAL SWEET PEA.

JULY 4.—The fifth annual show under the auspices of the National Sweet Pea Society was held on the above date in the Hall of the Royal Horticultural Society, Vincent Square, Westminster. Previous exhibitions have been held at the Crystal Palace and Earl's Court, but none was more successful than this one. In many of the large classes there were from six to twelve exhibitors; in the first one, for instance, which called for nineteen bunches, distinct, there were nine exhibitors. The classes for table decorations occupied a large amount of space, and non-competitive collections of Peas in bunches were unusually numerous. The new Hall, therefore, was not in the least too spacious, and, indeed, the Peas left very little space available even for the few things that were submitted for inspection by the Committees of the Royal Horticultural Society. Six new varieties were granted awards.

Much confusion was caused by the non-observance by some exhibitors of the stipulation printed in the Schedule, that "in Classes 1 to 35 inclusive, twenty sprays shall form a bunch—more than this number will disqualify." In Class I (Special Audit Class) it was found that so many exhibitors had exceeded this number that there were scarcely sufficient exhibits remaining to which the prizes could be awarded, and most of

he best flowers having thus been disqualified, we have thought it better not to refer to this class in our report below. It had not been decided at a late hour on Tuesday afternoon what course should be pursued in the matter of awarding the prizes, which included the Silver Cup offered by Messrs. SUTTON & SONS. At the same time the judges had, in our opinion, no option in the matter. Disappointing though it is, the failure to observe a definite stipulation in a schedule, whether by accident or not, can only be followed by disqualification. No other course

Gladys Unwin, Black Knight, Jeannie Gordon, Prince of Wales, Gracie Greenwood, Duke of Westminster, Duchess of Sutherland, Mrs. Walter Wright, Navy Blue, Grey Friar, America, Hon. Mrs. E. Kenyon, Coccinea, Lady Grizel Hamilton, George Gordon, and Maid of Honour. The 2nd place was taken by Mr. W. FIRTH, Wiston Hall, Leicester (gr., Mr. F. Clark). Some of the more notable flowers in this group were Countess Spencer, America, Miss Willmott, and Black Knight. 3rd, Mrs. A. TIGWELL, Harrow View, Greenford, Southall.

Some of the best shown by this firm were King Edward VII., Gracie Greenwood (very refined flowers), Miss Willmott, and Lady Grizel Hamilton. The 2nd prize collection was shown by Messrs. STARK & SON, Great Ryburgh, Norfolk, who had the varieties Jessie Cuthbertson and Enchantress in excellent condition. The 3rd place was taken by Mr. C. W. BREADMORE, Winchester.

Six groups were staged in the class for *twelve bunches in distinct varieties*, that of Mr. A. MALCOLM, Town House, Duns, being easily 1st, although the 2nd prize collection, shown by a fellow-townsmen of Mr. Malcolm, contained some good vases of flowers. The latter was put up by Mr. T. DUNCAN, Fogo School House, Duns, who is to be congratulated on his success as an amateur. The best examples in the premier group of this class were the varieties Bolton Pink (grand flowers), Edward VII., Dora Breadmore, Scarlet Gem, and D. R. Williamson. 3rd, Mr. J. WATSON, The Gardens, Orford House, Ham Common.

Although the trade was excluded from Classes 6 to 10, there was no lack of other competitors. In the class for twenty-four bunches in distinct varieties as many as seven persons competed. This was a strongly-contested class, and the quality throughout was remarkably good. The fortunate exhibitor was Mr. JONES, Bryn, Penylan, Ruabon, who secured the 1st prize for a splendid lot; followed by Mr. A. WOOTTEN, Croft House, College Road, Epsom, 2nd; and by W. H. RAWNSLEY, Esq., Well Vale, Otford (gr., Mr. T. Vickers).

Class 7, for *eighteen bunches*, was also strongly contested, there being no fewer than eight entries, one competitor being disqualified for intermixing grasses among his flowers, this being contrary to the scheduled rules. Mr. STEVENSON, Woburn Place Gardens, Addlestone, was awarded the 1st prize, his premier bunches being those of Gladys Unwin, Lovely, and Black Knight. Mr. E. BEWLEY, Rathgar, Co. Dublin, was 2nd; and Mr. Brown, gr. to W. D. WINTERBOTTOM, Esq., Ashton Hall, near Derby, 3rd.

Twelve Bunches, Distinct.—There were as many as eleven exhibits in this class. The best display was staged by W. A. BANKIER, Esq., Clock House, Epsom (gr., Mr. H. Randall), whose flowers exhibited good cultural skill, the individual blooms being of large substance and good form. The pick of the varieties were Dorothy Eckford and Countess Spencer. 2nd, Mr. W. F. HUTCHINS, Trewarrick, St. Austell. 3rd, Mr. J. T. BLENCOWE, Eastcott Gardens, Kingston Hill.

For Nine Bunches, Distinct.—C. K. WILD, Esq., The Grange, New Eltham, Kent (gr., Mr. E. F. Usher), was 1st. The variety King Edward VII. was shown well by Mr. WILD. The 2nd place was taken by Mr. M. Y. GREEN, The Lodge, Eynsford; and the 3rd by S. F. JACKSON, Esq., Danchurst, Epsom (gr., Mr. E. Boyd).

DECORATIVE CLASSES.

The Decorative Classes were a feature of the exhibition, and demonstrated the adaptability of the Sweet Pea for this branch of the florist's art. The table decorations ran down one side of the Hall, there being no fewer than two dozen tables arranged in one row, and even these did not accommodate the whole. It must have been a heavy task to find the best among the admirable displays. The 1st prize in the Amateur class went to Mrs. E. J. SELL, Kempton Villa, Luton, for a very neat arrangement. The colour of the varieties Agnes Johnston and Lady Grizel Hamilton contrasted well. The 2nd prize was awarded to Mrs. BECKETT, Aldenham House Gardens, Elstree. The 3rd prize went to Miss L. E. KING, Abbeydale, Coggeshall, Essex, with a simple arrangement composed of the variety Lady Grizel Hamilton intermixed with grasses, &c.

Class 39 was open to all exhibitors, and thirteen decorated tables were staged, the best being arranged by Mr. W. MARPLE, Penkridge, near Stafford, who utilised the variety Jeannie Gordon with graceful foliage. 2nd, Miss C. B. COLE, The Vineyard, Feltham. 3rd, Mrs. F. BREWER, Sniffeld House, Richmond.

The best bowl was adjudged to be that staged by Mr. C. W. BREADMORE, 120, High Street, Winchester. It was lightly arranged, the Sweet Peas being well seen, and not hidden by foliage. 2nd, Mr. W. J. NOY, Claypolds Road, Brentford.

The best épergne was arranged by Miss COLE, The Vineyard, Feltham, who utilised a Bruce flower-holder for the purpose. 2nd, Mrs. BREWER, Suffield House, Richmond.

BEST VARIETIES IN EACH COLOUR.

Eighteen classes were devoted to an exhibition designed to illustrate the best varieties of a particular

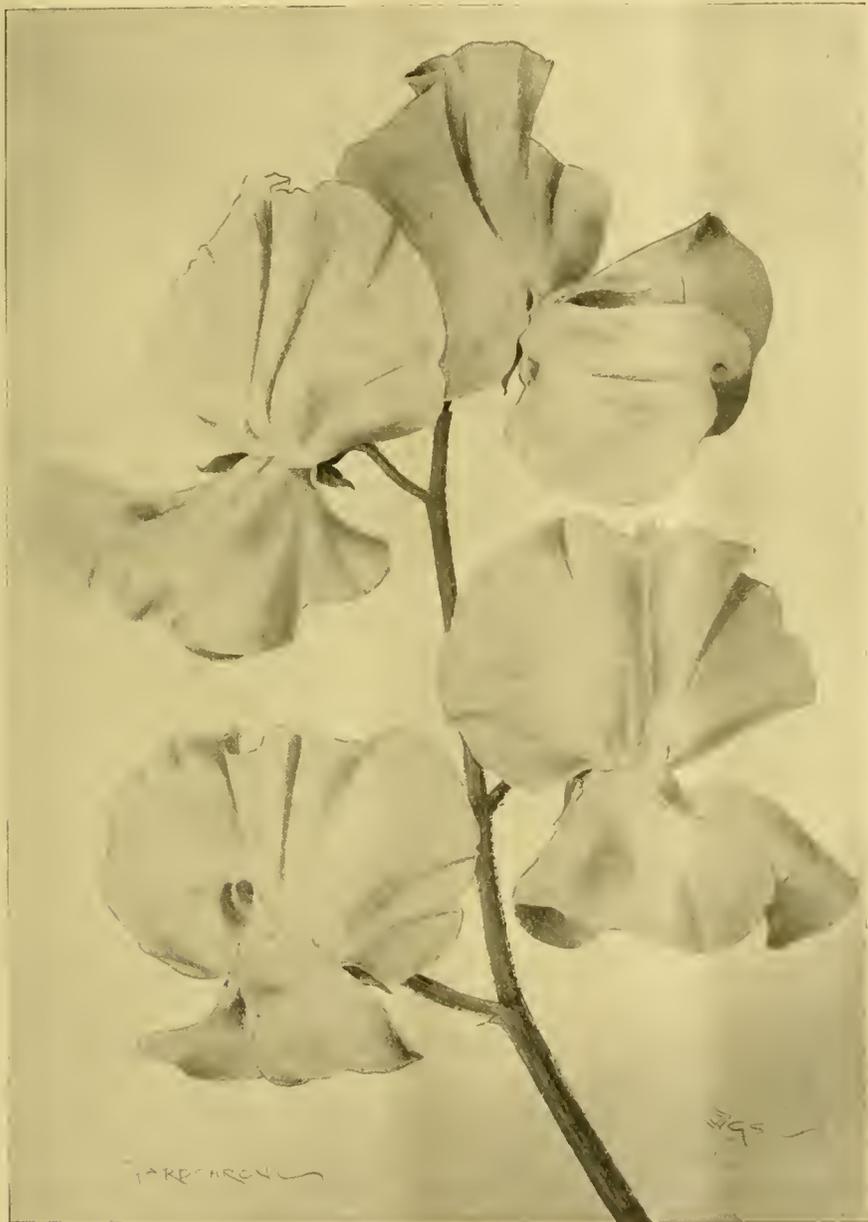

FIG. 15.—SWEET PEA "HELEN LEWIS": THE BEST NOVELTY AT THE SHOW ON TUESDAY LAST. (SEE P. 36.)

would be fair to those exhibitors who are careful to observe the conditions. Much work had to be done by Mr. HORACE J. WRIGHT and his Committee, whose task was the more severe owing to the matter just described.

COLLECTIONS OF VARIETIES.

In the class for a *Collection of nineteen Varieties* to include one variety only of each colour given in the Society's classification table there were six exhibits. As in the preceding class some confusion obtained with regard to conditions, the result being that two competitors were disqualified. The premier prize was secured by Messrs. CLARK & CO., Maison Dieu Road, Dover, who had a fine assortment of the best colours, the individual flowers showing good culture. The varieties staged were Dorothy Eckford, Miss Willmott,

For *thirty-six Bunches, Distinct*, there were five competitors. The quality of the exhibits was generally good, the 1st prize being secured by A. S. HAYMAN, Esq., Hapsford House, Frome (gr., Mr. F. Ackland), who had a bright array of bold, well-developed flowers. As a selection of the best flowers in this exhibit we may include Countess Spencer, Countess of Radnor, Navy Blue, Janet Scott, Emily Eckford, and Salopian. Mr. C. W. BREADMORE, 120, High Street, Frome, was placed 2nd; followed by Messrs. J. HOUSE & SON, Westbury-on-Trym.

Twenty-four Distinct Varieties, in bunches of twenty sprays each.—There were five exhibitors in this class, and keen competition resulted. 1st honours fell to Messrs. SALTMARSH & SON, Chelmsford, who had a remarkably good collection displayed to advantage.

colour. The colours are those adopted in the Society's classification list, which, on the whole, are satisfactory, but the difficulty there is in drawing arbitrary distinctions in the colours is apparent in several of the classes where room is left for much difference of opinion, as shown by the fact that several varieties were exhibited with success in more than one class. As a guide to those who require to cultivate a limited number of varieties, and wish them to be as distinct as possible, the results of the competition have some value, and we therefore append sufficient details for this purpose. The classes were arranged for two bunches, distinct.

In that for *blush-coloured flowers* we could only find the exhibit awarded the 3rd prize, the varieties being Countess of Aberdeen and Duchess of Sutherland.

Crimson.—There were nearly one dozen exhibits, and the comparatively new varieties Scarlet Gem, and King Edward VII. were shown in almost all of them.

Cerise.—Coccinea was the only variety exhibited in this class.

Rose and Carmine.—The 1st prize was gained by the varieties Prince of Wales and Mrs. Dugdale; the 2nd prize by Prince of Wales and Royal Rose, and the 3rd prize by the Prince of Wales and Lord Rosebery.

Pink.—The varieties Mrs. K. Smith and Countess Spencer won the 1st prize, Countess Spencer and Janet Scott the 2nd prize, and Gladys Unwin and Prima Donna the 3rd prize.

Orange Shades.—In the 1st and 2nd prize exhibits, the varieties were Gorgeons and Miss Willmott; and the varieties Miss Willmott and Lady Mary Currie won the 3rd prize.

Yellow and Buff.—The Hon. Mrs. Kenyon was exhibited in all the three 1st-prize exhibits, the companions being Lady Ormsby Gore, Queen Victoria, and Venus, in the order in which they are here given.

Lavender Colour.—In the three first exhibits the beautiful variety Lady Grizel Hamilton was shown, the companion varieties being those following in the order named—Countess of Radnor and New Countess.

Blue.—The 1st prize for blue flowers was won by the varieties Navy Blue and Captain of the Blues. The 2nd prize by Emily Eckford and Countess Cadogan; and the 3rd prize by the varieties Rev. D. R. Williamson and Miss H. C. Philbrick.

Mauves.—The three best varieties in this class were Dorothy Tennant, Mrs. Walter Wright, and Admiration.

Violet and Purple.—The Duke of Westminster, Mrs. Walter Wright, and the Duke of Clarence won prizes.

Maroon and Bronze.—The varieties Black Knight and Othello were successful for 1st, 2nd and 3rd prizes.

Magenta. In the 1st and 2nd prize exhibits the varieties were George Gordon and Calypso.

Picoté edged.—In the three best exhibits the varieties were Lottie Eckford and Dainty.

Striped and Flaked Red and Rose Colour.—America, Aurora, and Jennie Cuthbertson were successful in this class.

Striped and Flaked Purple and Blue Colour.—Princess of Wales and Senator.

Bicolor Peas.—1st, Jeanie Gordon and Triumph; 2nd, Triumph and Prince Edward of York.

Fancy Varieties.—1st, Agnes Johnston and Gracie Greenwood; 2nd, Gracie Greenwood and Duchess of Westminster; 3rd, Gracie Greenwood and Agnes Johnston.

AWARDS TO NEW VARIETIES.

Helen Picree.—Flowers bluish-purple and white, curiously blended, the deeper-coloured veining being very pretty; standard erect. Those shown had three, and in some cases two flowers only on a spike (Award of Merit).

Evelyn Byatt. Standard erect, of orange-red colour; wings of deeper red, of rose rather than orange shade. Generally two but occasionally three flowers on a spike (Award of Merit).

Both of these varieties were exhibited by MESSRS. WATKINS & SIMPSON, 12, Tavistock Street, London.

Helen Lewis.—This is the handsomest of the novelties exhibited for the first time, and was therefore awarded a First-class Certificate and a Silver Medal, being the best novelty for the year (see fig. 15, p. 35). The specimens were shown by Mr. J. WATSON, jun., the

Gardens, Orford House, Ham Common, and were splendidly cultivated flowers. Generally there were four very large flowers, and occasionally three flowers on a spike; standard erect and very spreading, colour bright salmon-red; the wings are deeper in colour, of rosy shading. The same variety was also shown by other exhibitors under the names of Mrs. Mark Firth and the Hon. Mrs. C. R. Spencer.

Mrs. Hardcastle - Sukes.—This variety has large pink flowers of a bright and attractive shade of colour. Generally there are three flowers on a spike. Shown by Mr. BOLTON, Carnforth (Award of Merit).

Tom Bolton.—A variety with mauve-coloured flowers, approaching the shade of Lady Grizel Hamilton. Shown by Mr. BOLTON, Carnforth (Award of Merit).

TRADE EXHIBITS.

Mr. ROBERT SPENHAM, Tenby Street, Birmingham, staged a collection of many of the finest varieties (Large Silver Medal).

Messrs. WEBB & SONS, Wordsley, Staffordshire, put up a very artistically-arranged collection. They used yellow-coloured drapery and glass girandoles to enhance the effect (Large Silver Medal).

Messrs. JOHN PEED & SON, West Norwood, London, contributed a commendable collection of the most popular varieties (Silver Medal).

Adjoining the last-named group was a similar one put up by Messrs. J. CHEAL & SONS, Crawley (Large Silver Medal).

Messrs. BARR & SONS, King Street, Covent Garden, utilised a staging with a groundwork of "art" cloth on which to display a collection that included many of the best varieties (Large Silver Medal).

Messrs. WM. CUTBUSH & SON, Highgate, London, N., arranged an exhibit of excellent flowers in fancy vases and in bamboo epergnes. The method of staging was pleasing, and different to that adopted by the majority of exhibitors (Large Silver Medal).

Messrs. C. STARK & SON, Great Ryburgh, Norfolk, showed a bright collection of well-known varieties (Large Silver Medal).

Messrs. JONES & SONS, Coton Hill Nurseries, Shrewsbury, put up a collection of well-grown flowers, amongst which we noticed some of the more recent novelties (Silver-gilt Medal).

Mr. HENRY ECKFORD, Wem, Shropshire, sent a beautiful display of these lovely flowers. Included were most of the best and newest varieties, the majority of which have been raised by the exhibitor. The whole collection showed perfect culture (Gold Medal).

Messrs. GILBERT & SON, Bourne, Lincolnshire, were represented by a collection in which blue-coloured varieties were prominent. Gypsophila was utilised freely with the Sweet Peas (Silver Medal).

Messrs. G. & A. CLARK, Ltd., Dover, had a good display in fifty varieties. The quality of the flowers was commendable (Silver-gilt Medal).

Some excellent flowers were staged by Mr. ROBT. BOLTON, Warton, Carnford. The quality was equally meritorious throughout the collection (Gold Medal).

Messrs. E. W. KING & Co., Coggeshall, Essex, used tall flower bowls and taller vases for displaying their group of these flowers. Ferns, small Palms, Gypsophila, &c., were liberally used for greenery (Large Silver Medal).

Mr. CHAS. BREADMORE, Winchester, contributed a nice collection staged in vases and in epergnes, and plentifully relieved with foliage plants. A vase containing the variety Dora Breadmore was very effective in appearance (Large Silver Medal).

A very bright lot was displayed by Messrs. BAKERS, Wolverhampton and Codsall. The flowers showed exceptional culture, and the varieties were of the best. Altogether an excellent group, and displayed with good taste (Gold Medal).

Messrs. CARTER, High Holborn, London, arranged their group in three large glass epergnes and in fancy glass vases beneath the taller receptacles. Red and scarlet varieties were prominent in this group (large Silver Medal).

Messrs. DOBBIE & Co., Rothesay, showed some well-grown flowers in most of the best known varieties. The display was enhanced by yellow drapery and a white table ground (Gold Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, arranged a collection on a high staging. The quality of the flowers was commendable. The "haulm" was freely used among the flowers, furnishing a natural and pleasing foliage (Silver-gilt Medal).

Mr. W. J. UNWIN, Histon, Cambridge, put up a collection, among which were several seedlings of merit (Large Silver Medal).

Messrs. WATKINS & SIMPSON, Tavistock Street, Covent Garden, London, staged a group of flowers, among which the varieties Gladys Unwin and Evelyn Myatt were conspicuous (Silver Medal).

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 22.—Meetings in the summer months are always smaller, and on the date of the last meeting there were only a few plants shown.

W. THOMPSON, Esq., Stone (gr. Mr. Stevens), sent a nice group of plants, prominent in which was a grand specimen of *Coelioda Noezliana*. A new hybrid *Odontoglossum*, the parents of which were *O. Halli* × *O. Rolfeae*, and named *O. × lapidense*, was voted an Award of Merit (Bronze Medal for group).

PHILIP SMITH, Esq., Sale (gr. Mr. Kitchen), staged a group of plants, among which were noticed *Laelio-Cattleya* × *Martinetti* and *Cypripedium* × *Annie Measures*, a good form of *C. Chamberlainianum*. A Bronze Medal was awarded for the group.

Votes of Thanks were passed to Messrs. A. J. KEELING & SON, Mr. JOHN ROBSON, and Father CROMELEHOLME for contributions to the meeting. P. W.

SOUTHAMPTON ROYAL HORTICULTURAL.

JUNE 28, 29.—The annual Rose and summer flower show was held as usual on the Royal Pier, and was a success from a horticultural point of view. Considering the early date and the not too favourable weather, Roses were good in quality if not very numerous. In the amateur division Tea and Noisette varieties were of high-class quality. The arrangements were, as usual, satisfactory in the hands of Mr. C. Fudge, who has acted as secretary for thirty years.

ROSES (OPEN CLASSES).

That for forty-eight distinct varieties was the leading class. Messrs. D. PRIOR & SON, Colchester, won the 1st prize easily with medium-sized, highly-coloured examples of popular varieties. Messrs. JABMAN & Co., Chard, were 2nd.

Trebles in eighteen varieties were splendidly shown by the two firms already mentioned.

In the classes for twelve Tea or Noisette Roses, six blooms of any one dark-coloured Rose, and six blooms of any light-coloured Rose, Messrs. PRIOR followed up their previous success by winning 1st prize in each class.

For eighteen varieties of garden or decorative varieties, three trusses of each, Mr. G. ELLWOOD, gr. to W. H. MYERS, Esq., M.P., Swanmore House, Bishop's Waltham, won the 1st prize with popular varieties.

For six bunches of single-flowered varieties, Mr. ELLWOOD won easily with such typical varieties as The Lion, Leuchstern, Paul's White, Andersoni, and Brunonis. Messrs. B. LADHAMS, The Nurseries, Shirley, Southampton, were 2nd.

In the section for gardeners and amateurs, the class for twenty-four distinct flowers was won by Mr. Neville, gr. to F. W. FLIGHT, Esq., Cornstiles, Twyford, Winchester, who was distinctly ahead with full-sized bright blossoms.

Exceptionally keen was the competition for twelve Tea or Noisette varieties. Mr. NEVILLE again won with superb blooms of the varieties Mrs. E. Mawley, Innocente Pirola, White Maman Cochet, Muriel Graham, Anna Ollivier, and Maman Cochet. Dr. SEATON, Woodside Cottage, Lymington, was 2nd.

Nine exhibitors competed in the class for twelve blooms in not fewer than eight varieties; the best, an even set of good blooms, coming from Dr. C. LAMP-LOUGH, Kirkstall, Alverstokey.

For twelve bunches of garden Roses, Mr. ELLWOOD won with huge bunches of Papa Gontier, Gardenia, Claire Jacquier, Thalia, Carmine Pillar, and Madame Plantier. Mr. W. Valentine, gr. to H. E. SUGDEN, Esq., Ingersley, Chilworth, was 2nd.

The premier bloom in the show was one of Mrs. E. Mawley, belonging to Mr. FLIGHT; and the premier H.P. was a bloom of *Gustave Piganneau* belonging to the same exhibitor.

Baskets of Roses were of noteworthy quality. Miss MILLER, St. Thomas, East Cowes, won with the variety Madame Abel Chatenay, arranged in a mass.

Mr. T. Hall, gr. to Sir S. MONTAGUE, Bart., South Stoneham House, had the best-arranged vase of Roses amongst eleven competitors.

The best arranged group of miscellaneous plants came from Mr. E. WILLS, Winchester Road Nursery, Southampton.

Of hardy cut flowers, those from Messrs. LADHAMS shown in twelve bunches were the most noteworthy.

Sweet Peas made a great display. Messrs. TOOGOOD, BREADMORE, and CARTER all offered prizes. Mr. F. COZENS, Rownhams, with exceptionally fine blossoms,

won easily in one class; and Mr. J. Hughes, gr. to A. P. RALLI, Esq., Twyford Lodge, Winchester, won Mr. Breadmore's leading prize.

VEGETABLES

were shown numerously and well. Mr. ELLWOOD exhibited grandly in the classes for six dishes, where the prizes were provided by Messrs. TOOGOOD, MESSRS. SUTTON & SONS, and MESSRS. CARTER & CO.

There was little fruit shown. Mr. ELLWOOD was the only exhibitor of two bunches of black Grapes, with a commendable exhibit of Black Hamburg.

For two dishes of Strawberries, Mr. J. MATTHEWS won with superb examples of Royal Sovereign and Sir Joseph Paxton. Mr. ELLWOOD was 2nd with the varieties Leader and Royal Sovereign.

Trade exhibits were numerous and good. Gold Medals were awarded to Mr. C. Breadmore for Sweet Peas, and to Messrs. B. Ladhams & Son for a well-planted rockery and cut herbaceous flowers. Silver-gilt Medals were awarded to Messrs. Sutton & Sons for Melons, Peas, Tomatos, and Cucumbers; to Messrs. Toogood & Sons for Sweet Peas; to Messrs. Jarman & Co. for Sweet Peas, Roses, Zonal Pelargoniums, and Sweet Sultan The Bride, and Bridegroom.

NATIONAL ROSE.

JULY 6.—The annual exhibition of the National Rose Society on Thursday last was held this year for the first time in the gardens of the Royal Botanic Society, Regents Park. So far as the gardens themselves are concerned, they offer an excellent site for such a show, owing to the suitability of the surroundings. The flowers were staged in three tents adjoining the corridor, and together they covered a space exceeding 20,000 square feet. The exhibits, however, were not sufficient to furnish them fully.

Comparing the entries with those of last year they were not unfavourable, but many who entered were afterwards unable to exhibit. The Champion Trophy in the nurserymen's competition was won by Messrs. B. R. CANT & SONS, Colchester; and in that confined to amateurs by E. B. LINDSELL, Esq., Hitchin, who has won the same award so many times previously. Of new Roses there were several shown, and Gold Medals were awarded to two varieties, and an Award of Merit to a third variety.

The Hon. Secretary, Mr. EDWARD MAWLEY, was busy, and tried to make the most of the advantage, which was described in the Annual Report as follows—“For the first time in the Society's existence the Committee will have an entirely free hand in all the arrangements connected with their Metropolitan Show.”

HER MAJESTY THE QUEEN visited the show shortly after noon, and Miss Willmott and other ladies and gentlemen accompanied her through the tents. We should mention that an electric fan was affixed to the middle tent to afford ventilation.

NURSERYMEN.

MIXED CLASSES.

There were four exhibits staged in the class for *Twenty-two Blooms, Distinct Varieties*, therefore the flowers in this class alone numbered 288. The general quality of the blooms was good, and there was less evidence of injury by bad weather than might have been expected. The best collection was that shown by Messrs. B. R. CANT & SON, Old Rose Gardens, Colchester, and they were awarded 1st prize, including the CHALLENGE TROPHY AND GOLD MEDAL. We can only mention a few of the best flowers, which were those following:—Mrs. Cocker, Madame de Watteville, Helen Keller, Ethel Brownlow (wonderfully pretty), Victor Hugo, Marchioness of Downshire, Killarney, Catherine Mermet, Tom Wood, Mrs. John Laing, A. K. Williams (small, but very good in quality), Duchess of Portland (a delightful lemon-coloured Tea), Mrs. Mawley, and Marie Baumann. The judges had much difficulty in separating the 2nd from the 1st prize exhibit, for the collection from Messrs. A. DICKSON & SONS, Newtownards, co. Down, was very little inferior. Among the brightest blooms were Killarney, Ulrich Brunner, Horace Vernet, Mildred Grant, Captain Hayward, Prince Arthur, Hugh Dickson, Chas. Darwin, C. J. Grahame, Fisher Holmes, &c. 3rd, Messrs. D. PRIOR & SON, Myland Nursery, Colchester. 4th, Messrs. FRANK CANT & Co., Braiswick Nursery, Colchester.

Forty Distinct Varieties, three Blooms of each.—There were three exhibits in this class for forty trebles, and the best of these was one from Messrs. ALEX. DICKSON & SONS, Royal Irish Nurseries, Newtownards, co. Down. Some of the most effective varieties were those following:—Hugh Watson (very bright reddish-cerise colour), Ulrich Brunner, Tom Wood,

Mrs. W. J. Grant, Bessie Brown, Earl of Dufferin, Pharisæa, Margaret Dickson, Lady Ashtown and Mildred Grant. In the 2nd prize exhibit there were very pretty brightly-coloured flowers, smaller in size, but less damaged by weather than those in the 1st prize exhibit. Victor Hugo, Duke of Teck, White Maman Cochet, Comte de Raimbaud, and Mildred Grant were especially nice. This collection was shown by Messrs. B. R. CANT & Co., Colchester; and the 3rd prize was awarded to Messrs. D. PRIOR & SONS, Mylands Nursery, Colchester. This class is very exacting, each exhibitor in it having to stage 120 flowers.

Forty-eight Blooms, Distinct Varieties.—In this class there were six exhibits, and the competition occasioned the judges such an amount of work that they were late in making the awards. Eventually the 1st prize was awarded to Mr. HUGH DICKSON, Royal Nursery, Belfast. The best varieties as shown were Bob Davidson, Mrs. Ed. Mawley, Mrs. Jno. Laing, Madame Hoste, Margaret Dickson, Her Majesty, Horace Vernet, Fisher Holmes, Madame Delville, Gustave Piganneau, Earl Dufferin, and others.

The other exhibitors in the class were Messrs. COOLING & SONS, Bath; Messrs. G. & W. H. BURCH, Peterborough; THE KING'S ACRE NURSERY Co., King's Acre, Hereford; Mr. GEO. MOUNT, Canterbury, and Messrs. J. BURRELL & Co., Cambridge.

Twenty-four Blooms, Distinct Varieties.—In this class there were four exhibits, and 1st prize was awarded to Mr. CHAS. TURNER, Slough, who showed the following varieties:—Back row: A. K. Williams, Robert Scott, Dr. André, Maman Cochet, Marie Baumann, Bessie Brown, Ulrich Brunner, Her Majesty; Centre row: Mrs. Jno. Laing, Comte Raimbaud, Ulster, Horace Vernet, Ellen Drew, Countess of Rosebery, White Maman Cochet, Chas. Lefebvre; Front row: Reynolds Hole, Muriel Grahame, Fisher Holmes, Duchesse de Morny, Duke of Edinburgh, Xavier Olibo, Alfred Celorb, and Catherine Mermet. Mr. JNO. MATTOCK, The Rose Nurseries, New Headington, Oxford, was 2nd; and Mr. GEO. PRINCE, Longworth, 3rd. The weather has evidently been unkind to Mr. PRINCE'S Tea and Noisette Roses this year. The remaining exhibitors in this class were Messrs. JAMES SIMPSON & SONS, Dundee.

TEA AND NOISETTE ROSES.

Twenty-four Blooms, Distinct Varieties.—Four competed in this class. Three collections ran each other very close for supremacy, but the final award resulted in Messrs. FRANK CANT & Co., Colchester, being placed 1st. The quality was certainly not up to the standard of last year, but some good flowers were included, notably Maman Cochet, Mrs. Ed. Mawley, Souvenir d'Elise Yardon, Ethel Brownlow, Mme. de Watteville, The Bride, Comtesse de Nadaillac, and White Maman Cochet. The 2nd place was awarded to Messrs. B. R. CANT & SONS, Colchester. This collection also contained some good individual flowers, notably Mrs. Edwin Mawley, Catherine Mermet, Souvenir de Pierre Notting, and Maman Cochet. 3rd, Messrs. D. PRIOR & SON, Colchester.

For Twelve Blooms, Distinct Varieties.—Five competed, the best dozen flowers being those of Mr. JOHN MATTOCK, The Rose Nurseries, Headington, Oxford, who had the varieties Maman Cochet, Bridesmaid, Niphotos, Souvenir d'Elise Yardon, Muriel Grahame, The Bride, Comtesse Nadaillac, Mrs. Ed. Mawley, Ernest Metz, Medea, Souvenir d'un Ami, and Souvenir de Pierre Notting. The 2nd prize collection was not far behind in quality, although neither was first-class; it was put up by Messrs. J. BURRELL & Co., Howe House Nurseries, Cambridge. The best flowers were Maman Cochet, The Bride, and Comtesse de Nadaillac. 3rd, Mr. CHAS. TURNER, Royal Nurseries, Slough.

BLOOMS SHOWN IN VASES AND BAMBOO TRIPODS.

Twenty Distinct Varieties, Three Blooms of Each.—This was quite a novel class, for the flowers were shown in twenty bamboo tripods, each exhibit being arranged on a space not exceeding 7 feet by 3 feet. These tripods were arranged with one stand about 15 inches high at the back and two in front about 1 foot high. The effect in this class was very gratifying. Among five exhibitors the best was Mr. HUGH DICKSON, Royal Nurseries, Belfast, and he was awarded the 1st prize. The foliage of each variety could be seen, and this increased the effect of the display. Those varieties shown best were Ulrich Brunner, Hugh Dickson, Horace Vernet, Gustave Piganneau, J. B. Clark (a red H.P. Rose shown last year), Madame Delville, Duchess of Bedford, and Perle von Godesberg. The 2nd prize was won by Mr. CHAS. TURNER, Royal Nurseries, Slough; and the 3rd prize by Messrs. G. & W. H. BURCH, Peterborough.

There were three entries in the class for fourteen distinct varieties of TEAS and NOISETTES, the 1st prize going to an excellent lot of flowers belonging to Messrs. FRANK CANT & Co., Colchester. The schedule stipulated that they should be shown in vases, which gave better scope for display than the show boxes.

Among the best flowers we may select Mrs. Edward Mawley, White Maman Cochet, Madame Cusin, Maman Cochet, Muriel Grahame and Madame de Watteville. The 2nd place was taken by Messrs. D. PRIOR & SON, Myland Nursery, Colchester. Maman Cochet, White Maman Cochet and Mrs. Edward Mawley were prominent varieties in this group. 3rd, Mr. GEO. PRINCE, Longworth.

In the NURSERYMEN'S CLASS for Exhibition Roses shown in VASES, to include half-a-dozen Tea and the same number of Noisette Roses, seven blooms of each variety, the whole to occupy a space not exceeding 6 feet by 3 feet, there were three competitors. The 1st prize was secured by Messrs. DICKSON & SONS, Newtownards, Co. Down. Lighter-coloured varieties predominated, the best examples being Ulrich Brunner, Frau Karl Drusehki, Mildred Grant, Mrs. W. J. Grant, and Dean Hole. The 2nd prize was awarded to Messrs. FRANK CANT & Co., Colchester, whose flowers were smaller, but possessed much refinement; Maman Cochet, Madame Cusin, Madame de Watteville, and Bessie Brown were some of the better examples. 3rd, Mr. GEO. MOENT, Canterbury.

In the similar class to the last-named for nine varieties only there were four entries, but the 1st prize group led easily. This was shown by Messrs. FRANK CANT & Co., Colchester, whose flowers were good all through the exhibit. It included Maman Cochet (grand flowers), Mrs. E. Mawley, White Maman Cochet (shown well), Ernest Metz, Innocenti Pirola, Madame de Watteville, Golden Gate, Madame Cusin, and Madame Hoste. The 2nd prize was taken by Mr. GEO. PRINCE, nurseryman, Longworth, whose flowers were arranged somewhat stiffly. 3rd, Mr. GEO. MOUNT, Canterbury.

DECORATIVE OR GARDEN ROSES.

This section includes any variety that is not considered to be sufficiently good in quality when cut to be classed as an exhibition Rose. Everyone should know that amongst the merely decorative Roses there are many of the highest value for garden decoration, the single and semi-double flowers, the Polyanthia, like that shown in fig. 14, Multiflora (see fig. 13) and Rambler types, are all so free in flowering that they are essentially garden Roses. The exhibits in this section were staged in order to show as far as possible the foliage and habit of growth of each variety. All Hybrid Perpetuals, other than single flowers, were excluded, and all Teas, Hybrid Teas, and Noisettes mentioned in the National Rose Society's catalogue of exhibition Roses.

Thirty-six Distinct Varieties.—There were three exhibits in this class, each staged on a separate table, round which the visitor could walk and examine the flowers from every point. The 1st prize was awarded to Messrs. FRANK CANT & Co., and among the varieties shown some of the most gorgeous were Irish Glory (large single red), Gustave Regis (semi-double, lemon-yellow coloured), Marquise de Salisbury, Laurette Messimy, the brilliant Rose Liberty, Hélène (pink), Céline Forestier, Madame Antoine Mari (rich pink), Gruss an Teplitz, &c. 2nd, Mr. JNO. MATTOCK, of Oxford; and 3rd, Messrs. PAUL & SONS, The Old Nurseries, Cheshunt.

Eighteen Distinct Varieties.—In this smaller class Mr. GEO. PRINCE, The Oxford Nurseries, Longworth, won 1st prize, showing specially well the varieties Marquise de Salisbury, Mme. Abel Chateaux, Blush Rambler, Bellefleur, Rosa himalaica, &c. R. himalaica, with its pure white, numerous flowers, and richly yellow anthers, was perfectly delightful. 2nd, Mr. CHAS. TURNER, Slough.

Eighteen Distinct Summer Flowering Varieties.—Mr. CHAS. TURNER won 1st prize in this class, and we much admired such varieties as Alba rosea, Crimson Damask, Red Damask, Meg Merrilies, &c. 2nd, Messrs. COOLING & SONS, Bath.

GROUPS OF ROSES.

We have never seen such fine groups of Roses shown at the national exhibition before. Class 15 was for a representative group of Roses placed on the ground. The varieties were to represent the different sections as much as possible. Ferns, &c., could be used for relief and blossoms were shown in all sorts of suitable receptacles. Whole plants, apparently with their feet in buckets of water, were shown of the Rambler varieties in the exhibit from Messrs. PAUL & SON, The Old Nurseries, Cheshunt, who were deservedly awarded the 1st prize, which consisted of a Gold Medal and £5. A large plant of the variety Hendersoni, some 6 feet high and 4 feet across, was much admired, its large richly pink single flowers were irresistibly attractive. Indeed, the varieties in this group were so interesting and good that we moved past with reluctance. The limitations imposed by space and time are, however, imperative. 2nd, Mr. CHAS. TURNER; and 3rd, Mr. GEO. MOUNT. That it was possible to place Mr. GEO. MOUNT 3rd in such a competition will suffice to emphasize the general good quality of these groups.

Representative Group of Cut Roses, arranged on a space not exceeding 100 square feet.—The 1st prize

offered in this class was equal in value to that in the preceding class. Messrs. GEO. JACKMAN & SON, Woking, were 1st; Mr. GEO. MOUNT, 2nd; and Messrs. W. SPOONER & SON, Arthur's Bridge Nursery, Woking, 3rd.

OPEN CLASSES.

For Twelve Blooms of Hybrid Tea Roses, to be of varieties included in the Society's list, five exhibits were entered. The best were shown by Messrs. DICKSON & SONS, Newtownards, Co. Down, who had a really excellent dozen flowers; the variety Dean Hole was beautiful, also Mildred Grant (large flower), Killarney, and Liberty. The 2nd place was awarded to Messrs. F. CANT & CO., Colchester, who had the variety Exquisite in good condition.

The class for eighteen blooms of any white or yellow variety made an excellent feature, and was much admired. The dozen-and-a-half flowers set up by Messrs. F. CANT & CO., Colchester, were admirable. They were of the variety White Maman Cochet, and every flower was a specimen. They were displayed in a bamboo epergne, according to the conditions of the schedule. These were followed by Messrs. DICKSON & SONS' epergne of Frau Karl Druschki, with large flowers, but lacking substance.

In a similar class, but with white and yellow varieties excluded, the stand of the variety A. K. Williams, staged by Messrs. B. R. CANT & SONS, Colchester, was exquisite and quite one of the finest exhibits in the show. The rich colour of this variety was admirably developed and every flower was of perfect shape. The 2nd prize was awarded Messrs. DICKSON & SONS, Newtownards, Co. Down.

For twelve blooms of distinct varieties, in commerce since 1902, half-a-dozen exhibitors competed, the premier dozen flowers being those of Messrs. DICKSON & SONS, Newtownards, Co. Down, who had William Notting, Pharisæer, Dean Hole, Florence Pemberton, Gustave Grunerwald, Countess Annesley, Mrs. David McKee, Dr. J. Campbell Hall, Alice Lindsell, Lady Ashton (fine flower), Countess of Derby, and Madame Paul Olivier (excellent flower). 2nd, Messrs. HUGH DICKSON, Royal Nurseries, Belfast—J. B. Clark (a large scarlet-rose coloured variety, was admired by H.M. the Queen), Hugh Dickson, Prince de Bulgarie, &c. 3rd, Messrs. B. R. CANT & SONS, Colchester.

The best arch decorated with not more than two varieties of Climbing Roses was that arranged by Mr. CHAS. TURNER, Royal Nurseries, Slough. The variety Crimson Rambler almost covered one half of the Bamboo arch with trusses of flowers, while the other was furnished with sprays of Thoresbyana, the white flowers of which formed an excellent contrast to the Crimson Rambler. Mr. GEO. PRINCE was the only other exhibitor, and he was awarded 2nd prize for somewhat similar varieties.

Four groups of single varieties were staged in Class 26 to include twelve distinct varieties. A very charming collection staged by Messrs. COOLING & SON, Bath, was given 1st honours, followed by Messrs. PAUL & SON, Cheshunt, 2nd; and by Messrs. FRANK CANT & CO., Colchester, 3rd. The premier group had R. atropurea, Irish Brightness (good examples), Rosa Andersoni, R. himalaica (a charming white form), Cooling's Crimson Bedder and others in first class condition.

The best nine varieties of Buttonhole Roses was put up by Mr. GEO. PRINCE, Longworth, Berks. Such charming and miniature varieties as Beryl, Madame Anna Chartron, Ma Capucine, Papa Gontier, &c., were eminently suitable for the purpose required. 2nd prize was taken by Mr. JOHN MATTOCK, New Headington, Oxford, with a clean and well-formed collection, the varieties Lady Roberts and Meta being admirable for buttonhole purposes. 3rd, Messrs. F. CANT & CO., Colchester.

AMATEURS.

The principal class in the Amateur's section was that requiring thirty-six blooms distinct, and the 1st prize included the Challenge Trophy. Mr. E. B. LINDSELL, Hitchin, again won this with a very fine lot of blooms, being followed by the Rev. J. H. PEMBERTON, Havering-atte-Bower, and W. BOYES, Esq., Duffield Road, Derby.

In the following class for twenty-four blooms, the Rev. J. H. PEMBERTON was 1st; Mr. LINDSELL, 2nd; and Mr. A. TATE, Leatherhead, 3rd. The Grahame Memorial Prize offered to growers of fewer than 500 plants, for exhibits of nine blooms distinct, was won by Mr. R. W. BOWYER, Hertford Heath, Hertford. Mr. W. R. HAMMOND, Grovelands, Burgess Hill, won the Ben Cant Memorial Prize; and Mr. C. F. II, LESLIE, Hertingfordbury, obtained the President's Cup for the best collection of twelve blooms, limited to growers entitled to exhibit in Divisions E, F, and G.

The Challenge Trophy offered for the best collection of eighteen blooms of Tea and Noisette varieties was won by the Rev. F. R. BURNSIDE, Rochford, Essex; and he also won the following class for eighteen Teas and Noisettes, winning in this class the Cocker Cup.

Mrs. O. G. ORPEN, Colchester, who has previously shown exceedingly tasteful dinner-table decorations

won 1st prize in Class 66, which was for a decoration of cut Roses for the dinner-table, using in this instance the beautiful variety Paul's Single White.

NEW SEEDLING ROSES.

Gold Medals were awarded to—

Tea Rose "Mrs. Miles Kennedy," a white variety with very little pink-coloured blush; and to—

Hybrid Tea "Betty," a variety with very long shell-like petals of salmon-pink colour, and vigorous, smooth-looking leaves. Both varieties were shown by Messrs. A. DICKSON & SONS.

An Award of Merit was also given to a pink Polyantha or Rambler variety named Mrs. F. W. Flight, shown by Messrs. W. CUTBUSH & SONS, Highgate. Other seedlings were exhibited.

MEDAL ROSES.

Amateurs.—The best H.P. was the variety Ulster, shown by E. B. LINDSELL, Esq. The best H.T., was Bessie Brown, shown by A. TATE, Esq.; and the best Tea was White Maman Cochet, shown by the Rev. F. R. BURNSIDE.

Nurserymen.—The best H.P. was the variety A. K. Williams, in the epergne staged by Messrs. E. CANT & SONS, Colchester. The best H.T. was J. B. Clark, a bright crimson-coloured variety exhibited last year; it was shown on this occasion with leaves 4 inches or more across, and 6 inches long, and the flower was quite 5 inches in diameter. This bloom was the most remarkable single item in the show. It belonged to Mr. HUGH DICKSON, Belfast. The best Tea was White Maman Cochet, shown by Messrs. FRANK CANT & CO., Colchester.

Obituary.

M. HENRI DUVAL. — We greatly regret to have to announce the death at Versailles, on June 29, in his thirty-fifth year of this gentleman. Deep sympathy will be felt with his father and the members of his family, who are well known to horticulturists in this country.

GEORGE CROUCHER.—We regret to record the death of this well-known gardener at Ochertyre, near Crieff. Mr. Croucher had been in failing health for many months past, and died on Tuesday, June 27, in his seventy-second year. Deceased was a native of Dunbar, and served his apprenticeship as a gardener in Edinburgh. After his apprenticeship, he entered the service of the late Sir William Keith Murray, Bart., of Ochertyre (father of the present Baronet), in the late fifties, and there he had remained for a period of forty-eight years, having proved himself a highly skilful gardener.

He was a man gifted with a large measure of general intelligence, and devoted himself to a thorough study of horticulture as well as arboriculture, and it always gave him the greatest pleasure to diffuse his knowledge amongst others, as his numerous contributions to these pages testify. He was well versed in matters pertaining to forestry. The collection of Coniferae at Ochertyre was one of the finest in the country, and at the Forestry Exhibition held in Edinburgh in 1884, he was awarded a special honour for a collection of over 150 varieties exhibited from that estate. Mr. Croucher is survived by a widow and grown-up family.

H. H. ORCHARD.—The many gardening friends of Mr. C. Orchard, of Beubridge, I.W., will regret to learn of the death, by drowning in the sea, on July 1, of his nephew, Herbert Henry Orchard, who some three years ago was elected to receive the benefits of the Royal Gardeners' Orphan Fund.

PLANT NOTES.

EXACUM ZEYLANICUM.

THIS is one of the most beautiful blue flowers for the warm greenhouse, but its culture has not been successfully carried out in the greater part of the cases where it has been attempted. Mr. Arthur Dye, gr. to the Right Hon. Lord Rothschild, Triog Park, Tring, has succeeded in growing a fine batch, which are now stout, bushy plants a foot or so across, and densely set with beautiful, star-shaped, violet-blue flowers. Mr. Dye has grown some from cuttings taken and struck when the old plants are in bloom for the next year's flowering, but the greater proportion of

those now in bloom are from seeds part of them saved from plants which flowered last season, and part from seeds imported from Ceylon. The trouble takes place while the plants are small. When they are potted into the flowering-size pots, they do not die, as they often do, without any visible cause, when in the smaller stage. Few blue flowers can surpass those of *Exacum zeylanicum*, and to obtain a good show of them is well worth the care required. There are two forms at Tring Park, the one with the smaller flowers being dwarfier than the other. It is generally named *E. macranthum* in gardens. J. O'B.

MARKETS.

COVENT GARDEN, July 5.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. En.]

* * * EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

CALCEOLARIA: *J. H. P.* The flowers are very pretty, but we believe there are as good varieties already in commerce. Send examples to a trade grower for comparison.

CANTERBURY BELL ON FOXGLOVE: *H. E. H.* The flowers you describe as being Canterbury Bells are merely Foxglove flowers in a state of Peloria, that is, they have become "regular" in development, whereas, generally, the Foxglove develops irregularly and forms an irregular flower. It is not uncommon.

CATERPILLARS: *Boy Myrtle.* In the absence of the perfect insect we can at present only say that the caterpillars in question are those of a species of Tortrix-moth; but we will endeavour to rear the insect, and if successful will give you the name in a later issue.

CUCUMBER: *F. W. P.* A very bad case of eelworm at the roots. Turn out the soil, get fresh soil, and bake it or otherwise sterilise it before use.

CUCUMBER-LEAVES: *A. A. W.* There is no "spot fungus" on your leaves. The appearances point to excessive or too rapid feeding, and consequent indigestion. Very likely fungus may appear eventually. Watch your plants, and send us further specimens later on.—*S. B.* Your plants are affected with spot-disease. Try damping the paths with a weak solution of carbolic acid before shutting up at night.

FLOWERS FOR WINTER AND SPRING: *Reader.* To answer your questions would necessitate more time than is at our disposal. You will find what you require in the *Calendar of Garden Operations*, price 7½d. post free from our Publishing department. There is a note on Sweet Peas in the same work, with an illustration of these flowers growing under glass.

FRUIT: *Kentia.* *Fritillaria imperialis.*

FUMIGATING WITH POTASSIUM CYANIDE: *Fumigant.* You will find detailed accounts in our issues for April 23, and May 21, 1904. The proportions recommended for killing fly and other insects on growing plants per 1,000 feet unit is:—1½ ounce sodium cyanide, 3½ fluid ounces sulphuric acid, 10½ fluid ounces water. The foliage of the plants should be dry and the temperature of the house not above 55°. The exposure should be for forty minutes. CAUTION. The vapours are highly poisonous, and extreme caution on the part of the operator is necessary.

GRAPES: *A. J. M.* Your leaves show numerous young mealy-bug, thrips, red-spider, and other abominations, and the berries show signs of the spot-disease. Try again another year, and be more watchful. Clear out the house as you suggest.

ICELAND Poppies: *H. W.* Double flowers are not uncommon, but yours are unusually good.

IVY: *C. E. L.* Generally speaking a tree is the better for having been cleared of Ivy, and rarely suffers injury in consequence. If you think, however, that the trunk of the tree has been covered so thickly and for so long a time that injury might follow the total removal of Ivy therefrom, you should take away a little only at one time, commencing at the top, and thus gradually remove it all.

MADRESFIELD COURT GRAPE: *M. B., Dunstable.* See Mr. Jordan's remarks in the weekly Calendar in last issue, p. 8, column 1.

MELONS AND VINES: *P. T.* Your plants seem in a bad way. There are eelworms in the roots of the Melons, and mites on the Vines. More cleanly and more careful cultivation is desirable.

NAMES OF PLANTS: *W. G. S.* *Iris ochroleuca.*—*T. F. F.* *Campanula glomerata.*—*Perennial.* *Asphodelus ramosus.*—*T. R.* 1, *Sedum rupestre*; 2, *Geranium sanguineum*; 3, *Melittis melissophyllum*; 4, *Campanula Portenschlagiana*; 5, *Sedum glaucum*; 6, *Acantholimon glumaceum.*—*A. P.* 1, *Calycanthus floridus*; 2, *Ruellia Portellæ*; 3, *Ornithogalum.*—*Lord K.* Owing to the heat the flowers of the Rose had perished, but on comparing the wood, foliage, and habit of flowering with living plants, we believe the variety to be that known as Queen of the Belgians.—*J. S. & Co.* *Cedrus atlantica glauca*, probably.—*A. T.* 1, *Galega officinalis*; 2, *Lychnis chalcidonica*; 3, *Polemonium coruleum*; 4, *Asplenium bulbiferum*; 5, *Adiantum*; 6, *Mesembryanthemum falcatum*; 7, 8, labels detached—one is *Pteris cretica*, the

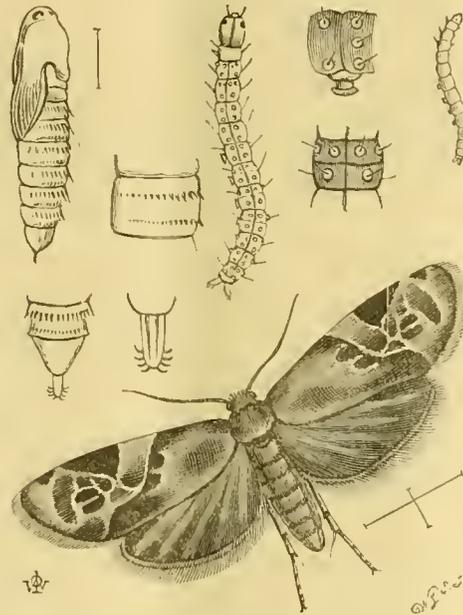

FIG. 16.—TORTRIX ANGSTIORANA, THE VINE MOTH.

other is an *Adiantum.*—*P. & S.* 1, *Syringa Emodi*; 2, *Polygonum cuspidatum.*—*V. I. R.* 1, *Miltonia Russeliana*; 2, *Pleurothallis ornata*; 3, *Stelis micrantha*; 4, *Gongora atropurpurea.* *Novice.* 1, *Lælia tenebrosa*; 2, *Miltonia vexillaria*; 3, *Dendrobium fimbriatum oculatum.*—*F. B.* *Sprekelia formosissima* (*Jacobæa Lily*), an *Amaryllid.*—*Trifolium.* Alsike Clover, a hybrid form much cultivated, and not true *T. pratense.*—*A. G. S.* 1, *Mesembryanthemum Browni*; 2, *Saxifraga Aizoon*; 3, *S. muscoides var. pygmaea*; 4, *S. aizoides*; 5, *Arabis carduchorum*; 6, *Alyssum argenteum.*—*M. W.* 1, *Hedera canariensis*, arborescent form; 2, *Centranthus ruber*; 3, *Sidalcea candida*; 4, *Agrostemma coronaria alba*; 5, *Hemerocallis fulva*; 6, *Juniperus virginiana variegata.*—*A Reader.* *Hieracium aurantiacum.*—*Vitis.* *Deutzia scabra.*

PEACH STONE SPLITTING: *C. B.* A small caterpillar of the Plum Tortrix, similar to that figured in the case of the Vine (fig. 16), was present in your fruit, but we doubt if this was the original cause of the stone splitting. Kindly send another specimen (not over-ripe), and we will investigate further.

PEACH-TREE: *E. H., Tooting.* A minute fungus, *Gloeosporium*, is the cause of the mischief. Infection took place during the flowering stage,

and was probably brought about by insects depositing spores on the stigma when fertilising the flowers. There is no danger of the disease spreading to fruit that has set. Diseased fruit should be collected and burned.

PEACHES: *H. B.* Your fruits are attacked with mildew. Burn the affected fruits, and dust the remaining with flowers-of-sulphur. The caterpillar attacking the Grapes is that of a moth, *Tortrix angustiorana* (see fig. 16).—*Vitis.* The appearances suggest a check from some cause, probably fungus.

PEAS DISEASED: *C. C.* We find traces of fungus, which will probably prove to be the Pea-mildew. Cold, wet weather such as we have recently experienced tends to favour the development of this disease. Overcrowding the rows is a common cause of the fungus obtaining a footing.

POEM: *A. W. S.* We cannot undertake to translate this into modern English.

PTERIS: *W. B.* This form of Pteris, both in the plain and the crested forms, are specially liable to become brown in patches like the specimen you send. Condensed moisture often causes similar damage. The plant received is *Campanula rotundifolia* Hostii.

RHODODENDRONS: *A. M. P.* The young growth has either been frosted, or scorched by the sun shining on the leaves when wet. We have seen the same mischief elsewhere.

ROSES: *A. S. and H. M.* Send to some nurseryman who grows Roses. We do not undertake to name Roses, or florists' flowers of any description.

SCALE INSECTS ON PEACH-TREE AND ROSE-BUSH: *A. S.* The species is the common Peach-scale, *Lecanium persicae.* It occurs on various kinds of plants, but it is most destructive to the Peach when grown under glass. It is, however, by no means scarce on the Peach in the open-air. The paraffin and soap emulsion is the best remedy for this pest. It should be applied in the late autumn or early spring, and the trees should be unnailed.

SEAFORTHIA: *R. P.* We have seen this in flower at Kew, and do not think it is very rare. If the flowers are properly set you might get ripe fruits.

SILVER FIR: *Vitis.* The bark is covered with a coccus allied to the mealy-bug. Scrub with soft-soap to which petroleum has been added in the proportion of a wineglassful to a gallon.

SWEET MAIZE: *E. G. C.* The cobs are as good as could be expected out-of-doors in this climate, unless in exceptional situations. You did quite right in removing the male blossoms.

SWEET PEAS: *S. D. & Son.* The trouble appears to begin in the roots, as if the soil were not suitable; but [without further particulars we can form no idea of the reason the plants go off.

TOMATOS: *M. N. R.* The plants will not be injured by mild fumigation, which we suppose you find necessary to destroy the white-fly, a common pest on Tomatos. We would point out, however, that it will be better to fumigate very mildly, and repeat the process rather than make a severe application. If the plants are growing in pots or in a border composed of very porous soil, they will need frequent saturations with water, and occasionally with manure-water, after the fruits have commenced to swell.

VINES: *A. B.* The leaves are attacked with thrip. As you cannot syringe the Vines, fumigate them with XL-All.

WALLFLOWERS: *Plena.* Pots measuring 5 or 6 inches in diameter should be ample.

COMMUNICATION RECEIVED.—*G. R. S., Boston*—*A. Cogniaux, Nivelles*—*M. de Lairese, Sclessin*—*R. P.*—*H. J. V.*—*H. L. B.*—*Sander et Fils, Bruges*—*W. J. W.*—*Crystal Palace Co.*—*T. R. P.*—*L. J. AN UNDERCLIFF GARDEN.

AT midsummer I had the opportunity of visiting the extremely interesting gardens at Belvedere, St. Lawrence, Isle of Wight, the property of Mrs. M. Gwytherne-Williams. Being well acquainted with the gardens of the south-west counties, I found many plants that do well in the open in South Devon and Cornwall, but several others I had never met with before without glass protection.

The garden is especially rich in Cactaceous plants, the crannies and fissures in the out-crops of rock, that here and there rise above the ground level to a height of some feet, affording ideal sites for plants of this nature. All appeared in the best of health, and amongst them I noticed Agave Victoria Regina, which had been out for five years; Opuntia Salmiana, O. Rafinesquii, O. humilis, O. arborescens, O. xanthostema rosea, and O. glauca, with leaves 15 inches across; Cereus peruvianus, making strong growth; C. flagelliformis, Mammillaria centricirra, bearing coral-red flower-heads; M. missouriensis, Echinopsis Zuccariniana in flower; E. Eyriesii in bud; Gasteria verrucosa in flower, and numerous other plants of the same class. Kniphofia Northii was bearing a flower-spike over 5 feet in height.

The Mesembryanthemums were a glorious sight, painting the rocks with sheets of

vivid colour. Of flowering shrubs, those in bloom included Audibertia grandiflora, Borenia heterophylla, several nice bushes of Bouvardia triphylla, masses of scarlet, and B. Alfred Neuner, 4 feet in height, coming into flower (these had been out for five years); Buddleia Colvilei, 12 feet in height, past its best; Callistemon salignus, Coronilla varia, with pink flowers; Clanthus puniceus, as a bush, still blooming; Diosma gracilis, Elaeocarpus reticulatus, Eriostemon buxifolium, Habrothamnus (Cestrum) elegans, Illicium religiosum, Lavatera assurgentifolia, Leptospermum scoparium, Ozothamnus rosmarinifolius, Polygala oppositifolia, Solanum aviculare, Sophora vicifolia, Sparmannia africana, and Sutherlandia frutescens just going out of bloom. Among other shrubs and trees were Acacia armata, A. Drummondii, A. retinoides, A. verticillata, Abelia lobata, Bowkeria triphylla from South Africa, 10 feet in height, covered with bud; the New Zealand Brachyglottis repanda, Buddleia insignis, B. variabilis 16 feet high, the South American Casalpinia (Poinciana) Gilliesii, a fine shrub of Cantua dependens from Peru, 6 feet in height, planted in front of a 3-foot wall (this had flowered well and was bearing seed-pods); Capparis montana from the Algerian mountains, bearing flowers like a small single Pæony; Cassia corymbosa from Buenos Ayres (in bush form), C. floribunda, Citharexylum barbinerve, Cephalanthus occidentalis (the American Button-wood), Datura sanguinea from Peru, which flowers until Christmas; Desfontainea spinosa, a Chilean, Holly-like shrub; Desmodium penduliflorum, Diosma ericoides, Distylium racemosum, Dodonea multijuga, Edwardsia (Sophora) microphylla, Embotrium coccineum, a most brilliantly-flowered tree often met with in the south-west; Escallonia suspensa, the Mexican Fendlera rupicola, which flowered freely at the end of May; Feijoa Sellowiana from Brazil, Freylinia cestroides from South Africa, Fuchsia syringifolia, Gardenia globosa, which had passed through one winter; the New Zealand Hakea suaveolens, the Cape Bush-Honeysuckle, Halleria lucida, Halesia hispida, Hedyсарum multijugum, Hovenia dulcis, the Australian Hypocalymma robustum bearing pink flowers, Kunzea peduncularis, 6 feet in height; Lagerstromia indica, a healthy bush 4 feet in height and 5 feet through; Lagunaria Patersoni, 6 feet high, from Norfolk Island; the Cape Silver Tree, Leucadendron argenteum, the well-known Brazilian greenhouse plant, Libonia floribunda, 4 feet across; Medicago arborea, Melaleuca densa, Myrsine semiserrata, Nerium Oleander, the New Zealand pink Broom, Notospartium Carmichaeliae, Osteomeles anthyllidifolia, from the Pacific Islands; Ostryopsis Davidiana, 5 feet in height, which bore yellow flowers as large as florins earlier in the year; Perowskia atriplicifolia, Philesia buxifolia, Pterocarya sorbifolia, Rhabdithamnus Solandri, Shepherdia argentea, Solanum crispum, an immense bush by a trellis; Strophanthus capensis, the Chilean Tricuspidaria dependens, better known as Crinodendron Hookeri, and Veronica Hendersoni variegata. Of climbers, Clematis Nellie Moser was blooming superbly on the house, where Actinidia arguta and Swainsonia galegifolia alba were also in flower; Mandevilla suaveolens was showing bud, and Tacsonia exoniensis was growing strongly. In the garden Mutisia

decurrens had several healthy buds; Manettia bicolor was in flower, and among other climbers were Oxera pulchella, Rhodochiton volubile, here a perennial; Lonicera Hildebrandti, L. tatarica, Dioclea glycinoides, Plumbago capensis, Lasiandra (Pleroma) macrantha, Pueraria Thunbergiana, Brachysema acuminata, Ipomoea (Exogonium) purga, I. rubro-cerulea, Hydrangea scandens, and Lapagerias. A very pretty effect was produced by Polygonum Baldschanicum and Rose Euphrosyne, both in full bloom, covering a trellis and archway, while immediately behind a great plant of Crimson Rambler towered some feet higher. A small stream, that runs through its entire length, adds greatly to the attractions of the garden. Close by a little fall in a shady spot is growing the Elk's-horn Fern, Platycerium alcorni, which has been out three winters; and not far distant is a fine plant of the greenhouse Cyrtidium insigne that flowers finely, and in another portion of the garden a group of the lovely Bletia hyacinthina was in full bloom.

Among other noteworthy plants were Amphererepis albescens in flower, Aquilegia ecalcarata (a very old Columbine with spurless blossoms), Astilbe Davidi (fine), Asclepias Douglasi, Asparagus Sprengeri (which had been out seven years, in robust health), the rarely-seen Campanula punctata, many fine, large plants of Cineraria stellata in full flower, which had been out all the winter without protection; Clivia miniata, numbers of Cyclamen persicum on a sloping bank in the best of health, one corm having perfected 200 flowers during the past spring; Digitalis obscurus, from Granada; Erythraea Massoni, bearing its pink flowers; Erythrina crista-galli "Marie Bellanger," an improvement on the type; Ferula gigantea, the brilliant-flowered Gerbera Jamesoni, Incarvillea Olga, Kitabelia vitifolia, 6 feet in height; Leouotis Leonurus, over 3 feet high; Ligularia macrophylla, Liliium giganteum, with many tall spikes, in a sheltered nook; Limoniastrum Guyonianum, a native of the Sahara about Biskra, bearing rosy-mauve flowers, which has been out two winters; Lobelia laxiflora syn. Siphocampylus bicolor; L. Tupa, from Chili; Megacaryon orientale, Micromeria graeca, a little subshrub, whose leaves, when bruised, emit an ammonia-like aroma; Mulgedium (Lactuca) Bourgaei, 6 feet in height; Myrosma cannaefolia, Ostrowskia magnifica, Pentstemon glaber, P. cordifolium, P. tubiflorum, a pretty species 2½ feet high, bearing white flowers; Putoria calabrica on the rocks; Romneya Coulteri, 6 feet by 6 feet; Salvia dichroa, from the Atlas Mountains, in full bloom, with hundreds of long blue-and-white flower-spikes, one of the sights of the garden, a single plant being 8 feet in height and nearly as much through; Tricyrtis hirta, Tulbaghia violacea, bearing its lavender-pink flower-heads; Veratrum nigrum in bud, Witsenia corymbosa, from the Himalayas, bearing blue flowers; and a small plant of Yucca elephantinis, put out this spring.

Of bulbous plants, Brodiaea laxa was in full bloom, as was Trichonema speciosum. Freesias, Ixias, Sparaxis, Babianas and Tritoma were present in quantity, Brunsvigia gigantea and B. Josephinae were in the best of health, as were many hybrid Hippeastrums; and numbers of self-sown seedlings were springing up around a colony of

Pancratium illyricum. Other bulbs included *Cyrtanthus McKenni*, *C. sanguinea*, *Cummingia campanulata*, from Chili, the Californian *Chlorogalum Pomeridianum*, *Ismene Macleayana* from Lima, *Eucomis pallidiflora*, *Calla Elliotiana* and *C. Pentlandi*.

In a small ornamental pool in front of the house some of the best Water-Lilies were in full bloom, the yellow *Nymphaea Marliacea sulphurea* being very fine and large, far surpassing *N. M. chromatella* close by. That the gardens at Belvedere are eminently adapted for the cultivation of rare and tender plants is proved by the grand collection of these that is to be found there in the best of health, but with the sea at the base of its southern slope and the sudden rise of perpendicular cliffs effectually protecting it on the north, it is little wonder that the climatic conditions are favourable. *S. W. Fitzherbert.*

NEW OR NOTEWORTHY PLANTS.

PRIMULA TANGUTICA, DUTHIE.*

This very remarkable-looking *Primula* was originally discovered in 1880 by Przewalski in the Kansu province of Western China. It was regarded by Maximowicz as a variety of Regel's *P. Maximowiczii*, and was named by him "var. *tangutica*," but this name does not appear to have been published. It has recently been found by Mr. E. H. Wilson on the mountains of Szechuan, growing abundantly in open grassy places at elevations between 11,000 and 13,000 feet above the sea. In Przewalski's specimens the flowers seem to vary in colour from pale yellow to the very dark tint as seen in the plants raised by Messrs. Veitch & Sons from the seeds collected by Wilson. It differs from *P. Maximowiczii* by its longer calyx-lobes, and by the very narrow ligulate lobes of the corolla. The flowers have a strong scent, resembling that of *Jasminum Sambac*. *J. F. Duthie, Kew.*

SPECIES OF CHAMÆDOREA WITH PINNATE LEAVES.

THERE are two distinct groups of species of *Chamædorea* with pinnatisect leaves—viz., a small one with aggregated segments, and a larger one whose segments are not aggregated. The former group contains the species *C. glaucifolia*, *C. elegantissima*, and *C. Klotzschiana*. These three species may be easily distinguished without seeing their flowers and fruits. *C. glaucifolia* and *C. elegantissima* have very small segments, not more than six lines broad, whilst the segments of *C. Klotzschiana* are 2 to 4 inches in breadth. *C. glaucifolia*, one of the most graceful of all species, has leaves with 75 to 80 glaucous segments; *C. elegantissima*, on the contrary, has 30 to 36 bright green segments in each leaf. All the other species of *Chamædorea* have non-aggregate seg-

* *Primula tangutica*, Duthie.—Rootstock short, stout. Leaves all radical, fleshy, glabrous, 2–4½ in. long and ¾–1 in. broad, narrowly oblanceolate, rounded or abruptly acuminate at the apex, tapering downwards into the winged petiole, finely denticulate along the margins of the upper half, midrib stout, lateral veins obscure. Scape 1–3 ft. high, stout, glabrous except just below the flowers. Flowers whorled, drooping, 5–9 in a whorl. Bracts narrowly subulate, shorter than the pedicels, deeply channelled above, pubescent. Pedicels ¼–½ in. long, puberulous. Calyx shorter than the corolla-tube, glabrous outside, puberulous within, divided ½–¾-way down into narrowly subulate somewhat unequal segments, the margins minutely denticulate. Corolla ½ in. across, varying from yellow to dark chocolate or almost black; tube ¾ in. long in the long-styled form, and ¾ in. in the short-styled form, tinged with crimson, the mouth surrounded by a 5 gonal ridge; lobes reflexed, narrowly ligulate, obtuse.

ments. Only one of them is distinguished from the others by its segments being strongly reflexed in the leaves of adult specimens, *C. scandens*,

C. scandens bambusoides, Wendland, which is remarkable for vigorous lateral shoots issuing from the stem several feet above the ground.

FIG. 17.—PRIMULA TANGUTICA: FLOWERS DEEP PURPLE. Section of flower twice magnified; pollen-grains magnified 400 diam.

Wendl.; of this Wendland distinguished five varieties. The best known of these is *C. scandens* var. *desmoncoides*, Wendl., well known in gardens as *C. desmoncoides*, which grows up to about 60 ft. in height. Another newly-introduced variety is

Amongst the species with spreading or erect segments only two have linear segments—*C. graminifolia* with thick stems, and *C. Klotzschiana* with thin stems, and with segments half the size of those of the former, viz., 2 to 3 lines broad.

The segments of the other species are lanceolate, oblong-lanceolate, or elliptical. A few of these, viz. *C. costaricana*, *C. elatior*, *C. elongata*, and *C. inaequilateralis*, have leaves the segments of which are almost imbricate, so closely are they set. Of these four species *C. costaricana* has only 18 to 20 segments on each side of the rachis, whilst the others have more than 20 segments on each side. Of these three *C. elatior* has segments not longer than a foot; the segments of the two others are longer than this; they are distinguished by the

the large mass of other species is not so readily defined. I have had much trouble in making a classification that might enable the gardener to determine a given species without seeing its flowers and fruits. Of course, the scheme adopted must be quite an artificial one; closely allied species are separated, and remotely affiliated ones are brought near together. But I thought it better to give a scheme that would be practically useful to everyone rather than a scientific one, which can be employed only when

will consider first those with 3 to 10 segments. Of these about half have the segments only 2 to 4 times as long as they are broad, whilst the segments of the other half are more than 4 times as long as broad. Of those 2 to 4 times longer than broad, *C. concolor* and *C. brevifrons* have segments 15 to 23 cm. (6 to 9 inches) long; *C. concolor* has 5 to 6 segments on each side of the rachis, *C. brevifrons* 6 to 8 segments. The segments of the other species of the broad-segmented group are 25 to 50 cm. (10 to 20 inches) long. Of these *C. bracteata* has on each side of the rachis 4 to 6 segments; *C. oblongata*, *C. lunata*, and *C. homomalla* have 5 to 7 segments on each side of the rachis; and *C. flavovirens* and *C. alternans* have 6 to 8 segments on each side. The three former species are distinguished by the number of the veins of each segment, the two first plants having only 3-nerved segments, *C. homomalla* 7 to 9-nerved segments. I cannot find any difference between the leaves of *C. oblongata* and *lunata*, but they are distinguished by their male inflorescences, *C. oblongata* having thicker, *C. lunata* thinner rami of the male inflorescence. The two species, *C. flavovirens* and *C. alternans* are easily distinguished; *C. flavovirens* having segments 7 to 9 cm. (about 3 to 4 inches) broad, whilst the segments of *C. alternans* are 11 to 14 cm. broad ($4\frac{1}{4}$ to $5\frac{3}{4}$ inches).

In the group with segments more than four times longer than broad, five species have segments not longer than 18 cm. ($7\frac{1}{4}$ inches), whilst seven species have longer segments. Of the short segmented ones, two species, *C. pygmaea* and *C. Donnell-Smithii*, have segments which are not broader than 1.5 cm. ($\frac{1}{2}$ inch); *C. pygmaea* having 6 to 8 segments on each side of the rachis; *C. Donnell-Smithii*, the most dwarf Palm hitherto known, being only a few inches high, has only 2 to 4 segments on each side of the rachis. The three other species of this group with segments not longer than $7\frac{1}{4}$ inches are distinguished by the number of veins in the segments: *C. bifurcata* having 3-nerved, *C. variabilis* 5-nerved, *C. microphylla* 9-nerved segments.

Of the group with segments longer than $7\frac{1}{4}$ inches we may distinguish three species—viz., *C. Pacaya*, *C. Bartlingiana*, and *C. pinnatifrons*—from the other four by their having segments not longer than a foot, whilst the segments of the four latter are longer. *C. Pacaya* has segments not broader than 4 cm. (nearly 2 inches), whilst those of the two others are at least that width. *C. Bartlingiana* has 5 to 6 segments on each side of the rachis; *C. pinnatifrons* 8 to 10 segments on each side of the rachis. The species with segments longer than 30 cm. (a foot) are *C. paradoxa*, *C. lanceolata*, *C. Sartori*, and *C. Casperiana*. Of these, *C. paradoxa* and *C. lanceolata* have 3-nerved segments, *C. Sartori* has 5-nerved segments, and *C. Casperiana* 9 to 10-nerved segments. The two 3-nerved species are easily distinguishable, *C. paradoxa* having segments 4 to 5 cm. ($1\frac{3}{4}$ to 2 inches) broad, whilst those of *C. lanceolata* are 6 to 7 cm. broad ($2\frac{1}{4}$ to $2\frac{3}{4}$ inches).

We have still to consider those species of *Chamædorea* with non-aggregate, spreading, or erect-spreading lanceolate, oblong-lanceolate or elliptical remote, not decurrent segments, which have 10 to 30 segments on each side of the rachis. Of these we may distinguish two groups: one large one comprising all those with 10 to 22 segments on each side of the rachis, and another smaller one with Palms having more than 22 segments on each side of the rachis. Of the former group (10 to 22 segments) we distinguish those with segments not broader than 5 cm. (2 inches), from those whose segments are broader. Of those whose segments are not broader than 5 cm., five species have not more than 15 segments on each side of the rachis, whilst four have from 15 to 22 segments. The five first may be classed

FIG. 18.—MESSRS. LAXTON'S NEW STRAWBERRY "BEDFORD CHAMPION."

From a cross between a seedling from Noble x Sir Joseph Paxton, and a seedling from Scarlet Queen and John Ruskin. (See description on pp. 11 and 34.)

breadth of their segments; those of *C. elongata* are 1 to $1\frac{1}{2}$ inch broad, those of *C. inaequilateralis* are $1\frac{3}{8}$ to $1\frac{1}{2}$ inch.

Of the species with remote segments three are easily recognisable by their decurrent segments—*C. cataractarum*, *C. Martiana*, and *C. brachyclada*. The differences between these three species are the following:—*C. cataractarum* has very small segments, only 0.8 to 1.3 cm. broad (about $\frac{1}{4}$ to $\frac{1}{2}$ inch); those of the two others are 2 to 2.6 cm. broad (nearly an inch); but in *C. Martiana* are 3-nerved; but in *C. brachyclada* 5-nerved.

Whilst the foregoing twelve species, according to the grouping given, are easily distinguishable,

the plants are in flower. There are two characteristics of great constancy peculiar to the species: the number of segments on each side of the rachis, and the number of veins in each segment. Well-marked characteristics are also the relations between the length and breadth of the segments and the height of the segments. In all cases, of course, the characteristics mentioned are taken from leaves of full-grown specimens. We make thus two groups: one including all those species whose leaves have 3 to 10 segments on each side of the rachis, and another whose leaves have 10 to 30 segments on each side of the rachis. These two groups are nearly equal in number; the former includes twenty, the other fifteen species. We

with those with segments not broader than 3 cm. ($1\frac{1}{2}$ inch) and those with segments 4 to 5 cm. broad ($1\frac{3}{8}$ to 2 inches). The species with narrow segments are *C. Galeottiana*, *C. radicalis*, both with segments not longer than 25 cm. (10 inches), and *C. oreophila* with segments up to 33 cm. long (13 $\frac{1}{2}$ inches). *C. Galeottiana* has 1-nerved, *C. radicalis* 3 to 5-nerved segments. Of the two species with wider segments, *C. Schiedeana* has segments 20 to 35 cm. long (8 to 14 inches), whilst *C. macrospadix* has segments 40 to 45 cm. long (16 to 18 inches).

The second group, with segments not broader than 5 cm. (2 inches) but with more than 15 segments on each side of the rachis, contains *C. brachyclada*, *C. elegans*, *C. Liebmanni*, and *C. corallina*. Of these, *C. brachyclada* has segments 2 to 3 cm. broad ($\frac{3}{8}$ to $1\frac{1}{8}$ inch), *C. elegans* and *C. Liebmanni* segments 3 to 4.5 cm. broad ($1\frac{1}{8}$ to nearly 2 inches), and *C. corallina* segments 5 cm. (2 inches) broad. *C. elegans* is distinguished from *C. Liebmanni* by having a full leafy crown, whose fronds have about 20 segments on each side of the rachis, whilst *C. Liebmanni* has a crown of only 4 to 6 leaves, which have only some 15 segments on each side of the rachis.

The species with 10 to 22 segments on each side of the leaf-rachis, whose segments are broader than 5 cm. (2 inches), are *C. Wendlandiana* with 5-nerved segments, *C. Tepejilote* with 7-nerved segments, and *C. exorrhiza* with 9-nerved segments.

Now we have only those three species to consider which have more than 22 segments on each side of the rachis. Of these, *C. montana* has segments only up to 3 cm. ($1\frac{1}{8}$ inch) broad, whilst those of *C. Poeppigiana* and *C. fragrans* are broader. *C. Poeppigiana* has dark-green leaves with segments 4 to 5 cm. ($1\frac{3}{8}$ to 2 inches) broad, whilst *C. fragrans* has bright-green leaves with segments 5 to 6 cm. (2 to $2\frac{1}{8}$ inches) broad.

It will be easy for the gardener to make for himself a key from the above short notes, which will enable him to determine at once the species of *Chamaedorea* he has in cultivation, even when they are not in flower. There are amongst the above-named species a good many not yet described, though they have been for some long time in cultivation. Full descriptions of them will be found in my monograph of the genus *Chamaedorea*, which will be published shortly. For the new species where no authority is mentioned Hermann Wendland is always the authority.

I have still a few words to say about the limitations of the genus. The species here named are reckoned by some authors as belonging in part to the genus *Morenia* and *Kunthia*. But as there are no differentiating characteristics in these genera I include them with *Chamaedorea*, contrary to Wendland and to the principles of priority. Wendland found that *Kunthia* is by no means the only monoecious species, and that the somewhat mysterious *K. montana* is the same as *C. Lindeniana* or *Morenia Lindeniana*. Both these latter names must be given up and the plant named *Chamaedorea montana*. The genus *Morenia* has this chief characteristic, that the male inflorescences stand in groups on each ring of the stem. But Wendland showed that this characteristic is also to be sometimes met with in species of *Chamaedorea*. Now *Morenia* is the older name, and therefore, says Wendland, all species of *Chamaedorea* must be re-named *Morenia*. But if you wish to separate *Morenia* from *Chamaedorea* the name *Chamaedorea* must not be adopted according to the principles of priority, as there are still two other names that have precedence in *Nunnezia* and *Nunnezharia*. Even *Martinezia* is a name which may come into consideration. But I think it is better from a practical standpoint to preserve the

well-known name *Chamaedorea* and to reject all the other names. It would cause too much trouble in practice if the name *Chamaedorea* disappeared and one of the above-mentioned names took its place. In his manuscript Wendland wrote *Morenia*, but he always spoke of *Chamaedorea*. And so it may rest. Dr. Udo Dammer, Dahlem, Berlin.

THE BERMUDA LILY CULTURE.

The chief industry in Bermuda is Lily farming (*Lilium longiflorum* and the variety *Harrisii*), although the Lily disease has been so prevalent of late years that many farmers have been compelled to give up growing these plants. This disease has given the British Government endless trouble, and nothing has been discovered up to the present that will effectually exterminate the disease, although its ravages have been stopped to a great extent by spraying with Bordeaux-mixture. The ground is cultivated for planting the bulbs in August, after having been allowed to lie fallow during the summer months, although in some cases it is utilised for growing Melons in order to keep the ground free from grass. A few years since the experiment of growing Tobacco for a summer crop was tried, but was soon abandoned, as the growers asserted that the crop took more nourishment from the soil than the Tobacco was worth, and that they had to spend all the money derived from the sale of the Tobacco to purchase manure for the Lilies. In the experimental station nothing but farmyard manure was used when the ground was prepared for Lily culture, and this consisted of as large a proportion of cow manure as possible, as the soil in Bermuda is sandy and porous. The Lilies are propagated by separating the scales from the bulb, and placing these in drills at a depth of 3 inches, allowing 4 inches between the individual scales. This operation is generally carried out during the first week in September, and by the following June these scales form small bulbs 1 to $1\frac{1}{2}$ inch in circumference, when they are dug up, dried, and stored away in sand until the following September, when they are again planted in the ground in rows drawn 3 inches apart, allowing 2 inches between the bulbs in the rows. After a season's growth they are dug up about June, by which time they are from 3 to 4 inches in circumference. The following season they attain a size of from 5 to 7 inches in circumference, which is the smallest marketable size; and they increase their growth until they reach a size of from 11 to 13 inches in circumference, after which they do not increase in size, but deteriorate and split into bulbils. It is when the bulb starts into growth that the disease puts in its appearance, and it is at this time that spraying operations are conducted. The method of preparing the fungicide is as follows: three fifty-gallon barrels are obtained, one for holding the mixture, and the other two for mixing purposes. In each of the two latter barrels 25 gallons of water are placed; in the one case 4 lb. of copper-sulphate is added, and in the other 6 lb. of quicklime. When the sulphate of copper and the lime have dissolved, the contents of the two barrels are poured at the same time into the stock-barrel, which process insures proper mixing. The mixture is then ready for spraying. It is always better to spray the plants the first thing in the morning and the last thing in the evening. The Lilies are sprayed before there is any appearance of the disease, and also at intervals throughout the growing season.

The farmer, as a rule, sells his bulbs in advance, before he puts them in the ground, there being such a demand for good, true bulbs. When these large growers notice a diseased bulb in their batch, they dig it out and burn it. The experimental station advises, after digging the diseased bulb out, that the vacant place be sprinkled with crushed sulphate of iron, this kills any remaining

spores that may be left in the soil. The small growers, and several of these are Portuguese, mix diseased bulbs with the good ones, and sell to the commission man, who buys his bulbs ready dug up on the ground, and employs men to pack them. These men also mix their bulbs, putting the true variety *Harrisii* and the longiflorum together, and selling the mixture as true *Harrisii*. This is a great disadvantage when forcing the bulbs with the intention of obtaining flowers for Christmas, as the *Harrisii* variety will flower by Christmas, but the longiflorum are a week or two later in flowering. Another great mistake on the farmers' part is to dig up the Lilies before the bulbs are ripe, as unripe bulbs are not fit for forcing. For instance, only last January I went to see some private gardens in Newport, R.I., U.S.A., where they annually force large quantities for Christmas. One Scotch gardener told me that a batch he had just started was diseased, and that his Christmas batch also turned out diseased. I informed him they were not diseased, but unripe, and that they would not stand forcing. I know of several similar cases where unripe bulbs have been pronounced diseased. To conclude, I would advise any who force bulbs to dip them before they are potted into a solution of weak permanganate of potash (Condy's Fluid), this kills the spores of the disease in the bulb. Again, when the Lilies have commenced growing in the pots, spray at intervals with Bordeaux-mixture; the spray leaves a bluish sediment on the foliage. This can be easily removed by syringing with clear water; but allow it to remain on as long as possible. Geo. Chisholm, Llanrust.

COLONIAL NOTES.

PESTS AND THEIR PARASITES.

ACCORDING to a recent return issued by the United States Agricultural Department, the direct and indirect yearly losses caused by insects in that country alone amount in the aggregate to the enormous total of over 700 million dollars (£140,000,000). If to this be added the loss in other lands, the amount must be great indeed. Any wise and energetic effort, therefore, which seeks to reduce the number of these destructive agents and to check their ravages is worthy of the keenest attention on the part especially of men who gain their living from the soil.

It is consequently with some interest that we have heard of the work of Mr. George Compere, the travelling entomologist, whose unique and able services have for some time past been requisitioned by the Governments of Western Australia and California.

Mr. Compere gained his knowledge of fruit-pests and parasites under Mr. Arthur Kobele, who at one time was in the service of the Californian Government, and is now the entomological expert of Hawaii. These insect investigators affirm that every pest has its parasite, as, according to the moralist, every evil has its remedy. So that it is only necessary to follow the pest to its original habitat to find the check which Nature herself has provided for it.

This, then, is Mr. Geo. Compere's work. According to Mr. Despeissis, the head of the Western Australian Horticultural and Viticultural Department, he has to direct his attention almost exclusively towards fighting Nature's pests by Nature's own means. To do this he has to follow the pest to its home in many lands, with the view of discovering the parasite that feeds upon it.

His labours appear to have been crowned already with a very fair measure of success, as he has successfully introduced into Western Australia, from Queensland, parasites of the black scale, the soft brown scale, the Cabbage moth, and the Cabbage aphid, with a ladybird, which

ORCHID NOTES AND GLEANINGS.

ONCIDIUM ROBUSTISSIMUM.

A PHOTOGRAPH of a plant in flower, of a single flower, and living examples of the blooms, sent by H. Emmons, Esq., The Copse, Hamble, Southampton, seems to represent the plant described by the late Professor Reichenbach under the above name in the *Gardeners' Chronicle*, September 29, 1888, p. 352. It is closely allied to *O. pulvinatum*, the characters relied on in the description however being present.

The description states: "This is an uncommonly intricate, critical species. It belongs to the *Pulvinata* section, including *O. divaricatum*, *pulvinatum*, and *sphagiferum*. It is, however, quite distinct at first sight in its strong, straight rachis, the side branches of which are not zigzag at all, but straight, too. The flowers are larger,

FIG. 19.—ONCIDIUM ROBUSTISSIMUM.

and the lip has the anterior part of the blade broad as the lateral ones. The sepals and petals are yellow at the top, brown at the inferior part. The lip has the rounded serrate lateral lacinia, as well as the anterior emarginate one, with broad cinnamon-coloured stripes," &c.

Mr. Emmons describes his plant: "Leaves from 1 foot to 1 foot 4 inches long, olive-green in colour and very thick. Length of spike 6 feet 6 inches, with twenty-five branches ranging from 2 feet 2 inches to a few inches long. The largest branch carried one hundred flowers, and the whole spike seven hundred and sixty blooms, each flower an inch in diameter.

ORCHID ARRANGEMENTS.

The useful side of Orchid culture is generally to be seen in the pretty gardens of Ludwig Mond, Esq., The Poplars, Avenue Road, Regent's Park, London, where effective use is made of the Orchids in bloom at all seasons in the floral arrangements in the temperate conservatory. A fine piece of statuary, beside which are ornamental seats, occupy one end, and around is a permanent arrangement of rockery and cork-faced staging. Palms and Ferns, among which are some good examples of the African *Lomaria Boryana* with tall stout crowns are the permanent plants, and among them various subjects in flower are arranged. At

the highest point there were recently several finely-flowered specimens of *Cypripedium Lowianum*, their long sprays arching gracefully among the other plants. Beneath them are good specimens of *Odontoglossum crispum*, pink Milton *vexillaria*, *Laelia purpurata*, *Cattleya Mossiae*, *C. Mendeli*, *Oncidium sarcoodes*, *O. papilio* and other Orchids.

But the Orchids are not allowed to take undue prominence, and herein lies the great attraction of the arrangement. Effectively displayed among the Orchids are good specimens of the white *Francoa*, scarlet *Anthurium*, large-flowered scarlet and yellow *Cannas*, *Mignonette*, and a few other flowers, while diversity of foliage is given by variously-tinted Japanese Maples, variegated *Vitis heterophylla*, &c.

Many Orchids last a long time in flower, and by this method of arranging them with other plants in bloom as they are available it is easy to get a greater diversity of effect than by arranging the Orchids by themselves. Mr. J. O. Clarke has charge of the garden. J. O'B.

NEGLECTED TIMBER TREES.

THE note by Mr. Simpson, in a recent issue of the *Gardeners' Chronicle*, on the Locust tree, served to call to mind several others which, though passed over by planters, are yet deserving of extensive planting in this country, more especially in those parts where the water level is but a few feet below the surface, therefore in boggy land, in the vicinity of lakes, and sluggish streams, reclaimed fen land, and the like. I will place first, on account of its rapidity of vertical stem growth, i.e., 2 to 3 feet in a season, the *Juglans nigra*, usually called Black Walnut from the dark tint of the heartwood (and in aged trees it is nearly all heartwood). Planters should obtain the nuts from the trade, and preferably from Continental houses dealing in tree seeds, making their purchases early in the winter, and either plant the nuts 4 to 6 inches deep in land suitably prepared, and where they will stand to grow to timber size, or stratify them in cold pits or in frames sunk in the soil where some protection from frost may be afforded them in hard weather, and plant them out where they are to stand in the spring, at which season germination will have begun. Much care must be exercised in the planting, so as not to injure either the root or the cotyledon. As older seedlings do not transplant readily and the plants take several years to recover from injuries caused by removal, sowing the seeds once and for all is to be preferred. Afforded a growing space of from two to three yards apart, the young trees make quick growth, and in a few years shade the soil with their ample foliage, shooting up to a great height with straight, cylindrical smooth stems, which do not usually form branches low down, or if they should do so these soon perish owing to lack of light and air. This species of *Juglans* grows as fast as a common Spruce, a Silver Fir, or a Larch, and in forty years becomes of commercial value.

Another excellent and useful tree is the common Alder, *Alnus glutinosa*, sometimes called the Water Oak from its resemblance in habit when growing with a single stem to an Oak. As the Alders throw out suckers freely, they usually assume the appearance of stooled coppice trees, and seldom reach to any large size. This tendency can only be overcome by rigidly grubbing up the suckers whilst these are still small, and confining the tree to one stem. Needless to say, that, like the Willows and Poplars, the tree does best in moist land, on the banks of rivers and lakes, in which situations growth is rapid; and when the locality is very moist and of any great extent, the plants may be set out at 5 or 6 feet apart, no thinning in after years being then required. Matured timber of

has a strong attachment to the mealy-bug. From Spain and the South of France he has obtained parasites of the Grain moth and the Grape Vine scale, with several useful kinds of ladybirds. In Spain, too, he found the parasite of the Codlin moth, a discovery the value of which to the Californian and Australian fruit-growers, should it prove what is expected of it, cannot be over-estimated.

India, we are told, has much to answer for in breeding insect pests, so that it is satisfactory to note that Mr. Compere has been provided with several efficient parasites from that country. Some of the most efficacious of these prey on the eggs and others attack the fruit fly maggot itself. To India, therefore, Mr. Compere looks as a happy hunting-ground in his search for effective allies in the war with his insect enemies.

But South America also has well repaid the investigations of this explorer. In April of last year he visited Rio de Janeiro, "where," he says, "notwithstanding the large amount of fruit exposed for sale, not a single fruit infested with maggot was noticed, and no trace of fruit fly could be detected." In San Paolo he found a few scattered half-decayed Oranges, some of which showed signs of having once been punctured by fruit flies, but the closest scrutiny failed to reveal any maggots in the decayed fruit. Following up this quest, he interviewed the owner of a local orchard, who stated that during eighteen years in which he had had possession of the orchard he had never noticed any damage to fruits caused by fruit flies; in fact he never knew that there were such insects! However, Mr. Compere eventually found a few small *Ichneumon* flies on some Oranges, apparently in search of infested fruits. Upon these he kept a close watch for some time, and at length discovered one in the act of ovipositing in an Orange. This Orange, as soon as the parasite had finished laying her eggs, he took from the tree, placing it in a jar which he kept in his room. Two days later the fruit fly maggots had completed their growth, and pupated in the bottom of the jar. In due course five parasites and two fruit-flies made their appearance. Further examination in this district led to the discovery of the *Staphylinidæ* beetles, whose capabilities in the destruction of maggots of all kinds appear phenomenal. "Beyond question," he affirms, "these beetles destroy the major part of the fruit-fly maggot in Brazil, and also destroy a large number of the parasites as well, eating every maggot with which they come in contact, not discriminating between those parasited and those that are not."

This year Mr. Compere paid another visit to Brazil, that he might become better acquainted with these beetles, and that he might get a fuller supply than he was able to secure on his first discovery of them. Returning from this journey he passed through London, having with him a number of the beetles, which he was found diligently feeding with blow-flies, for which they have a special avidity. It would seem, according to Mr. Compere, that it is no small matter to find sufficient food to satisfy the rapacious appetites of the *Staphylinidæ*, as in default of other nutriment they develop cannibalistic instincts and feed on each other.

If but a fraction of the claims which Mr. Compere advances on behalf of his various parasites prove well-founded, there is no doubt that they will be of the greatest value to Western Australia and California. The beetles in particular will find a wild field for their operations in the former country not only among the fruit pests, especially those which attack the Orange groves, but among the troops of common and blow-flies which have made their home in that favoured land. *The Agent-General for Western Australia.*

the common Alder, when it can be obtained of sufficiently large dimensions, is much valued for piling and underwater constructions, as sluices, flooring in mill-races, lock-gates, and sills, in which situations it is more durable than Oak.

The common Hornbeam (*Carpinus Betulus*) is another much-neglected timber-tree. A form of this *C. B. incisa* is frequently met with as a garden tree. Planted so as to form close cover, its natural tendency to form a spreading, round-headed tree with much useless lop and top is obviated, and tall, straight, smooth stems are obtained instead. The timber has many uses, and makes the best of firewood for burning on the open hearth or in close stoves, being very close grained, and easily split with the axe. *F. M.*

CAMBRIDGE BOTANIC GARDEN.

The Botanic Garden Syndicate reports to the Senate that two new boilers have been procured (*Reporter*, May 9, p. 843; June 13, 1905, p. 1073).

The Botanic Garden was made use of in providing employment for men in need of work.

During the year 1904, 1,658 plants, 2,359 bulbs, and 4,185 packets of seeds were received, while 1,431 plants and 3,140 packets of seeds were distributed. Contributions were received from nearly sixty botanic gardens.

Among the more interesting plants received are *Allium Ellisii* (*Botanical Magazine*, t. 7875), a fine species from Khorasan of a group wholly Oriental; the wild original of the garden Cyclamen; *Celogyne pandurata*, "one of the most remarkable of Orchids," with large green flowers marked with black; *Gloriosa Rothschildiana* (see *Garden*, June 25, 1904, p. 451), a magnificent new species with crimson flowers from near Lake Victoria Nyanza; *Solanum Commersoni*, a species of Potato from the Argentine Republic, formerly recommended only for forage, but now regarded as suitable for cultivation in wet soils that are ill-adapted for ordinary varieties, said to bear tubers of good flavour rich in nutriment; *Davidia involucreata*, a fine new Chinese Cornaceous plant, originally discovered by the Abbé David in the mountains of Mu-Piu west of Szechuan; *Jasminum primulinum* (*Botanical Magazine*, t. 7981), a new species from Yunnan similar to the winter-flowering *J. nudiflorum*, but finer; *Meconopsis integrifolia*, an exceedingly fine Papaveraceous plant, with yellow flowers from Western China (see *Gardeners' Chronicle*, October 1, 1904, p. 240); *M. aculeata*, a rare blue-flowered species; *Impatiens Oliveri* (*Botanical Magazine*, t. 7960), a new species raised at Kew from seeds obtained by Sir John Kirk along the Uganda railway; *Lysimachia Henryi* (*Botanical Magazine*, t. 7961), originally collected by Dr. Henry near Ichang in the Province of Hupeh in Western China; *Clerodendron myrmecophilum* (*Botanical Magazine*, t. 7887), a new species with handsome flowers, of special interest on account of the swollen internodes inhabited by ants; *Pyrus Niedzwetzkyana* (*Botanical Magazine*, t. 7975), a new ornamental ally of the Apple with exceptional redness throughout the plant; *Lonicera etrusca* var. *superba* (*Botanical Magazine*, t. 7977), recently recorded from the Mediterranean region; *Bryonia alba*, a plant used in medicine, obtained from the Continent, hitherto unrepresented in British gardens; *Iris obtusifolia* (*Botanical Magazine*, t. 7701), a new species from the Province of Mazanderan on the south of the Caspian Sea; *Styrax officinale*, the tree which yields the balsamic resinous substance known as Storax; *Angraecum Eichlerianum*, an interesting species lately introduced from Calabar; *Rhizophora Mangle*, the Mangrove of tropical shores; *Cyatnodes empetrifolia*, a rare New Zealand Epacrid; *Tanakaia radicans* (*Botanical Magazine*, t. 7943), the only species of the genus, a native of Japan, peculiar among Saxifragas in having unisexual flowers; *Trichosanthes japonica*, an addition to the few hardy perennial Cucurbitaceae; *Abies Vilmorini* (*A. Pinsapo* × *A. cephalonica*), one of the few hybrid Conifers (illustrated in the *Gardeners' Chronicle*, 1901, February 9, p. 89).

Among the more interesting of British plants received are *Koeleria valesiaca*, found in the Herbarium of Dillenius at Oxford and recently re-discovered in the original locality at Brent Down in Somersetshire; *Malaxis paludosa*, an interesting Orchid, having its leaves fringed with bulbils capable of producing new plants; *Crocus biflorus*, naturalised in Barton Park, Bury St. Edmunds, where it has maintained its ground for more than a century; *Viola calcarea* (see *Journal of Botany*, March, 1904, p. 67), sent from Cheddar by Mrs. Gregory (formerly regarded as exclusively a Cambridgeshire plant), and recently obtained from the Gogmagogs by the Curator and Mr. Hosking; *Fumaria occidentalis*, sp. nov., of more robust habit than any other British fumitory, found in West Cornwall, and described by Mr. H. W. Pugsley in the *Journal of Botany* (August, 1904,

p. 217); *Erica Tetralix* *β* *Watsoni*, found near Truro; *E. Mackaii*, long known in co. Galway; and *E. Stuarti*, found in Connemara and probably a hybrid, described in the *Annals of Scottish Natural History* (July, 1902, p. 177). *Eriocaulon septangulare*, collected by Mrs. Babington, has flowered freely, and appears to be permanently established.

Sauromatum brevipes has been figured and described in the *Botanical Magazine* from Cambridge material (t. 7940). The examination of the living plant has resulted in its reference to the genus *Sauromatum* instead of to *Typhonium*, in which it was formerly placed in the absence of satisfactory evidence as to the nature of the spathe. In the *Gardeners' Chronicle* (June 18, p. 387) *Hemaria Dawsoniana*, an Orchid with copper-veined leaves and white flowers, was illustrated from a photograph by the indoor foreman, Mr. E. Allard.

Among the plants of special interest that flowered were *Gnidia polystachya*, figured in the *Botanical Magazine*, 1905, t. 8001; *Urginea Wightiana*, an Indian species of Squill used in medicine; *Iris Ascheroni*, a new species allied to *I. Grant-Duffi*; *Bartholina pectinata*, a remarkable Cape Orchid with finely divided labellum; *Acacia sphaerocephala*, the species described by Belt in his *Flora of Nicaragua*, which bears "food bodies," and is characterised by hollow spines inhabited by ants; *Richardia cantabrigiensis*, a hybrid raised by the Curator (R. Reimanni × *melanoleuca*), described in the *Gardeners' Chronicle*, April 9, 1904, p. 226, to be figured in *Flora and Sylva*; *Stapelia* sp. nov.; *Listrostachys Sedeni*, an Orchid from British West Africa, contributed by Mr. Cyril Crossland; and hybrid *Gerberas*, raised by the Curator, to whom a Silver Cup was awarded for an exhibit at the Temple Show. The exhibit was illustrated in *The Garden*, 1904, vol. lxv., p. 405.

Samples of various fibre plants have been supplied to Messrs. Deane & Ellwood, of Leicester, for the purpose of experiments in the development of a fibre-extracting machine.

The number of specimens supplied for botanical purposes during the year amounted to 99,355.

BOOK NOTICE.

HANDBUCH DER PFLANZENKRANKHEITEN, von Prof. Dr. Paul Sorauer. Dritte vollständig neubearbeitete Auflage in Gemeinschaft mit Prof. Dr. G. Lindau und Dr. L. Reh, herausgegeben von Prof. Dr. Paul Sorauer. (Berlin, Paul Parey, 1905.)

The third edition of this handbook of plant diseases differs from the last, as Prof. Sorauer has not undertaken to issue the whole of the book himself, but has secured the services of two specialists for co-operation. The reason for this alteration is to avoid getting out of touch with the abundant material collected since the publication of the second edition, and also in order to make the new edition as perfect as possible. The new work has been divided into three volumes, each of which is being prepared by a specialist in the particular branches. The injuries caused by insects are treated by Dr. L. Reh, the zoologist of the Natural History Museum in Hamburg; diseases caused by plant parasites, fungi, &c., are dealt with by Prof. Dr. G. Lindau, specialist on plant-diseases of the Berlin University; whilst Prof. Sorauer himself prepares the volume dealing with injuries caused by atmospheric conditions, exposure, condition and mechanical properties of soil.

The arrangement of the book according to the causes of diseases is the same as in the second edition, and although it would be undoubtedly easier to ascertain the nature of a malady if the matter were arranged according to host-plants, as for instance in Kirchner's work, a repetition of the nature of the disease would be necessary with each host-plant. But Prof. Sorauer lays the greatest stress upon the scientific explanation, the relation of disease to certain conditions in the life of plants, making them susceptible, and on the true origin of disease. The careful study of these items will enable the reader to form an opinion and to rationally deal with such attacks.

From this point of view every one of the three scientists has based his special subject upon conditions under which disease develops, and points out such circumstances which induce a plant

to take disease, *i.e.*, make a plant susceptible, as conditions of weather, culture, &c. Professor Sorauer, as is probably known, was the first defender of the view that there is a predisposition of plants for disease, and though he stood alone in this theory on the publication of the first edition of his work, it has been recently taken up by eminent investigators. In consequence of this theory, the parasites themselves do not receive exclusive attention, but such important factors as may be responsible for the attack of parasites are also treated on.

Guided by this idea, the third edition of the handbook deals largely with the predisposing or disease-favouring factors, and calls attention to the fact of a relationship of plants to their places of growth and their surroundings, and to the individual development of plants, the conditions of nutrition of which deviate from their natural mode of growth. In consequence, the secret of combating epidemics lies more in the study and prevention of the unnatural conditions than in the method of combating the disease itself, as is the case at present by our methods of spraying, &c.

First Volume.—These observations are explained in the introduction to the first volume. It is pointed out what should be considered a disease, and the conditions of plants changed by cultivation for the purpose of utility, though they cannot actually be called diseased conditions, are referred to.

This necessitates a study of the dependence of an organism on its surrounding, and answers the question of the primary cause of disease, mode of parasitism, heredity of diseases, and degeneration. The special text treats in the first instance of such unsuitable conditions of soil, as may be due to exposure or mechanical influence. In the same part the chemistry of the soil, superabundance or deficiency of water or nutritious matter, is discussed. In the second portion the author deals with atmospheric conditions, in particular injuries by frost and the evil effects due to superabundance or deficiency of warmth and light, or lightning, storm, and hail. In the conclusion of the first volume, the damages by noxious gases are described. Of great practical value will be found the advice how to treat wounds on trees, &c., the chapters on manipulating hide-bound trees, on grafting and pruning, which have been richly illustrated with drawings based upon scientific investigations.

In the second volume, Professor Lindau begins with the explanation and description of diseases caused by plant-parasites; in the second part he intends dealing with parasitic Algae, and in the last with phanerogamic parasites. In the first chapters we are glad to say bacterial diseases of plants have been treated with great care, and the great gap noticed in other handbooks of plant-diseases is herewith filled. Later on, mycelial fungi (*Eumycetes*), in the following orders of *Phycomycetes*, *Oomycetes*, *Zygomycetes*, *Ascomycetes*, *Basidiomycetes*, and *fungi imperfecti*, will be dealt with.

Dr. L. Reh is responsible for the third volume. His speciality is the investigation of the morbid conditions caused by injurious insects, and the methods of treating such attacks. Starting with the systematic arrangement of worms and noxious Crustaceae, other chapters deal with centipedes, scolopendria, spiders, mites and other insects, and finally with vertebrates. In connection with the description of the parasites of the animal kingdom, the author considers their natural enemies, both from the animal and the plant world (insect-killing fungi, &c.), and the mechanical means of combating such pests. The last section treats of the predisposing conditions of plants for attacks of parasitic insects.

Each special author has endeavoured to give scientific information, but in a simple manner, so

as to enable every reader, even one without previous knowledge of the subject, to make ready and efficient use of the material. The handbook is plentifully illustrated, printed in large type of Roman characters on a good quality of paper. It will be issued in sixteen to eighteen parts, at the price of three shillings each, and is intended to be concluded by the end of next year. H. G.

THE FERTILITY OF LAND.

A VERY interesting article appears in the second number of the new *Journal of Agricultural Science*, by Mr. A. D. Hall, M.A., the Director of the Rothamsted Experimental Station, "On the Accumulation of Fertility by Land allowed to Run Wild."

an extensive vegetation may decay with such rapidity that no reserve of fertility accumulates. In temperate climates, and with a particular distribution of the annual rainfall, occur the grassy, treeless prairies and steppes which provide the ideal conditions for the accumulation of fertility. But that fertility does increase when land is in the state of permanent grass has long been an axiom in agriculture, and the results brought forward by the author from the researches of Rothamsted show at what rate the increase takes place under prairie conditions in this country—namely, when the land is left absolutely to itself and not even grazed by stock.

In 1882 about an acre of land, which had carried Wheat for forty years in succession in the famous experimental Wheat-field at Rothamsted, was not harvested, the crop was allowed to stand and shed its seed without cultivation of any kind. In the following season a fair quantity of Wheat came up on this part of the field, but gradually got weaker as the season advanced, and the weeds increased their hold on the land. The Wheat was left to struggle on without cultivation, and by the fourth season only a few stunted plants of Wheat could be found, each carrying but one or two grains in the ear. With these the Wheat disappeared, and has never been seen again in that part of the field. This illustrates the fact that our farm-crops have become so specialised that they are unable to exist in competition with weeds and other natural vegetation, and are entirely dependent on cultivation to relieve them from that competition.

The piece of land in question has been left untouched since that time, and has covered itself with a coarse, grassy herbage interspersed with Thorn-bushes and Briars, young Oaks, and other shrubs of the district. This piece of land now represents the results of something more than twenty years of prairie conditions in England, and as samples of soil had been taken at starting, it affords an opportunity of gauging the rate at which fertility is accumulating. A very similar experiment was also made with a portion of another field which had carried Beans from 1847 to 1878, and Clover from 1883 to 1885. After the Clover the field was fenced off, and has been left untouched ever since.

Both of these fields show a marked gain of carbon and nitrogen down to the depth of 27 inches, the increase in the lower depths being due to the roots which have decayed in that stratum. The total gain of nitrogen per acre is estimated at about 2,200 lb., which is at the rate of more than 100 lb. per acre per annum. So great an accumulation of nitrogen is manifestly impossible to account for in the present state of our knowledge, and is left unexplained by the author. A point of considerable interest is that at the present time (1905) the vegetation on the Wheat-field waste contains a fair proportion of leguminous plants, while this class of plants is, and has been for many years, since the dying out of the Clover, absent from the field which had previously carried Beans. It is therefore impossible to refrain from correlating the absence of leguminous herbage on these old Bean and Clover plots with the well-known fact that land becomes "sick" of the leguminous crops in a way that never happens with other farm crops. J. J. Willis, Harpenden.

FIG. 20.—SWEET PEA HENRY ECKFORD: COLOUR SALMON-SCARLET. An excellent variety seen in general collections this year for the first time.

PLANT PORTRAITS.

VRIESEA x LEOPOLDIANA.—A cross between *V. splendens* and *V. Malzinei*. Wittmack in *Garten Flora*, t. 1539, June.

HEMANTHUS "FASCINATOR," a form of *H. Lindeni*. *Wiener Illustrierte Gartenzeitung*, June.

ROSE LILLA RAUTENSTRAUCH, H.T. Lambert, flesh-coloured. *Rosenzitung*, May.

RHODODENDRON NUTTALLI, *Revue de l'Horticulture Belge*, July.

It is well known that the fertility of "virgin" soils is due to the accumulation of the *débris* of a natural vegetation which has been in occupation of the soil for a long epoch previously. Only when the climate and rainfall are suitable to the growth of the plants and the partial preservation of their residues does a virgin soil of any richness arise. On the one hand, virgin soil may be as poverty-stricken as the most worn-out European field, because it has never carried any vegetation; on the other hand, as in the tropics, the *débris* of

THE GHENT RAILWAY STATION.—Many of our readers are familiar with the railway-station at Ghent, and will be interested to hear that a large square space in it, left unoccupied in consequence of some recent alterations, has been utilised as a garden. Australian Palms, Mexican Agaves, Brazilian Musas—in fact, plants from all quarters of the world flourish side by side, foliage-plants being mixed with Pelargoniums, Begonias, and other summer flowers. The whole is a charming oasis in a desert of platforms and locomotives, and it gives pleasure to every traveller who passes it.

THE FERNERY.

THE WHITE FLY, ALEYRODES VAPORARIORUM.

IN my cool fernery this pest is one which is constantly attempting to invade it from the beginning of May onwards, and if allowed to obtain a footing it does more than any other pest to disfigure the plants. It appears not only to suck the pieces of the fronds, but also to gnaw their epidermis, since wherever they congregate or where one has settled for a short time, a sinuous white marking appears, not unlike that produced by the operations of mining grubs. During the winter, under the quite cold conditions to which my Ferns are subjected, they disappear entirely, and since the flies do not start with a maggot form, they do not hibernate as grubs in the soil. Eggs alone enable them to reappear the following season, and these are plentifully laid upon the discoloured fronds. The result is that deciduous Ferns are quite free from attack until the fitting or perfect stage is reached, while evergreen ones are the sole source of the succeeding generations, and show signs of their presence by minute markings as described as soon as the eggs are hatched.

Early in April the hatching begins, sometimes earlier in mild seasons, and the larvæ are then visible on the frond backs only as tiny, whitish, slow-creeping insects, which appear to travel but little, feeding exclusively on the old fronds on which they originate. It is quite a month or six weeks before they arrive at full growth, when they are light-brown in colour, and then after a short period of dormancy in a chrysaloid state they turn into the white or greenish-yellow flying form, and may then be found still on the undersides of the fronds in a more or less quiescent state for some days afterwards, especially if the weather be dull and cool. A warm day, however, stimulates them to activity, and their jerky snipe-like flight begins conjointly with a general attack upon all the Ferns, and very quickly with a general distribution of eggs, which now speedily hatch, the whole place becoming pervaded with fresh generations of life unchecked. With a knowledge of their genesis in the spring, however, as indicated above, it is fairly easy to nip the invasion in the bud by means of XL-All vapour in the proportions prescribed by the makers. I prefer the liquid form to the cake after trial of the latter. This remedy should be used in April as soon as the young are perceived on the old frond backs, and if applied then it will destroy the entire generation at one operation. If left until the white flying form is seen, two vaporisings are advisable at intervals of a week or ten days, since it is fairly sure that a certain percentage of the insects will be in their temporary dormant transition stage, during which they appear to be indifferent to the effects of the fumes, and consequently survive. The second fumigation destroys these, and none is left. Under warm winter conditions I cannot speak from experience as to their hatching-time, but it is clear that that is the point to study, as there is ample subsequent time to take measures to eliminate the pest. This fly is supposed to be an exotic introduction, but if so it has certainly naturalised itself thoroughly, for it is by no means confined to glasshouses, being plentiful all over the country where Ferns and probably other plants are weakened by over-shady conditions. In my own garden the Roses are a prey to it as well as the outdoor Ferns, and it makes its appearance in the flying state out-of-doors simultaneously with its fellows under glass. I have alluded to its erratic flight, and in this it reveals an instinctive cunning, since it may be seen darting in zigzag fashion to an adjacent frond, as we imagine, but

slipping behind it, it will settle on another, and thus elude our search unless we know the trick. The best way is to note where their fresh markings appear, or where the insects seem to alight, and then to glance upwards, when despite their colour they may be discerned as dark markings, and be caught by a rapid pinch of finger and thumb, as they are a trifle sluggish in starting, and in chilly or dull weather especially fly but little. *Chas. T. Druery, V.M.H., F.L.S.*

THE GROWTH OF CONIFERS.

THE following details relating to the trees at Murthly in Perthshire are taken from the last number of the *Proceedings of the Royal Scottish Arboricultural Society*. It is interesting to compare these figures with those given in the "Conifer Conference Report," relating presumably to the same trees, in the *Journal of the Royal Horticultural Society* (1892), vol. xiv., p. 533.

Note.—The measurements are taken at 5 feet from the ground.

In the Forestry Section at the recent Royal Agricultural Society's Show at Park Royal, photographs of a few of the largest Conifers at Linton Park, Kent, were exhibited. The measurements taken in 1903 were as follows:—

NAME OF TREE.	Years of age.	Height.	
		ft.	ft. ins.
<i>Abies concolor</i>	44	87	11 7
" <i>nobilis</i>	59	83	7 8
<i>Tsuga Mertensiana</i>	41	72	5 8
<i>Pinus austriaca</i>	64	83	9 0
<i>Sequoia sempervirens</i>	61	68	12 0
<i>Sequoia gigantea (Wellingtonia)</i>	44	81	12 1
<i>Pinus excelsa</i>	61	64	9 0
<i>Abies cephalonica</i>	59	73	11 0

Details concerning these trees were also given in the "Conifer Conference Report," p. 491.

PUBLICATIONS RECEIVED.—*Bulletin of the Department of Agriculture, Kingston, Jamaica, June.* Contents: Report on Diploma Examination, Bud-rot of the Coconut Palm. "The disease is the result of a bacterial rot of the terminal bud and its wrappings, including the flower-buds. Diseased trees should be felled, and the terminal bud burned or properly disinfected with sulphate of copper. Only the most energetic action is likely to avail."—*Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information.* Appendix III., 1905. Contents: New Garden Plants of the Year 1904, a valuable list for horticulturists and botanists.

The Week's Work.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

The Wild Garden.—The following are a few of the stronger-growing plants in flower at the present time:—*Crambe cordifolia*, a Cruciferous plant, developing large panicles of white flowers; *Ligularia macrophylla*, with oval glaucous leaves and dense heads of yellow flowers; *Phlomis fruticosa*, a hardy shrub, with greyish-coloured foliage and yellow flowers, a useful subject for furnishing steep banks; *Carduus heterophyllus*, the flowers of this plant present a bright patch of purple colour, which, in company with the white-coloured variety of the Melancholy Thistle, forms a good contrast in colour; *Epilobium angustifolium*, the well-known Willow-herb.

The Rock Garden.—*Romneya Coulteri* should be furnished with liberal supplies of water to encourage strong growth. *Edraianthus dalmaticus* and *E. serpyllifolius* are both comparatively easy of culture. If the roots of these plants have been washed bare of the soil by heavy rains give them a top-dressing of sandy leaf-mould. *Bellis rotundifolia* *corulescens* should be planted in a sheltered corner of the rockery. *Lathyrus rotundifolius*, Wood's variety, develops a salmon-scarlet-coloured flower of very pleasing appearance. *Colutea bullata* is a "pigmy" amongst the Bladder Sennas, its crowded habit of growth is a noticeable character of the species. Keep a sharp look-out for snails.

Shrubberies.—See that freshly transplanted trees are well supplied with water, especially during a period of drought. *Kalmia latifolia* is a very choice shrub. It should receive the same treatment as is given to *Rhododendrons*, and forms a good subject for planting in the front row of the border, as it is rather slow in growing. It is a favourite plant for furnishing cut flowers, which last for a long time when placed in water. *K. angustifolia* is smaller than *K. latifolia*. *Zenobia speciosa* forms a good companion plant to the above. This plant requires shelter, and thrives well in a compost of loam and sandy peat. *Diervilias* are conspicuous shrubs when in flower, and succeed in any ordinary garden soil. The varieties *Van Iloutte* and *Eva Rathke* are of the best forms.

Dahlias.—Place strong stakes to support these plants, and frequently apply waterings of weak liquid-manure. If earwigs are destroying the growing points, trap them in small flower-pots half-filled with hay, and inverted on the top of the stakes. Rarer varieties can be propagated from small cuttings placed in a shaded propagating case.

Tulips.—Bulbs planted especially for supplying cut flowers should be lifted every two or three years after the foliage has become yellow and limp. Sort the bulbs, and store them till planting-time arrives. Late-flowering self-coloured varieties and the Parrot Tulips are excellent subjects for indoor decoration.

Anemone coronaria should also be lifted and divided when the foliage has matured. This plant can also be propagated from seed. Beds of the various kinds of *Narcissus* that have become too crowded should have the bulbs lifted and transplanted when the foliage has died down.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Lalia Jongheana often fails to flower, the cause being in most instances that the plants are grown in too warm an atmosphere and shaded. The best results are obtained by growing the plants in baskets or perforated pans, suspended near the roof-glass of a cool intermediate-house, and kept there throughout the year. Should any of the plants need fresh rooting material, it may be afforded now whilst they are making new growth and roots. They must never be given large or frequent supplies of water, though naturally most will be needed when root-action is greatest. During the long resting period the plants will only require water after long intervals of time,

but it should be supplied before much shrivelling is evident in the pseudo-bulbs.

Laelia pumila and its variety *praestans* differ from the above in that these require more dense shading and ample supplies of water, though as regards temperature, &c., their requirements are nearly the same. These may be grown in small pans with perforations in the sides, good drainage, and a small portion of equal parts of peat and sphagnum-moss to root in. New growths are now starting, and repotting or renovation of the surface materials should be proceeded with ere long. The variety *L. p. Dayana* requires a cool, moist atmosphere at this season; it should be well shaded, and never be allowed to suffer a long period of drought at the base. Cultivate the plants in pans or baskets, affording plenty of drainage material, and a small portion of peat and sphagnum-moss, which may be renewed as soon as new growths appear.

Laelia cinnabarina, which has proved such a valuable agent for hybridisation purposes, is a somewhat difficult species to keep in good condition. A fair measure of success may be obtained by growing it at the cool end of a *Cattleya*-house in well-drained pots, and treating it somewhat similarly to the *Cattleyas*, though, if anything, it must be kept dry for a longer period, and only be given a very moderate supply of water when growing. During healthy root-action liberal applications may be administered if the plants are in peat and sphagnum-moss, but should leaves be introduced a more restricted supply must be given.

Laelia harpophylla should be grown under cooler conditions than *L. cinnabarina*, a moderately light position in the cool intermediate-house suiting it best. Having more slender pseudo-bulbs, the plants must not be subjected to protracted periods of drought, though when in a dormant state infrequent waterings will be all that is needed. This species succeeds when grown in a leaf mixture, which, however, should be kept very porous by adding some small crocks.

Laelia monophylla also thrives when leaves are added to the rooting medium. It may be planted in a pan half filled with drainage material, then adding a layer of the mixture and a surfacing of chopped sphagnum-moss. Suspend the plants at the warm end of an *Odontoglossum*-house, and whilst growing and developing their tiny floral scapes, keep the materials in a moist condition, but throughout the rather long resting period only apply water when shrivelling is anticipated.

Laelia flava, *L. longipes*, and allied kinds grow best in shallow baskets with very little material about their roots, and their cultural requirements are usually obtainable in a cool position in a *Cattleya* house. Much water is only required when the plants are rooting freely. *L. rubescens*, also known as *peduncularis*, should be grown in a basket placed near to the glass at the warmer and lighter part of this house, and be kept well on the dry side, excepting in the most active season.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Cabbage Seeds.—The early spring Cabbage is a vegetable of considerable importance, and the best variety that I know for this purpose is Ellam's Early, which has proved more satisfactory than all others grown side by side here. Sow the seeds on rather poor, well-worked, and clean ground. Throw plenty of lime into the soil during its preparation, and apply water if the soil is in a dry condition. Give a good dusting with soot previous to sowing the seeds. Sow thinly in order that the plants may have every chance from the commencement to grow sturdily and make many roots. The third week in the present month will be sufficiently early for the first sowing to be made, and a fortnight later the main crop may be sown; also seeds of the Red or pickling Cabbage, which in some establishments is much valued for cooking purposes. By about the third week in September these plants will be sufficiently advanced for planting out. Such varieties as Ellam's Early need not be given more than 15 inches between the rows, and a foot from plant to plant in the row. Larger-growing varieties will need a distance of 2 feet each way.

Peas.—Late crops are of considerable importance. When late plants are well above the ground, thin them out freely if they are too thickly placed. Then apply a mulch of stable-yard manure, and if the weather is dry afford plenty of water to the plants. When sowing late crops of Peas, bear in mind that they may have to withstand rough weather and high autumn winds.

Globe Artichokes.—Heads of fine quality can only be obtained from a good variety, and after liberal cultivation, otherwise this vegetable may be considered little better than an overgrown weed. During the summer months the plants require much moisture at the roots in the form of liquid-manure, and also liberal mulches of farmyard manure. If they are given these conditions, and the heads are kept regularly cut before the stem becomes firm, the fleshy scales, for which they are cultivated, will be in the best possible condition, and may be kept so for at least a week after being cut, provided the end of the stem is placed in water in a cool place.

Early Potatos.—When the ground is required for another crop the Potatos may be lifted and stored, but until the skins are well set the work will have to be done with the greatest care, and the tubers removed to a dark, cool site. Exposure to the light at this season would soon depreciate the appearance of the tubers for table use.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Layering of Strawberry Plants.—Immediate attention should be given to this work. Those cultivators will obtain the strongest layers who possess young plants put out late last summer for this purpose, and which have had all their flower-trusses removed. Such plants will produce very strong runners, equally valuable for layering for forcing, or for raising plants to be grown in beds. The variety *St. Antoine de Padoue*, if required for fruiting in pots during the coming autumn and winter months, should be layered at once into the pots in which they will fruit. Afford them close attention in regard to the application of water to the roots and syringing of the plants. Expose them to full sunshine. For forming permanent beds or for planting-out on the short cropping system, the layers should be placed in 3 or 4-inch pots, filling the same up to within 1 inch of the rim with a good rich compost, in which the plants will root very freely, placing a stone on each layer to secure it in position, and to conserve moisture about the plant. Only the strongest layer should be selected and the others be pinched off. After a month has elapsed the layers will be sufficiently rooted to be severed from the parent plant. Keep the pots moist during dry weather by plunging them to half their depth in the soil. Upon removing the rooted layers place them in a shady position for a few days. In some districts a few plants amongst some varieties become unfruitful, and care should be taken not to propagate from these. The Royal Hautbois may be grown on a partially shaded border or under the partial shade of trees. To secure fruitfulness, runners of this class must be obtained from a plantation having male and female plants.

Loganberries, Blackberries, &c.—As the new growths increase in length they should be kept free from the fruiting canes by securing them to separate poles. When the fruit has been gathered the plants should be treated as Raspberry-canecan. In districts where birds are very numerous, all ripening fruits will need to be protected with fish netting.

The Fig.—Attend to the growths of these, and secure for every shoot ample space for its development. Retain short-jointed shoots in preference to long and sappy ones. Trees carrying heavy crops and growing on porous soils should be afforded liquid-manure frequently, as advised in previous calendars.

The Codlin Moth.—This pest may be reduced by timely attention to the removal of all Apples which are infested with maggot borings. These should be carefully collected with all fallen fruits, and if not given to the pigs, should be destroyed by burning.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Amasonia punicea.—Propagation of this useful decorative plant by cuttings may still be done if it is desirable to increase the stock. Loam, peat, and silver-sand in equal parts should be the compost employed from the time the cutting is inserted until the plant blooms. Like most of the tender stove flowering plants, Amasonias are liable to attacks of mites and thrips, and precautions should be taken to guard against these pests by dipping the plants periodically in a solution of Quassia-extract. Pots containing the cuttings should be plunged to the rims in Cocoa-nut fibre upon considerable bottom-heat. Great care will be necessary to successfully cultivate the plants. Excessive supplies of water would prove fatal to them. During the period of growth let the plants be placed upon a shelf near to the glass in a warm and moist atmosphere, shading them from hot sunshine.

Thyrsacanthus rutilans may be easily propagated, and it is an effective plant for grouping in batches, &c. Cuttings inserted now and treated precisely as for Amasonias will furnish a good display of bloom during the winter months.

Jasminum Sambac, fl. pl.—The fragrance of this plant when in bloom is alone sufficient to render it indispensable, but it is also of easy culture. One plant will produce a number of growths suitable for making into cuttings. They should be detached with a good "heel" and placed in pans of silver-sand, pegging them down with a piece of wire or stick to keep them from shifting. Frequent waterings should be afforded them, and when the cuttings are nicely rooted they should be potted carefully into small pots and placed in a propagating frame for a few days. They will grow strongly, and when about 6 inches in length pinch the points out to ensure a bushy habit. The plants should be grown and flowered in an intermediate temperature, and where they will receive shade from the sun.

Hydrangeas.—Cuttings should be inserted singly in small pots for flowering in early spring.

Mignonette.—Make a sowing in pots. Use a compost of sifted lime-rubble, loam, and leaf-soil, and make this very firm in the pots. A few slates placed over the pots will shade the seeds from the sun, and also keep them cool, but must be moved directly there are signs of germination.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Strawberries.—An endeavour should be made to have all these plants in the pots in which they will bear fruit by the end of the present month. Use clean pots and provide good drainage, applying a dusting of soot over the crocks to keep out earth-worms. Good fibrous loam, manure from an old Mushroom-bed, with a sprinkling of bone-meal and of wood-ashes or lime-rubble, varying in quantity according to the nature of the loam used, will form a good compost. Pot very firmly and do not disturb the roots during the operation more than is actually necessary. As soon as the plants have begun to make fresh growth, place them on a good ash bottom on an exposed site where the sun's rays will reach them. Bear in mind that Strawberry plants should never be allowed to want for water at the roots. Pinch out the runners as they appear, and keep the soil in the pots free from weeds.

Peach and Nectarine-trees growing in pots in an orchard-house require very careful treatment. During the latter stages of growth the fruits swell rapidly, and rich stimulants should be given until the fruits approach ripeness. Over-cropping of weakly-growing trees should be particularly guarded against. Continue to pinch out the laterals until the end of the present month, and prevent any overcrowding of the shoots by removing such as will not be required for bearing fruits next year or for the proper furnishing of the trees.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JULY 18	Royal Horticultural Society's Committees Meet, and National Carnation and Picotee Society's Show. National Rose Society's Show at Gloucester.
WEDNESDAY, JULY 19	Northumberland and District Flower Show at Newcastle (3 days). Wimbledon and District Flower Show.
THURSDAY, JULY 20	Horticultural Club (annual outing. Visit to Wisley).

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63'4".

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, July 12 (6 P.M.): Max. 79°; Min. 64°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 13 (10 A.M.): Bar., 30'3; Temp., 72°. Weather—Bright sunshine.

PROVINCES.—Wednesday, July 12 (6 P.M.): Max. 74°, Guildford; Min. 57°, N.E. Scotland.

The Chelsea Show of the Royal Horticultural Society.

FAVOURED with brilliant weather, and in an ideal situation, the Show of the Royal Horticultural Society in the grounds of Chelsea Hospital was in so far a great success. The site was all that could be desired, with fine trees, shady avenues, and ample space for tents and visitors. Close by are the Ranelagh Gardens, under the charge of an old Chiswick man, and themselves good examples of the landscape gardener's art, with their picturesque undulations, the well-kept sward, and the trees, many of which are of great interest and beauty. The gardens, tended by the Chelsea pensioners themselves, often decorated with the flag they served so well, and filled with Carnations and other flowers, together with succulent Lettuces, are pathetic, and call for sympathy and gratitude to the veterans who are passing the evening of their lives in this pleasant retreat. Very pleasant also was it to hear Sir GEORGE WHITE'S crisp speech at the luncheon given by the Council to the Committees. Sir GEORGE WHITE—he of Lady-smith—is now Governor of Chelsea Hospital, and it was largely to him that the Society was able to hold its show in so admirable a site. An acknowledgment was therefore due to him, and his impromptu speech in reply, though brief, was quite one of the best we ever heard on a similar occasion, and served, had such been necessary, to deepen the gratitude and respect felt for the distinguished soldier.

As to the Show itself it was large, and the space available was large also, so that the crowding experienced at the Temple was not felt here. As an exhibition it was exceedingly pretty, and the quality of the exhibits good throughout, though, so far as we saw, there was no very striking novelty or plant of special interest. But the site and the other circumstances we have mentioned rendered the Show one of the most pleasant

and satisfactory within our recollection. Occasion was taken, as we have already mentioned, by the President and Council to call the Committees together at the luncheon and to express, through the President, an acknowledgment of the services so disinterestedly rendered by the members. It is not often that the Council and the Committees can meet together, but such meetings are most advantageous and agreeable, tending as they do to facilitate the work of the Society, and to promote goodwill and earnest co-operation all round. We must not forget the heavy labour thrown on the Secretary, the Superintendent, and the members of the staff on these occasions, nor can we fail to acknowledge their courtesy and assistance to the Press. For the details of the Show we must refer our readers to another column.

Some of the visitors to the Royal Horticultural Society's show took the opportunity to look in at the old Physic Gardens, which is not more than five minutes' walk from the site where the show took place. The alterations which have been made in the Physic Gardens during the short time that has elapsed since its reorganisation are very marked indeed. We have never seen the Garden in such generally good condition as it is now. Mr. W.M. HALES has not only shown that he could remake the walks, restore the verges to neatness and make and keep the Garden tidy, but that he is also a first-rate cultivator of plants.

There is now a very nice selection of species in the houses, a selection that is especially useful to students, and the species are happily represented by well-grown examples. There is no reason why a collection of botanical plants should appear "weedy," if the same pains be taken to grow them well as are bestowed on the culture of decorative plants in any good garden. In the beds out-of-doors the same care is evident, and the examples of this and that "Order" are very much better than they might be expected to be in such an unfavourable situation. We will only mention one instance of this, though there are many that could be enumerated. *Romneya Coulteri* has grown to a bush of about five feet high, and as much through. At the present time this fine specimen is furnished freely with flower-buds, that in the course of a few days will afford quite a delightful show.

BRUSSELS BOTANIC GARDEN.—Our Supplementary Illustration shows a view in the Victoria-house at the Brussels Botanic Garden. It tells its own tale, but it also gives us an opportunity of alluding to the changes that have been made in the arrangement and disposition of the plants. In times not far remote, a botanic garden, especially a continental one, was too often a miserable spectacle. The cultivation of the plants was bad, the houses ill-constructed, the means at the disposal of the authorities wretchedly inadequate, and the arrangement of the species, such as it was, strictly according to the natural orders to which the plants belonged. Nowadays, a different plan is carried out. Classification is not neglected, but in addition physiology, variations and adaptations to circumstances are illustrated by the living plants. At Brussels, and to some extent at Zurich and at Basle, it would almost seem as if the directors had taken DARWIN'S *Animals and Plants under Domestication*, DE VRIES' lectures or similar works, and had set to work to illustrate

them (so far as the plants are concerned), so that the books in question form to a certain extent a detailed catalogue of the contents of the garden. Some pamphlets explanatory of the arrangements made at Brussels may, from their completeness, be taken as an index of the various adaptations to circumstances manifested by plants, of their manifold variations, their response to stimuli, their hereditary characteristics, and so forth. In the Cactus-house at Brussels the plants are even so arranged that they show the presumed relationship and derivation of each group. A genealogical tree is thus constructed, the study of which cannot fail to impart to the observer new ideas as to the meaning of the conformation of the several plants, and to enable the student to appreciate the significance of much which before was meaningless. A botanic garden so arranged is thus made the means of conveying much more varied information than was formerly the case.

FLOWERS IN SEASON.—From Messrs. ROBERT VEITCH & SON, of Exeter, we have received a collection of interesting and attractive plants, such as *Coriaria terminalis* with long spikes of yellow berries (see *Gardeners' Chronicle*, October 24, 1903, p. 282), *Lonicera Hildebrandtiana*, the remarkable Honeysuckle with very long yellow flowers (see *Gardeners' Chronicle*, September 17, 1898, p. 219).

Spiraea Aruncus Kneiffii.—A variety with the elegant spray-like inflorescence of the common form, with remarkably deeply lacinate foliage.

Ceanothus "Indigo".—A form whose name is indicative of its colouration.

Dianthus Emile Paré is one of the mule pinks, of free-flowering habit, and small flesh-coloured double flowers.

Genista ænensis.—A leafless or nearly leafless species, with numerous slender, cylindrical, green branches (virgate), bearing dense masses of yellow, pea-shaped flowers.

—Mr. R. LINDSAY, of Murrayfield, Midlothian, sends us a specimen of a shrubby *Senecio*, *S. Buchananii*, from New Zealand. It has ovate, leathery, rugose leaves covered with rust-coloured down on the under surface. The flower-heads are numerous in terminal panicles, without any ray-florets. Mr. LINDSAY tells us it forms a compact bush about 2 feet in height.

"BOTANICAL MAGAZINE."—In the June number coloured figures and descriptions are given of the following plants:—

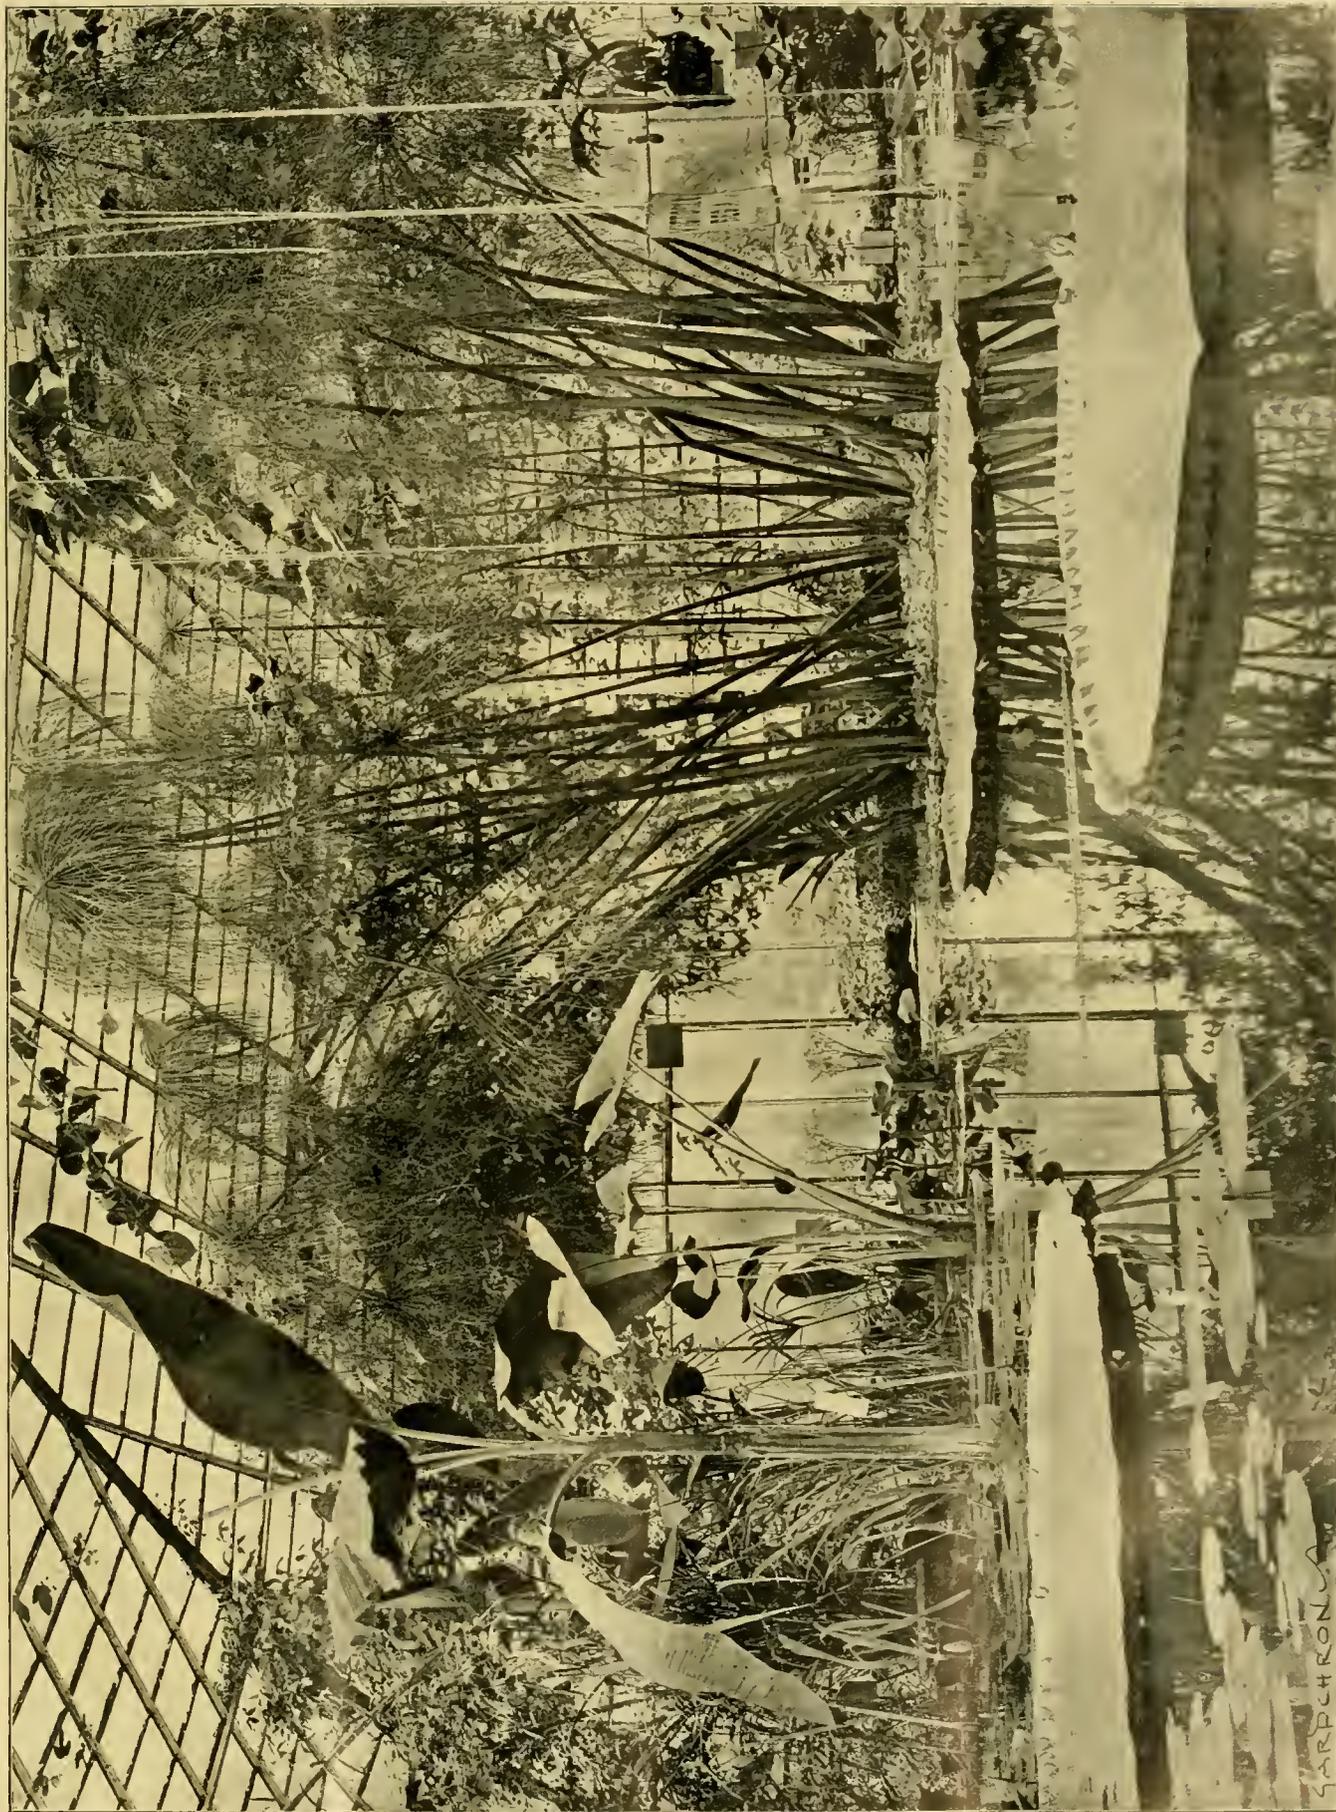

Cucullia tuberosa, Nuttall, t. 8022.—An extraordinary plant with great, broad, many-ribbed, succulent leaves like those of a *Funkia*, but with a loosely-branched corymbose cyme bearing what look like the fruits of some Umbellifer, but which examination shows to be Composite flower-heads. It is a native of North-east America, but the specimen figured was communicated by Mr. W. E. Gumbleton.

Pernettya mucronata, Gaudichaud, t. 8023.—A plate showing varieties with differently coloured berries. The rarity of colour-variation in fruits, at least so far as decorative purposes are concerned, is commented on.

Coleus shirensis, Gürke, t. 8024.—A species from British Central Africa closely allied to *C. thyrsoideus*, but differing in the foliage. It flowered at Kew during the winter and early spring.

Colchicum Steveni, Kunth, t. 8025.—A Levantine species which produces its small lilac-coloured flowers simultaneously with the leaves. The flowers are destitute of the checkered markings so conspicuous in other species.

Listrostachys Monteirae, Rehb. f., t. 8026.—An Orchid from West Tropical Africa with the habit of an *Angræcum*, bearing long, pendulous racemes of buff-coloured, long-tailed flowers from the axils of broad, oblong, retuse leaves. Kew.

VIEW IN THE VICTORIA HOUSE IN THE STATE BOTANICAL GARDENS, BRUSSELS.

THE VICTORIA NECTARINE.—This is a variety whose fruits are of rich flavour, of rather more than moderate size, and which are generally more or less green in appearance. It is essentially a Nectarine that requires to be grown under good conditions in a glass-house. We have recently received half-a-dozen fruits from Mr. W. HONESS, Cobham Park Gardens, Cobham, that were so highly coloured that they might easily have been mistaken for another variety. It is only in favourable southern districts that Victoria can be grown so well, but when this has been done the variety is superb.

DAMAGE BY THUNDERSTORM.—Much damage was caused to garden crops in Middlesex, Surrey, and Essex on Sunday, July 9, when a violent thunderstorm, accompanied by a deluge of rain, visited London and the neighbourhood. Our correspondent, Mr. MARKHAM, Wrotham Park Gardens, Herts, states that the rain-gauge there measured 3 inches of rain during the day, and that the fruit and vegetable crops were almost decimated by the large hailstones that fell. Mr. STEPHEN CASTLE writes, stating that in Mr. J. SWEET'S market nursery at Whetstone the damage to glass in the vineries and plant-houses was very great, but it is practically covered by insurance. Far greater damage was, however, done to the 100,000 plants in the standing beds outside. Ericas were badly cut, and damage is feared also from the fact that the pots were flooded. Marguerites were entirely ruined. Hydrangeas were riddled, and rendered almost leafless.

WAKE UP, OXFORD!—According to a statement published in the current number of *Nature*, no less than a sum of £564,000 as capital and an annual income of £93,000 is required in order to bring the University up to its proper level as a means of advancing learning in various branches, not omitting the classical and modern languages, mathematics and theology, but including also many subjects now imperfectly provided for. We have slipped so far behind American and German, and to some extent even Japanese educational establishments and methods that the sums above mentioned, though apparently large, are doubtless no more than adequate. In the same journal we read that Mr. ROCKEFELLER has presented to the General Educational Board, for the extension of higher education in the United States, the sum of £2,000,000, as well as a gift of £200,000 to Yale University. After that the half-million asked for Oxford seems paltry.

WATER-CARNIVAL IN GHENT.—On the occasion of the seventy-fifth Anniversary of Belgian Independence, the Communal Administration of Ghent organised a most successful water-party. This took the form of a procession of boats, some fifty-three in all, prettily and artistically decorated with flowers and other ornamental accessories. Knowing well the natural advantages of the town for such a water carnival and the excellent taste of our Belgian friends, we can well understand that the scene was very beautiful. Enormous quantities of flowers were employed; we read, for instance, of more than one thousand blue-flowered Hydrangeas being seen in one arrangement, charmingly blended with pink varieties of the same plant. The whole affair reflected much credit on both organisers and participators.

OVER-SEA SUPPLIES: JUNE.—The Trade and Navigation Returns for the past month continue to bear an inspiring aspect, both imports and exports exhibiting an increase as compared with June, 1904—the latter being very marked. The imports reached £43,557,407, as compared with £42,196,784 for the same period last year. The exports are recorded at £25,985,397, as compared with £24,069,770 for June last—an increase of

£1,915,627. Appended is our usual list of fruit and vegetable imports:—

IMPORTS—JUNE.	1904.	1905.	Difference.
Fruits, raw—	£	£	£
Apples	113,679	53,177	-60,502
Apricots and Peaches	4,619	6,911	+2,302
Cherries	170,623	146,723	-23,900
Gooseberries	13,402	7,183	-6,219
Pears	974	98	-876
Plums	1,353	219	-1,134
Strawberries	39,360	28,326	-11,034
Vegetables, raw—			
Onionsbush.	46,989	50,251	+4,562
Potatoscwt.	681,083	644,232	-36,851
Tomatos	135,927	124,869	-9,058
Gross total, including varieties of fruits and vegetables not enumerated in this Table	1,698,334	1,484,781	-213,553

Compared with the above totals, those for June, 1885, only twenty years since, are of interest to all: Apples, 389 bushels; miscellaneous (the only other record), 191,009 bushels; total value, £170,867. The reader is doubtless aware that there has long existed in Rotterdam an Onion and Potato Exchange, doing business during part of the year. Fruit and vegetables generally are now to be added to the business, and the Exchange will be open all the year round. Imports of cut flowers for the past month were valued at £13,115, as against £12,475 for June, 1904—a gain of £640.

MEDAL FOR STRAWBERRIES.—We omitted to state on p. 34 that Messrs. GEO. BUNYARD & Co., Maidstone, were awarded a Silver Knightian Medal for the collection of sixteen varieties of Strawberries exhibited at the Royal Horticultural show on the 4th inst.

"THE BOOK OF THE SCENTED GARDEN."—By F. W. BURBIDGE. (JOHN LANE, The Bodley Head, London and New York.) This book is an expansion of a paper on "Fragrant Leaves v. Sweet-scented Flowers," read before the Royal Horticultural Society in 1898. It makes pleasant reading, for it includes legends and poetical quotations as well as more serious discourse concerning the sense of smell and its use or neglect. The essential oils and their uses are mentioned, and so are chemical perfumes. There is no attempt to compile an absolutely complete reference work upon vegetable perfumes. At the same time, most of those best known are mentioned. A chapter on the scent of fruits would have proved interesting. Mr. BURBIDGE claims that floral odours are evanescent and leaf-odours permanent, or, as he expresses it: "Flower perfumes are positive, being mostly given off whether we like it or not; and some people are so extremely sensitive to perfumes that those of Hyacinths, Narcissus, some Lilies (especially *L. auratum*), and even Roses, prove disagreeable, and at times actually injurious. To those who suffer from strong floral perfumes I can strongly recommend the more negative qualities of fragrant leaves." A list of books relating to the subject, from Exodus to BULWER LYTTON and Mrs. EWING, is given, as well as an alphabetical list of plants yielding perfumes, and a general index. We should have liked to see some further allusion to the purpose and significance of these varied perfumes. Some mention might also have been made of the atrocious odours of some Arums, *Stapelias*, *Phallus impudicus*, &c., because, however objectionable to us, they are evidently appreciated by other members of the cosmos, and have their place in the vast system of the universe. Altogether this is a welcome addition to the Handbooks of Practical Gardening—a series to which we have frequently before had occasion to refer favourably.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE NATIONAL SWEET PEA SOCIETY.—My primary object in writing this letter is to appeal to schedule-framers and committees of societies to request that in framing their schedules and regulations to exhibitors they will adopt clear and unmistakable terms, and will refrain from imposing conditions that exhibitors cannot comply with accurately unless they possess the precision of an automatic machine. In Class 1 for nineteen bunches of Sweet Peas, in which was offered the Sutton Challenge Cup, a Gold Medal and £3 in cash as the 1st prize, some half-dozen (I believe the correct number was eight) of the collections were disqualified owing to the inclusion of one or two flowers too many throughout the whole collection of nineteen varieties. Amongst these unfortunate exhibitors were several members who have supported the Society from its start, and have become annual exhibitors, and the collections were brought and staged, after being grown specially for the class, from a distance of over 300, 200, and 100 miles respectively. Is it fair to these exhibitors, who did their best to comply with the conditions of the competition, that it should be possible for them to be disqualified simply because in a collection of Sweet Peas, in which they were required to set up 350 flower-stems, they happened to have 381 or 379? Strangely enough the judges passed over those exhibits which contained fewer than the required number, and awarded prizes to two of these collections, some of the vases containing only fifteen and eighteen flowers. Now the schedule reads thus:—

"Class I. Special Audit Class.—Nineteen bunches of Sweet Peas." (The varieties to be shown are specified.) At the top of this page of the schedule is a head-note—"In Classes 1 to 35 inclusive twenty sprays shall form a bunch, more than this will disqualify."

Now I maintain that fifteen or eighteen sprays do not constitute a bunch according to the terms of the schedule, therefore those exhibits which contained fewer than twenty sprays in a vase were equally "not according to schedule." I do not pretend to say that the judges were wrong in disqualifying those exhibits in which they found in one or two vases twenty-one flowers; but I do complain of the stipulation that makes such an error difficult to avoid. I will also show that the judges in their endeavours to follow the stipulations of the schedule on this one point, passed over far graver grounds for disqualification which were found to exist in two of the collections to which they awarded prizes. As there were but three of the collections in this class which the judges had not disqualified, several of the unfortunate exhibitors asked to be allowed to scrutinise these more fortunate exhibits. Permission to do this was granted by the Secretary and Chairman of the Committee, and in the presence of a member of the Committee and an outsider appointed by the Secretary, a thorough investigation of these exhibits was made, with the result that in the collection which had been awarded the 1st prize was found a vase containing twenty-one flowers; in that which was awarded the 2nd prize was a vase containing two varieties, viz., *Lovely* and *Jeanie Gordon*; while the vase which was supposed to represent *Jeanie Gordon* contained a variety that was not allowed in the competition at all. The remaining collection (awarded the 3rd prize), which averaged sixteen or seventeen flowers in a vase, also included a vase containing two varieties. These facts were proved conclusively, and admitted both by the Secretary and the Chairman of Committee. In my opinion, after this had been proved, one of two alternatives should have been adopted. Either the whole of the exhibits should have been disqualified and the competition have been rendered void, or the collections should have been judged on their merits by independent judges. For my own part I can easily understand how such a mistake might be made (twenty-one flowers were found in two of my vases). I have always made a practice when staging flowers at the National Sweet Pea Society's show to count out twenty of the best flowers

from a variety, and then proceed to arrange a vase. Placing them in one by one, I possibly come across a flower that is not quite up to colour, or which has some other defect. It is put aside and another flower is substituted to make up the exact number. Perhaps one's attention is diverted for the moment by some inquirer, or by some unavoidable jostling of passers-by in the busy room, and two flowers have been added instead of one, or the offending flower has not been abstracted. Such a mistake is almost excusable when one has to put up say some sixty or seventy bunches in a given time, and the exhibitor wishes to stage them to the best advantage. If a slight margin were allowed a poor flower might be discarded without having to include another. It is very disappointing when exhibitors have spent some hours in staging their flowers to the best of their ability to see them so grievously disarranged as they were at this show in order to ascertain whether there was one flower [spray] too many in a vase. I am convinced that had the whole of the classes throughout the show been scrutinised in the same way the majority of the exhibits would have been found to contain similar mistakes. In class 2, for nineteen varieties also, the same judges acted, and two of these collections were disqualified for the same reason, but that which was awarded the 1st prize held a vase containing eleven flowers only. Should not that have been disqualified when "twenty flowers [sprays] shall form a bunch"? *F. J. Clark, Wistow Gardens, Leicester.*

— It is doubtful if there was ever such a scene in an exhibition-room as that which occurred in the Hall in Vincent Square on the occasion of this annual exhibition. Those who were not present, but have since read the reports, will know that ten of the twelve competitors in Class 1, for nineteen bunches, were disqualified, nine of them for having more sprays than the stipulated number (twenty) in a bunch. In addition to the six cash prizes in this class, the Sutton Silver Challenge Cup and a Gold Medal were offered to the winner, which handsome prizes render the disappointment all the greater to the exhibitor who had the best exhibit, but who through an inadvertence was ruled out of competition. As one of the judges who has enjoyed the honour of acting in that capacity in the two leading classes since the inception of the Society, I must say that it was the most disagreeable task that has ever fallen to my lot. If any of the exhibitors felt more miserable than I did I pity them! When I and my colleagues (Mr. C. Foster, Reading, and Mr. Burpee, New York) received our instructions as to the classes, we were entrusted with, we were told to be very particular as to the number of "sprays" contained in each bunch. In closely scanning the first exhibit we quickly found more than the orthodox number. I reported the matter to the Secretary, who was emphatic in his adherence to the rule—or special clause. In a short time we found many had committed the same error. I once more consulted him, pointing out what must eventually happen, that the whole class would be spoilt and broken up, giving much annoyance and possibly damaging the otherwise splendid display. Like a true soldier, Mr. H. Wright said, "You must carry out the regulation at any cost." We then made what I call a wholesale disqualification. The exhibitors as a body took the disappointment very well, and I think were satisfied with the explanation we gave them afterwards. Now the next point to consider is, what is likely to be the result of such wholesale disqualification, and what is the remedy? In the first place nothing but harm must follow to the Society. Although exhibitors know they were to blame, they will be chary again of going to such trouble and cost, to find all their labour lost by the inadvertence of including just one more spray than the regulation number. Now, in my opinion, the remedy is a simple one. Stipulate for so many bunches to be staged in the Society's vases which are of a uniform size and cannot hold more than a reasonable number with credit, allowing exhibitors to place whatever number they choose, in the same way that garden Roses are now exhibited. The judges would then have a more pleasant task, as they

would then consider quality of bloom, and would know how to deal with over-crowding. As long as the vases were of a uniform size, all competitors would be placed on an equality. The adjudication would then simply hinge upon correct nomenclature, quality of bloom, and taste in arrangement. If the Executive Committee think well to adopt a suggestion of this character, I believe they would act wisely in the interest of exhibitors and the Society. *E. Molyneux.*

"CROCUS ROTULORUM."—A writer in a Dunstable newspaper comments on this rare plant. The name occurs on a tablet a hundred years old in Millbrook church, Beds, erected to the memory of one Thomas Allen, a groom, by John, Earl of Upper Ossory, Amphill. The Earl himself caused the memorial to be erected, and he gives his own title as "Lord Lieutenant and Crocus Rotulorum." The manner of the groom's death is also mentioned, as well as the very great age of a horse and its burial in Millbrook churchyard, for the inscription states that the groom died "in consequence of a blow from a horse" (whether from the mouth or not is not stated) "his Lord had just dismounted him, aged 81 and is buried in this churchyard, 1805." *Custos Rm.*

LARGE STRAWBERRIES.—This season I have grown two continental varieties of Strawberry, which I imported from France. They are Gloire du Maris and Avant-Garde. The first, to my thinking, is by far the finest both in colour and size that I have ever seen. The bed where they are planted is small, yet nevertheless from a morning's gathering one weighed over 2 ounces, two turned the scale at 2 ounces, and several were 1½ ounce, and of a somewhat conical shape, while the general growth was large. The colour is a bright orange-vermilion, even, and extremely beautiful. When fully ripe the flavour is delicate and sweet. The seeds are a buff-yellow, and slightly imbedded. The inflorescence is large and plentiful, and the plant growth is healthy and strong. It is early and may be said to be prolific. It is the best fruit of the kind that I have hitherto had. Avant-Garde is small in berry; its flowers are pink, which is a new colour. It is not worth growing, the fruit being anything but pleasant to the palate. I still find the piquant Sir Charles Napier not only pleasing to the eye, but with crushed white cane sugar and cream it is delicious for the dessert. Waterloo is as usual excellent, but not very prolific. *Harrison Weir, Poplar Hall, Appledore, Kent, July 9.*

CALODENDRON CAPENSE.—It may interest readers of the *Gardeners' Chronicle* to know that my specimen in Italy of this beautiful tree has been covered for weeks with a profusion of beautiful flowers, resembling those of the Horse-Chestnut. It was planted at La Mortola about thirty-five years since, and has attained a height of 30 feet. *T. Hanbury.* [This species was figured in our issue for May 13, 1905, p. 292, and Supplementary Illustration. Ed.]

REFRESHMENTS AT THE ROSE SHOW.—The "tea under the shade of the trees" at the late Rose Show at the Regent's Park was for the few only, both accommodation and attendance being quite inadequate for the needs of the visitors. Those who ventured to wait upon themselves and carry away chairs and ices to some little distance from the refreshment-room were unfortunate in finding the ices unacceptably salt and otherwise undesirable. The scarcity of waitresses, of tables and of chairs, and of tempting refreshments, was the subject of much comment. [Many similar complaints have reached us with reference to the refreshments at the Temple, and even at Chelsea, and as these complaints are repeated annually it would be well if the organisers of these shows would make some effort to improve matters. Ed.]

ASTER SUB-CÆRULEUS.—With reference to your illustration of *Aster sub-cæruleus* in a recent issue, we should like to say that we showed this plant in fine condition before the Royal Botanic Society on June 7 last, when it received a First-class Certificate. *R. Wallace & Co., Colchester.*

KEW NOTES.

THE NYMPHÆA-HOUSE.—This is always a great attraction to the numerous visitors throughout the summer months, and the many curious and beautiful plants grown therein are a source of much wonder, more especially so the curiously shaped Gourds, there being many enquiries as to their utility for culinary purposes.

Although the house was quite empty and in the hands of the painters until the middle of March, it is now well furnished with a great variety of plants, some of the climbers having made 30 to 50 feet of growth, and the numerous aquatic plants have been in their full beauty for some time. *Nelumbium speciosum* is now a mass of foliage, with a good crop of flowers developing; some of the leaf-stalks are 7 feet in height, surmounted with large handsome peltate blades. Other tall-growing aquatics are *Æschynomene indica*, with pithy stems 10 feet in height; *Hydrolea spinosa*, with tall spiny stems and masses of small bright blue flowers. *Thalia Schumanniana* is a new Maranta-like plant which promises to make a fine specimen. *Lasia heterophylla* is an interesting Aroid, with a slender red-black spathe, which succeeds well under aquatic conditions. Amongst the smaller plants in the tanks, *Hydrocleis Comersoni* is very beautiful with its floating leaves and large bright yellow *Enothera*-like flowers; and also *Heteranthera reniformis*, with small white stellate flowers. Amongst the other aquatics grown are *Pistia stratiotes*, *Cabomba caroliniana*, *Neptunia oleracea*, *Vallisneria* (male and female), and *Limnobium bogotensis*.

The Nymphæa-tank is in very good condition just now, the flatness of the Nymphæas being relieved by *Sagittarias*, *Pontederias*, the giant Papyrus, and also by the large pans of *Hedychium* grown near the edge, many of which make growths 8 feet in height. *H. spicatum*, *H. elatum*, and *H. coronarium* are amongst the kinds that are grown. *Nymphæa gigantea* occupies the centre of the water, its large blue flowers being the finest of all blue Nymphæas. Other species, hybrids, and varieties now flowering are *N. Omarana*, *N. Deania*, *N. pulcherrima*, *N. Rudgeana*, *N. flava*, *N. Lotus*, *N. L. rubra*, *N. L. dentata*, *N. L. devoniensis*, *N. L. thermalis*, *N. stellata*, *N. s. cœrulea*, *N. s. cœrulea* "Berlin variety," *N. s. zanzibarensis*, and also *N. s. zanzibarensis* var. *rosea*. The plants growing in the border round the house are too numerous to mention; the most conspicuous are probably the groups of bright-coloured *Acalyphas*. Others worth special notice are *Dyschoriste Hildebrandtii*, *Eranthemum tuberculatum*, *E. variegatum*, *Oxalis Ortgiesii*, *Sanchezia nobilis*, and *Astrochilana ugandensis*, which is a new species from Uganda.

Perhaps the most striking of the Cucurbitaceae are *Lagenaria enormis*, the Bottle-Gourd; *Trichosanthes anguina*, the Snake-Gourd; *Luffa ægyptica*, and *Benincasa cerifera*, which has a large fruit the shape of a Vegetable-Marrow, with a white, mealy surface covered with stiff hairs; *Dioscorea prehensilis* is a rapid climber with a curtain of growth 50 feet in length. The root-stock is the most extraordinary part of the plant; it has large tubers at the base enclosed in a network of strong roots, which are covered with very stiff spines, apparently Nature's protection of the tubers from burrowing animals. *Solanum pensile* is one of the most showy amongst the climbers with its large, pendent panicles of dark blue flowers. *S. Wendlandi* and *S. Seafortianum* are also grown on the roof. *Vitis pterophora* is a very beautiful species with stems 40 feet in length and red, aerial roots growing down to the ground. In the porch may be seen a border of the fine *Impatiens Holstii* [figured in our issue for July 1], bushy plants 1½ foot in diameter, and flowering very freely. It should become one of the most popular of greenhouse plants when more widely known. *W. H.*

SOCIETIES.

THE ROYAL HORTICULTURAL. SUMMER SHOW AT CHELSEA.

JULY 11, 12, 13.—The second summer Exhibition of the Royal Horticultural Society has this season been held in the grounds attached to the Royal Military Hospital, Chelsea. Until three years ago, exclusive of the ordinary fortnightly meetings, the Society held but one great show in the Temple Gardens, but since that time, from the courtesy of the owner, there have also been displays in Lord Hechester's park at Holland House, Kensington. Suitable and delightful as Holland Park is for the holding of such a show, it has been evident during the present week that the Chelsea Hospital grounds are equally so. It was a pleasant revelation to many of the visitors to learn that there are so many acres of grass, large trees, and shrubs in the heart of Chelsea as are contained in these grounds and in the adjoining Ranelagh Gardens.

In order to give an idea of the extent of the exhibition, we may say that, according to Mr. Wright, who had the management of the show, the area covered by the five tents was 2,400 square feet more than is available for the purpose in the Temple Gardens. The exhibition at Chelsea was a decided success, apart from financial considerations, of which we know nothing, although it can hardly be said that there were any novelties of outstanding importance.

The ORCHID COMMITTEE recommended Awards, including two First-class Certificates and two Awards of Merit, and the FLORAL COMMITTEE seven Awards of Merit.

At the luncheon offered to the Committees and Judges speeches were made by Sir Trevor Lawrence (who said the Society had now 9,200 Fellows), Sir George White, Mr. T. Challis and Mr. George Paul.

We are indebted to the Sécrétaires, also to Mr. Frank Reader and the rest of the Society's officials, for the courtesy shown us on this and similar occasions.

Orchid Committee.

Present: Norman C. Cookson, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Secretary), De B. Crawshaw, J. Gurney Fowler, F. Sander, J. Colman, H. J. Chapman, H. T. Pitt, W. Cobb, F. W. Ashton, W. H. Young, W. H. White, A. A. McLean, H. A. Traey, G. F. Moore, W. Doxall, W. Thompson, R. G. Thwaites, H. Little, T. W. Bond, R. Brooman-White, W. Bolton, and H. J. Veitch.

The Orchids occupied one side of the central staging in the large tent.

JEREMIAH COLMAN, Esq., Gatton Park, Reigate (gr., Mr. W. P. Bonnd), staged the first group, a very fine display, and excellently well arranged. From the back the long twining spikes of large yellow flowers of *Oncidium macranthum* were arching forward among sprays of *Asparagus scandens*, some hundred feet of this graceful festooning being used. In the middle was a neat and attractive arrangement of white *Cypripedium niveum*, together with bright tufts of British Orchids, a novel feature. Among them were *Orchis pyramidalis*, *O. maculata* and *Ophrys apifera*. Behind them and beneath the sprays of *Oncidiums*, was a good selection of *Pitheche* plants, including *Nepenthes Mastersiana* × *N. Curtisii*, *N. Hookeriana* × *N. Curtisii*, and other *Oncidiums*, the best being *O. crispum* Mary Coleman, a fine white flower with a large purple blotch on each segment. Others noted were *O. × Wilekanum* Rothschildianum, good *Epidendrum prismatocarpum*, *Phalenopsis Rimestadtiana*, *Miltonia vexillaria alba*, bright *Masdevallias*, *Lælio-Cattleya* × *Canhamiana alba*, *L.-C. × Wilsoni*, *L.-C. × Sunrise*, *Cattleya Mendeli*, *C. Warscewiczii*, *Miltonia Warscewiczii*, *Dendrobium* × *Cassiope*, *Bulbophyllum harbigerum*, &c. At each end were arrangements of the orange-scarlet-coloured *Epidendrum* × *Boundii*, which is almost perpetual-flowering.

MESSRS. CHARLES-WORTH & CO., Heaton, Bradford, had a very fine group of considerable variety, but chiefly hybrids. Two of the finest were a grand dark-coloured form of *Lælio-Cattleya* × *Dominiana* and an equally fine *Cattleya* × *F. W. Wigan*. The centre of the group was made up of a fine selection of *Lælio-Cattleya* × *Aphrodite*, *L.-C. × eallistoglossa*, *L.-C. × Canhamiana* and other *Lælio-Cattleyas*, *Cattleya Mossie Reineckiana* and *C. M. variabilis* were

very fine; *C. Eldorado alba* and other *Cattleyas* good and well bloomed. The best of the *Cypripediums* was *C. × Daisy Barclay* (Godfroyæ leucocheilum × Rothschildianum), a fine white flower with claret-purple lines. Other good things were *Brasso-Cattleya* × *Helen*, *Phalenopsis violacea*, *Odontoglossum* × *Othello*, *O. × Rolfeæ*, and other hybrid *Odontoglossums*; *Ornithocephalus grandiflorus*, *Oncidium macranthum*, *Brassia Gireoudiana*, *Zygotetulum xanthinum*, *Lælio-Cattleya* × *Lucilla* var. *dulsis*, a pretty yellow flower; and a very remarkable generic hybrid named *Schom-Cattleya* × *spiralis* (*Schomburgkia tibicinis* × *C. Mossie*). The growths much resembled a stout *Lælio-Cattleya* × *Schilleriana*, with two to three ovate, hard leaves at the top. Inflorescence produced like that of *Schomburgkia*, with a cluster of flowers at the top of a stem 18 inches long. Sepals and petals narrow, twisted, rose-coloured. Lip three-lobed, the side-lobes folded over the column, middle lobe ovate, rolled back on the basal part. Base of lip white, front rose-purple.

MESSRS. SANDER & SONS, St. Albans, had a very fine group, in which their superb strain of *Lælio-Cattleya* × *Martinetii* formed the salient feature. A great many varieties were staged, some with rose-coloured sepals and petals and purple labellums, after the manner of the original form, but the greater part having bronzy-yellow and reddish-rose sepals and petals and purple labellums veined with claret colour. Some of the best were *L.-C. × Martinetii Flambeau*, of the orange-tinted class, and for which a First-class Certificate was awarded to Messrs. Sander, June 25, 1902. *L.-C. × Martinetii tesellatum* had chrome-yellow sepals and petals, and purple lip edged with lilac, and resembled the *L.-C. × ochracea*, for which an Award of Merit had been given previously to Messrs. SANDER. *L.-C. × Martinetii splendens* was the largest of the bronze-tinted section. Among the forms of *L.-C. × Canhamiana*, *L.-C. × C. Vulcan* was a very large mauve-coloured flower with intensely dark purple lip. *Cattleya Warscewiczii* "Our Queen" and *C. Mossie Reineckiana* (see Awards) were distinct varieties; *C. M. Reineckiana vestalis*, a pretty white variety with a violet tint on its white-edged labellum; and *Miltonia vexillaria Empress Augusta*, *M. × Bleana*; a noble plant of *Vanda cœrulea*, with three spikes; *Cattleya Warscewiczii Sanderæ*, a richly coloured form of *C. W. saturata*, and without the light colour seen on the lip of other forms; and other good Orchids were included, the whole being well arranged with Maidenhair Ferns.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), followed with a neat group of good things, among which were the very beautiful *Zygotetulum* × *Roebliangianum*, now grown into a very fine specimen; two examples of *Phalenopsis violacea Schröderiana*, with flowers almost entirely of a rich carmine-rose, and seemingly very distinct from the typical *P. violacea*; *Miltonia vexillaria rubella*, *M. v. superba*, *Cypripedium superbiens*, *C. Curtisii*, *C. callosum Sanderæ*, *C. × Gowerianum magnificum*, *C. concolor Sanderæ*, *C. × Cymatodes*, and other *Cypripediums*; *Lælio-Cattleya* × *Hippolyta langleyensis*, *L.-C. × H. Phœbe*, fine *Cattleya Mendeli*, *Sophro-Cattleya* × *Chamberlainiana*, various *Oncidiums*, &c.

MESSRS. HUGH LOW & CO., Enfield, completed the side by arranging at the end a very effective group in which were excellent forms of *Cattleya Mossie*, *C. Gaskelliana*, and *C. Mendeli*, one fine specimen of *C. Mendeli* bearing twenty-one flowers; *C. bicolor Grossi*, *C. Leopoldi*, and other *Cattleyas*. At one end was a selection of the orange-coloured *Epidendrum vitellinum*, in the middle several good specimens of the fringed-lipped *Brassavola Digbyana*, and at the other end a selection of pretty *Masdevallias*, including *M. muscosa*, *M. Schroderiana*, *M. ochthodes*; also *Calanthe veratrifolia*, *Bulbophyllum Dearei*, *Epidendrum prismatocarpum*, *Lycaste tricolor*, the fine *Cypripedium* × *I'Ansoni* with three flowers, *C. Stonei*, *C. niveum*, *Oncidium earthaginense*, *Phalenopsis Sanderiana*, *Lælio-Cattleya* × *C. G. Roebliang* and other showy kinds.

Awards.

FIRST-CLASS CERTIFICATE.

Cattleya Mossie alba Tracy's variety, from NORMAN C. COOKSON, Esq., Oakwood, Wylam, Northumberland (gr. Mr. H. J. Chapman).—A very finely-formed pure white flower with chrome-yellow disc to the lip. The plant was given an Award of Merit, June 28, last year, and a discussion then took place as to its being a form of *C. Gaskelliana*. The question arose again, but a large majority of the Committee supported the continuation of the name originally given. It is one of

the finest of white *Cattleyas*, and much freer-growing than *C. Mossie* usually is.

Cattleya Mossie Reineckiana excelsa, from Messrs. SANDER & SONS, St. Albans.—Flowers large and finely shaped, the petals being broad, and both sepals and petals pure white. The front lobe of the lip was beautifully marked with ruby-crimson with a clear violet shade over the surface, the crimped margin white. A very handsome flower.

AWARDS OF MERIT.

Cattleya Warscewiczii "Our Queen," from Messrs. SANDER & SONS, St. Albans.—A "white gigas" of the same class as that figured in *Lindnia*, vol. x., as *C. Leopold II.*, though the plant was not vigorous enough to show at its best. Sepals and petals pure white; lip purplish-rose with the usual light patches, one each side at the opening of the tube.

Bulbophyllum Lobbii colossum, from WALTER COBB, Esq.—A very large form of the fine old species. It was first shown by F. W. Moore, Esq., Curator of the Royal Botanic Gardens, Glasnevin, Dublin, July 23, 1895, and now again by Mr. Cobb in an enormous specimen with some forty flowers, the noble plant also securing a Cultural Commendation. Scape one-flowered. Flowers over 4 inches across, buff-yellow, faintly marked with purple. Lip hinged. Dr. Lindley mentions the original form as *Bulbophyllum Lobbii* in the *Gardeners' Chronicle*, 1847, p. 423. "How fine a plant of its kind this is may be surmised by its having been taken for a *Culogyne*." Native of Java.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. C. R. Fielder, W. Bain, G. Reuthe, R. C. Noteutt, W. P. Thomson, H. J. Cutbush, J. W. Barr, C. J. Salter, Jno. Green, Jno. Jennings, H. B. May, Chas. Dixon, M. J. James, Jas. Walker, Chas. Jeffries; Geo. Paul, R. Hooper Pearson, W. G. Baker, J. F. McLeod, and Arthur Chapman.

ROSES.

MESSRS. PAUL & SON, the Old Nurseries, Chesbunt, contributed a pleasing display to the Rose section, having a well-arranged group in one of the corners of the large tent. The whole of the flowers were cut specimens, some in vases, others in epergnes, while tall sprays of the pillar varieties were accommodated in pails of water. The new H.T. *The Dandy* was included; there were also such grand varieties as *A. K. Williams*, *Ulrich Brunner*, *Mrs. W. J. Grant*, *Duke of Edinburgh*, *General Jacqueminot*, *Cherry Ripe*, *Papa Gontier*, &c., forming altogether an admirable display.

MESSRS. WM. PAUL & SON, Waltham Cross, Herts, staged a beautiful collection of Roses, all cut flowers. There were baskets of such handsome varieties as *Le Progrès*, of apricot-yellow colour; *Celia*, a pleasing rose-pink shade, and of very free-flowering habit; *Earl of Warwick*, H.T. *Prince de Bulgarie*, *Countess Cairns* (new), *Louis van Houtte*, one of the best dark-coloured Roses; *A. K. Williams*, of most perfect form; *Frau Karl Druschki*, &c. The whole was arranged with great skill and taste.

MESSRS. HOBBIES, Ltd., had a nice lot of cut Carnations, arranged in vases; also a very showy exhibit of cut Roses, in a number of varieties. A new bedding *Coleus* exhibited by this firm, and named *Ruby Gem*, has long, narrow, fimbriated leaves of purple colour with a little red colour in the centre.

MESSRS. GEO. JACKMAN & SON, Woking Nursery, Surrey, made a magnificent display with cut Roses, showing single blooms of exhibition varieties, and gorgeous bunches of decorative sorts.

MESSRS. WOOD & SON, Woking, and Tongham, Surrey, showed flowers of a Rose named *Mrs. Neate*, a pink-coloured H.T. that may prove to be of merit.

Mr. G. H. F. Nye, Grosvenor Floral Dépôt, 39, Chapel Street, Belgrave Square, exhibited bunches of *Roses*, *Liliums*, *Sweet Peas*, &c., designated as flowers for table and decorative purposes.

MESSRS. W. CUTBUSH & SONS, Barnet Nurseries, and Highgate, London, N., exhibited a grand lot of cut specimens of the new pink-flowered Rambler Rose, named *Mrs. F. W. Flight*, a variety that has been already eulogised in these columns.

STOVE AND GREENHOUSE PLANTS.

MESSRS. WM. BULL & SONS, King's Road, Chelsea, contributed a collection of ornamental stove and greenhouse foliage plants. Several good specimens of *Dracæna Victoria* were prominent, alternating with plants of *Pandanus Veitchii*. Plenty of colour was furnished by such subjects as *Dracænas*, *Caladiums*,

Codiaeums (Crotons), Phyllanthus nivosus, &c. Nidularium Innocenti striatum was staged well. Palisota Barteri was shown in fruit, the bunch of red capsules being conspicuous. Tillandsia Zahnii was in flower. Tree-Ferns found a place in the collection at the background.

Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, exhibited a collection of highly coloured Codiaeums, representing selected varieties, also plants of Medeola asparagoides var. myrtifolia; a group of well-flowered Bouvardias, and plants and flowers of Tree and Souvenir de la Malmaison Carnations.

Messrs. JOHN LAING & SONS, Forest Hill, London, N., put up a batch of Caladiums. The plants were very finely coloured, although perhaps not so large as they are shown at the Temple Flower Show. The following were notable varieties in the collection:—Colonel John Hay (see Awards), Mrs. Laing, Madame Schmidt, Alexander III., l'Insolite, Silver Cloud, Rio de Janeiro, Joseph Cremazy and Marquis d'Albertas.

Messrs. J. PEED & SONS, West Norwood, London, brought a collection of Caladiums in most of the handsomer varieties. The foliage was not of large size, but the colours were well developed. Some of the finer specimens were Oriflamme, C. E. Dable, Marquis d'Albertas, Icaris, Diamantina, Emil Neubert, &c. The same firm also made a good display of Gloxinias and Streptocarpus, which side by side with decorative plants interspersed amongst them produced a very good effect.

Messrs. W. & J. BROWN, Stamford and Peterborough, exhibited a group of plants of Trachelium coeruleum in flower, also cut Roses, a group of Pelargoniums representing their "Cactus" strain, Verbenas Miss Willmott and a variety named Heliotrope, and other plants.

FERNS.

Although only two exhibitors staged Ferns, they constituted an interesting feature of the show, and we have never seen them shown better. Mr. H. B. MAY, Upper Edmonton, filled one side of the centre stage in the large tent with a superb collection. There were upwards of 300 species and varieties, all the choicest sorts being represented in clean, healthy plants. A large number of choice things might be enumerated. The Adiantums included fine specimens of Farleyense, macrophyllum, peruvianum, rubellum, and other tinted varieties; Aspleniums of the Pterioides type; cicutarium, Polypodium Mayi, Schneideri, and many of the small-growing sorts on stems. The choice Davallias and the American varieties of Nephrolepis were features.

Messrs. HILL & SON, Lower Edmonton, made a grand show with a group which occupied over 830 square feet on the ground in the large tent. The background was made up of grand specimens of the larger-growing Ferns, and round the front were many beautiful and choice sorts. The tinted varieties are always a feature with this firm, and many of the Adiantums were beautifully coloured; also Lomarias, the Platyceriums, especially angolense and Veitchii, were grand. Davallias of the filipensis varieties were very fine, also Nephrolepis Fosteri. This variety varies considerably, but as shown by Messrs. HILL it is one of the prettiest we have.

CARNATIONS AND SWEET PEAS.

Messrs. PEED & SONS, West Norwood, London, S.E., exhibited a collection of Malmaison and Tree Carnations. A row of the yellow variety Cecilia at the back contrasted well with the Asparagus, &c., used. Lady Rose is a good rose-coloured "Malmaison," Lord Milner is a good scarlet variety. There was a batch of the white border variety Hildegarda, which is one of the best white varieties. Agnes Sorel is of rich dark crimson colour. The border variety M. C. Higgs resembles a "Malmaison" variety both in colour and in size.

Mr. Phillips, gardener to E. WAGG, Esq., The Islet, Maidenhead, staged an excellent group of Carnations all of the "Malmaison" type. The yellow variety Cecilia was prominent. There were in addition good specimens of Sir C. Freemantle (scarlet-pink), Mrs. Martin Smith, Nautilus, Calypso, Princess of Wales, &c.

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., exhibited a group of Carnations in pots, chiefly of Souvenir de la Malmaison and "tree" varieties.

Mr. J. DOUGLAS, Edenside Nurseries, Great Bookham, staged a collection of very choice border Carnations, one variety being given an Award of Merit;

Lady Dartmouth (of salmon-yellow colour), and Carabas (pink) were also very fine.

Mr. J. R. BOX, West Wickham, Kent, put up a mixed group, comprising Carnations, excellent tuberous-rooting Begonias, Hydrangeas, Trachelium coeruleum, with foliage plants, Caladiums, Begonia Rex, Palms, &c. Several new Begonias were included, among them we admired the rich scarlet colour of the variety Miss Stuart.

Messrs. WM. CUTBUSH & SON, Highgate, London, N., staged a charming group of flowering plants in one corner of the large marquee. The general design consisted of banks of flowers, Roses, Hydrangeas, Carnations, Verbenas, Lantanas, &c., toward the back, with a groundwork of dwarf-growing Roses, Verbenas, Ericas, &c., interrupted with clumps of Carnations and standard plants of Lantanas. Maidenhair Ferns were freely used, while tall Palms gave suitable relief at the background. The display was much admired.

A group of "Malmaison" Carnations in large pots was staged by Mr. Goatley, gr. to Lady HARMSWORTH, Sutton Place, Guildford. The varieties Princess of Wales and Churchwarden were represented in about equal numbers. The plants were well grown, but the manner of staging was too formal and flat to produce the best effect.

Messrs. JONES & SONS, Shrewsbury, staged Sweet Peas and Carnations. The Sweet Peas represented about seventy varieties. Some good Carnations were shown by Messrs. JONES.

Mr. CHAS. W. BREADMORE, Winchester, staged a display of Sweet Peas in about sixty of the best varieties in cultivation, having the flowers in first-class form.

Mr. A. F. DUTTON, Iver, Bucks, showed Carnations in his usual superb style, using for the purpose handsome glass receptacles. A vase contained five most perfect flowers of the Malmaison variety Sault. When we mention that such varieties as Harlowarden, Mrs. Thos. Lawson, Enchantress, Harry Fenn, Floriana, and Fair Maid were included, each shown to perfection, some idea may be gained of the beauty of this exhibit. Adjoining were specimens of the "Shasta" or "Moon" Daisy, also shown by Mr. DUTTON.

Messrs. J. KING & SONS, Coggeshall, brought a small display of Sweet Peas, some of which were arranged in the Bruce flower-holders.

Messrs. H. CANNELL & SONS, Swanley, Kent, exhibited a collection of Sweet Peas arranged prettily in vases, with plenty of Pea foliage amongst them, also a collection of Cactaceous plants, remarkable for the very healthy condition in which the different plants were shown. Pilocerus senilis (Old Man's Cactus) was represented by half-a-dozen specimens; Euphorbia grandiformis was a most vigorous plant; Cereus flagelliformis cristata (the Rat's-tail Cactus), grafted on the night-flowering Cereus, was evidently growing well; Euphorbia caput-Medusa was very fine, also Echinocactus Emoryi (the Fish-hook Cactus), E. Grasoni, E. saglionis (in flower), Cereus peruvianus monstrosus, minor, &c., all the plants being in excellent and vigorous condition showing good cultivation. A small group of selected varieties of Cannas was shown by the same firm, and those flowers were as rich in colour and brilliant as ever.

Messrs. R. H. BATH, Ltd., The Floral Farms, Wisbech, exhibited Sweet Peas well, also blooms of Carnations and bunches of Roses.

Messrs. JAS. CARTER & CO., High Holborn, London, showed Sweet Peas arranged in large glass stands, as well as in smaller glasses. They were of good quality and very effective.

Messrs. G. STARK & SON, Great Ryburgh, Norfolk, exhibited a collection of Sweet Peas, including some novelties.

Messrs. GILBERT & SON, Anemone Nurseries, Dyke, Bonne, Lincolnshire, showed bunches of Sweet Peas neatly and attractively disposed in glasses, the Pea flowers themselves being of considerable merit.

Mr. W. J. UNWIN, Histon, Cambridge, exhibited varieties of Sweet Peas, disposed very tastefully in vases, with no grasses or Gypsophila, or anything else but the natural foliage of the plant—and this is generally all that is necessary to relieve the colour of the flowers.

Mr. H. J. JONES, Rycroft Nursery, Hither Green, Lewisham, staged collections of Sweet Peas, zonal Pelargoniums, tuberous-rooting Begonias, Nicotiana Sanderi, and forms of Chrysanthemum maximum—the Moon or Shasta Daisy. The Sweet Peas made a bold show; we noted such newer varieties as Gladys Unwin, King Edward VII., Bolton's Pink, Lady Aberdare, Remolo Piazani, Dora Breadmore, &c.

TUBEROUS-ROOTED [BEGONIAS.]

Messrs. THOS. S. WARE, Ltd., Feltham, Middlesex, had a group in which two varieties were selected for awards. The following plants were also of much merit:—Lord Rosebery (bright crimson double), In-victa (salmon-pink), W. G. Valentine (scarlet), Duchess of Portland (having shades of salmon, yellow, and rose colours), and Lady Coventry (pink with white margin to the petals). The same firm exhibited a collection of cut Roses.

Messrs. BLACKMORE & LANGDON, Twerton-on-Avon, Bath, made a magnificent exhibit, in which the general quality was very high, especially from the point of view of colour. That named J. Hooper, for instance, was of the most brilliant scarlet; it possessed fine, broad petals, a little fimbriated, and only open to criticism at all from the point of view of form, as form is understood by the florists. Mrs. W. J. Neal (double white), Mrs. J. B. Blackmore (double pink, very fine), Amy (of rosy-salmon colour), Dr. Crook (of deepest crimson colour), J. Crooks (of apricot-yellow colour), and Hilda Langdon (pale pink), were amongst the very best of an unusually fine collection.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., arranged a pretty exhibit of tuberous-rooted Begonias in which single and double-flowered varieties were about equally represented. In the centre of the exhibit was a group of plants of a good new white double-flowered variety named Miss Willmott. A single flower named Fringed Beauty was also worthy of remark. In colour it is pink, and the petals are well fimbriated. The same firm exhibited a group of well-grown crimson-flowered Gloxinias.

Mr. A. LL. GWILLIM, Eltham, Kent, also exhibited Begonias and cut flowers of Gloxinias.

HARDY PLANTS.

Hardy plants were as usual a great and attractive feature, many firms bringing displays of the best flowers in season.

Messrs. WALLACE & CO., Colchester, had a very fine display of these flowers set out in an excellent manner. One side of the exhibit was in the nature of a water-garden forming an adjunct to a rock-garden. It contained many of the best hybrid Water-Lilies, apparently quite at home. The margin of the pond was delightfully set off with Iris levigata, Spirea palmata, and other plants of a moisture-loving nature. Messrs. WALLACE also contributed Calochortus, Lilies in great quantities, and other such good things as Romneya Coulteri, Funkias, Day Lilies, Eryngiums, &c. One item of excellence was a brilliant lot of Calochortus clavatus having rich golden-yellow flowers, each measuring 4 inches in diameter.

Similar in many respects to the above was the group of hardy plants arranged by Messrs. WM. CUTBUSH & SONS, Highgate. This group was richer in Water-Lilies, and included many fine groups of hardy Sarracenias, S. flava, S. Drummondii, and others. The margin was planted with Iris levigata, Adiantum pedatum, groups of Spirea palmata, and Astilbes in variety. There were in addition excellent masses of Liliun Henryi, L. excelsum, Funkias, Hemerocallis citrina, H. Thunbergi, together with Campanulas, Phloxes, and other things. Some very fine examples of Liliun auratum virgale were in this group.

Messrs. PAUL & SON, Old Nurseries, Cheshunt, showed hardy cut flowers, in which Phloxes in variety, Potentillas, Gaillardias, Campanulas, and a host of other showy subjects were displayed to advantage.

Mr. GEO. REUTHE, Keston, Kent, staged a mixed group of plants, in which such semi-hardy shrubs as Embotrium coccineum, Rhododendron cinnabarinum, and others appeared. Masses of Alstromerias, a large assortment of Ixias, Andromeda (Zenobia) speciosa, Primula capitata, (Enothera Arendi (a rose-coloured flower, not unlike O. speciosa rosea in colour), Campanula Hendersoni, C. G. F. Wilson, and others.

Messrs. B. S. WILLIAMS & SON, Holloway, N., contributed a varied assortment of cut flowers, including Iris, Achillea, Gaillardias, Campanulas and a small collection of early Gladiolus.

Messrs. G. & A. CLARK, Dover, had a fresh-looking group of these flowers, in which Iris aurea, I. Monnierii, Alstromerias in variety, Eremurus Bungei, Centaurea ruthenica, Campanulas, some of the earlier Sun-flowers, Poppies, Heucheras and the like were prominent.

THE CRAVEN NURSERY, Clapham, Yorks, had much that was interesting in a very compact group. The dwarfed Campanulas, as G. F. Wilson, pulloides and pulla, were in plenty. We also noticed C. Van

Houttei. *Wulfenia carinthiaca* was also noted; its blue flowers are ever welcome.

A very extensive exhibit of hardy things was arranged by Messrs. BARR & SONS, Covent Garden. Here we noted many fine spikes of *Acanthus mollis* and *A. spinosus*, *Galega officinalis compacta*, the white perennial Pea, early *Phloxes*, *Helenium cupreum*, a large array of *Delphiniums*, masses of white and nankeen *Lilies*; also *Lilium Brownii* in fine condition. The Maryland Worm-grass, *Spigelia marilandica*, develops more or less tubular flowers, the tube being of a crimson colour. Early *Gladiolus* were abundant and good.

Mr. AMOS PERRY, Winchmore Hill, had a display of hardy flowers, in which *Lilies* were a strong feature. We noted *L. Browni*, *L. colchicum*, *L. excelsum*, *L. Martagon dalmaticum*, *L. canadense*, *L. pardalinum*, *L. auratum*, *L. Hansonii*, and *L. speciosum* among others. Early *Gladiolus*, *Pinks* in variety, *Platycodon Mariesi* and *P. autumnale*, *Heleniums*, notably *H. cupreum*, were all conspicuous. Varieties of *Water-Lilies* in trays were good.

St. Brigid Anemones and others, such as *King of Scarlets*, *King of Salmons*, and *Sir J. Paxton*, of rosy-mauve colour, formed the chief subjects in an exhibit staged by Messrs. REAMSBOTTOM & CO., Gleashill, King's County, Ireland. The blossoms were of excellent form, rich and telling in their variety.

Early *Gladiolus* in a large number of varieties came from Mr. WM. DULL, Chelsea.

Messrs. GEO. BUNYARD & CO., Maidstone, brought an extensive exhibit of cut hardy flowers in great variety, including such good things as *Centaurea ruthenica*, *Helenium pumilum magnificum*, the white perennial Pea, the pale-blue *Scabiosa caucasica*, *Monarda didyma*, *Galega Hartlandi*, *Iris aurea*, *I. Monnieri*, *Lilium candidum* and others. The examples in the majority of instances being cut with nearly full-length stems, gave an excellent idea of their merit and decorative worth in the garden.

Mr. N. LEWIS, Bridgewater, staged a small collection of hardy flowers, chiefly in the cut state.

Mr. B. LADHAMS, Shirley, Southampton, group was strong in *Pinks* and *Gaillardias*, *Heucheras*, *Galega Hartlandi*, *Day-Lilies*, *Campanula celtidifolia alba* (very fine), *Eriogonum macrocarpa*, *E. speciosa* (a profuse flowering plant, the pure white blossoms being of large size).

Mr. M. PRICHARD, Christchurch, Hants, brought a meritorious group of cut flowers. *Phloxes* were very fine, the intensely-coloured variety *Coquelicot* being especially prominent; *Iris Kämpferi*, *Spirea palmata* (unusually brilliant in colour), *Gaillardias*, *Acanthus*, *Pyrethrums*, *Eryngiums*, *Campanulas*, were all noteworthy and good.

Quite one of the best exhibits of cut flowers was constituted by the eighteen varieties of newer *Water-Lilies* from the gardens of L. CURRIE, Esq., Minley Manor, Farnborough, Hants. The handsome blossoms were arranged in shallow pans amid their own foliage, and included such varieties as *gigantea* (the most shapely of all white-flowered kinds), *Marliacea alba*, *M. carnea*, together with such richly-coloured forms as *igneae*, *Froehelii*, &c.

Mr. JOHN FORRES, Hawick, Scotland, brought an exhibit of herbaceous *Phloxes*, *Pentstemons*, and *Delphiniums*. The *Pentstemons* were of a high-class strain, and chiefly of the lighter-coloured varieties.

The Misses HOPKINS, Mere, Cheshire, arranged a small group of hardy plants, in which *Dianthus Napoleon III.*, dwarf *Campanulas*, and *Primula capitata* were noted.

Messrs. GEO. JACKMAN & SON, Woking, staged an admirable array of hardy cut flowers, having *Pyrethrums*, seedling *Iris Kämpferi*, many *Potentillas*, *Campanula × Fergusonii* (new), *Phloxes*, *Water-Lilies*, the dainty little *Fuchsia pumila*, and others.

Messrs. T. S. WARE & CO., Ltd., Feltham, staged a number of the best hardy flowers in season. *Water-Lilies*, dwarf and tall-growing *Campanulas*, *Heucheras*, *Gaillardias*, and a host of other showy and seasonable things were seen to advantage.

MISCELLANEOUS.

Mr. R. ANKER, Addison Nursery, Napier Road, Kensington, W., exhibited berried plants of *Nertera depressa* in ornamental "bijou" pans, also tiny *Cactus* plants in pots, and several larger specimens of *Cactaceous* species.

Mr. VINCENT SLADE, Staplegrave Nurseries, Taunton, Somerset, showed cut flowers of zonal *Pelargoniums*. They represented about seventy distinct

varieties. We noticed *Lady Warwick*, *Duke of Bedford* (Scarlet), *Lord Strathcona*, *Hall Caine*, *Prince of Orange*, &c.

Messrs. BARR & SONS, King Street, Covent Garden, and Messrs. J. CARTER & CO., High Holborn, brought a number of their interesting pigmy trees.

Mr. H. B. MAY also staged a batch of zonal *Pelargoniums*, among which were noticed several of the "Cactus" type; a collection of cleanly-grown *Codiaeums* (*Crotons*) in most of the improved varieties, including *C. edmontonense* (see Awards); *C. Prince of Wales*, *C. Hawkeri*, &c.; and some excellently-flowered plants of *Ixoras* in varieties.

Awards.

AWARDS OF MERIT.

Betonica spicata robusta.—This is the name under which a very old and well-known perennial-flowering plant was exhibited. The flowers are produced in a close pyramidal spike of some 3 inches in length, and of a rosy-pink colour. The plant is of compact habit, and attains to some 18 inches in height. *Betonicas* are now included in the genus *Stachys*. From Mr. AMOS PERRY, Winchmore Hill.

Caladium Colonel John Hay.—A variety with moderate-sized leaves of bright rosy-pink colour and white blotching. Shown by Messrs. J. LAING & SONS.

Carnation "Miss Willmott".—This new seedling border variety is of most pleasing colour, which may be described as cherry-red. The flower is about 3½ inches across, of excellent form, and the petals have a smooth, unbroken outline. Shown by Mr. JAS. DOUGLAS.

Codiaum (Croton) Edmontoniense.—This is an exceedingly good *Codiaum* of the narrow-leaved type, being not more than 2 inches across at the widest point. The young leaves are coloured rich red, yellow, and green, and the older leaves red and green only. They twist prettily towards the end or for half their length. There being but few new *Codiaeums* nowadays of superior quality, this variety will be likely to meet with much appreciation. Shown by Mr. H. B. MAY.

Thalictrum Delavayi.—A very interesting species of recent introduction, growing from 2 to 3 feet high. The drooping flowers are campanulate, and produced in considerable profusion. The roundly ovate sepals are of mauve-blue colour, and in this respect quite distinct from other members of this genus. The pale glaucous foliage is somewhat sparsely produced, and in other ways it is similar to that of other species of the *Meadow-Rue* genus. From Messrs. WALLACE & CO., Colechester.

Tuberous Begonia Mrs. Arthur Paget.—This is a delightful flower, double, about 6 inches across, of salmon-rose colour, becoming paler towards the centre of the flower, which is pure white. The form is very good.

Tuberous Begonia "Water-Lily".—This variety has very broad petals, which are white with shading of green colour. The form is not of the best florist's type, but the disposition of the petals and their great breadth give to the flower an appearance somewhat suggestive of that of a *Water-Lily*. Both of these varieties were shown by Messrs. T. S. WARE, Ltd.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., chairman; and Messrs. F. Q. Lane, Jos. Cheal, J. Jaques, Geo. Woodward, W. Fyfe, H. Markham, H. Somers Rivers, G. Kelf, C. Foster, J. Willard, and Geo. Reynolds.

Collectively the exhibits, although but few in number, were in some instances remarkable for their excellence, and this most noticeable in the *Cherries* and *Plums* sent by Mr. HUDSON, gr. at *Gunnelsbury House*, Acton; the collections of *Melons* from Mr. MORTIMORE, of *Rowledge*, and the *HORTICULTURAL COLLEGE*, *Swanley*; the *Strawberries* shown by Messrs. G. BUNYARD & CO., *Maidstone*; and those shown by Mr. PETERS from the gardens of H. P. STURGIS, Esq., *Givons Grove*, *Leatherhead*.

Mr. S. MORTIMER, *The Nurseries*, *Rowledge*, *Farnham*, *Surrey*, showed a dozen fruits of a slightly ribbed, dark green *Cucumber*, 1½ foot in length, having a short neck, and regular width from end to end, and spineless. The variety was named *Aristocrat*. This exhibitor showed sixty *Melons* in variety, as well grown as possible, and in a perfectly ripe condition. Two dozen consisted of *Sutton's Best-of-All*, a large, finely netted rind; and one dozen of *Sutton's Hero* of *Lockinge*, a yellow-skinned fruit of medium size, also

finely netted; and two dozen *Sutton's Superlative*, a large fruited variety of a greenish-yellow colour, and much netted.

Mr. GEO. PENWILL, fruit-grower and nurseryman, *Totnes*, staged two boxfuls of his new *Raspberry Champion*, an oval fruit of a red colour and moderate size. Some cut canes shown of this variety were loaded with fruits in every stage of development. It seems to be a great acquisition. It does not turn dark in colour, and is therefore excellent for jam-making. The plant is stated to continue in bearing for two months.

LEOPOLD DE ROTHSCHILD, Esq., *Gunnelsbury House*, *Acton* (gr., Mr. J. Hudson), exhibited nine boxes of *Cherries* gathered from the open wall, some, as, for example, *Black Tartarian* and *Bigarreau Napoleon*, were taken from trees planted in 1850. The other varieties shown were very fine of their kind, and consisted of the mottled red-and-yellow *Emperor Francis*, *Governor Wood*, *Late Duke*, *Bigarreau de Schrecken*, *Old Bigarreau*, *Tradescant's Late Heart*, *Elton*, &c. The *Plums*, the produce of pot trees, mostly many years old, were as good as possible, and comprised *Keine Claude Du Comte Athens*, *Early Transparent*, *Kirke's*, *Jefferson*, and *Transparent*. The stand contained fruits of *River's Orange Nectarine*, *Early Silver*, and *Downton Improved*, likewise gathered from pot-trees.

Messrs. GEO. BUNYARD & CO., *Maidstone*, showed pot trees of *Peaches*, *Cherries*, *Pears*, *Plums*, *Apples*, *Figs*, *Raspberry-canes* in fruit, *Cherries* as gathered fruit, *Red* and *White Currants*, a few dishes of last year's *Apples* in an apparently well-preserved condition. Among the pot-*Cherries* there were noted *Bigarreau Napoleon*, *Black Tartarian*, *Noire de Schmidt*, and *Emperor Francis*. The *Peaches* included *Early Alexander*, *Amsden June*, and *Waterloo*. None of them were full-grown. Last year's *Apples* consisted of *Mirfitt's Seedling*, *Calville Rouge*, *Winter Peach*, *Tibbet's Pearmain*, *Belle du Bois*, and *Alfriston*. *Fay's Red Currant*, as shown, is of a dark red colour, the fruits large, and the bunches 3 to 4 inches in length. Among the *Cherries* shown in plates there were *Napoleon*, *Monstrueuse de Metz* (a handsome fruit), *Géant de Hedelfingen*, *Bedford Prolific* (a fine dark crimson), *Bohemian Black*, *Black Tartarian*, and *Frogmore Bigarreau*. A tray of *Strawberries* numbering sixteen dishes was the most interesting exhibit, all of the fruits being fine of their kind. A *cockscomb-shaped* fruit, *Givon's Prolific*, dark crimson, with embedded seeds, was highly commended; *Louis Gautier*, a white suffused pink fruit, of *cockscomb* shape, is said to be a fine prolific variety. Others consisted of *President*, *Sir Joseph Paxton*, *Dr. Hogg* (still one of the best), *Eleanor*, *Kitley's Goliath* and *Latest-of-All*. *Imperial White Raspberry* is a good, large, prolific variety; even still more prolific are *Loganberry*, a *crimson-fruited* hybrid. *Blanche Four Seasons* is a small, free-fruited, yellow variety, and *Brooke's Seedling*, a large-fruited red fruit. Of *Peas* in pod there were sixteen dishes and varieties, mostly long-podded and well filled with seeds.

H. P. STURGIS, Esq., *Leatherhead*, *Surrey* (gr., Mr. W. Peters), showed four plants of *Givon's Grove Late Prolific Strawberry*, the plants very vigorous and fruits of an enormous size. The plants had been lifted from a north border. The variety was raised in Mr. STURGIS's garden, and took an *Award of Merit* in 1901 and a *First-class Certificate* in 1902. A boxful of extremely large fruits was also shown of this variety.

THE *HORTICULTURAL COLLEGE*, *Swanley*, exhibited a collection of *Melons*, seedlings raised at the *College*. With few exceptions they seemed to consist of one strain, and in appearance they were of large size and nicely netted.

Messrs. J. CARTER & CO., *Seedsman*, 237 and 238, *High Holborn*, *London*, showed a unique collection of *culinary Peas*, every one good of its kind. The produce was taken from plants the seeds of which were sown on March 30 for the purpose of showing the various stages of maturity. Many of the varieties were nearly ripe, as in the case of *Exonian*, *Carter's Superior*, *American Wonder*, *Wm. Hurst*, *Carter's Eight Weeks*, *Carter's First Crop*, *The Dawn*, *Carter's Edward VII.*, *The Pilot*, *First Early*, *May Queen*, and *Alpha*. *Quite Content* is a variety with pods some 6 inches long and proportionately broad. A number of *Cabbage Lettuces* were shown, including their *Perpetual*, *Holborn Standard*, *Green-fringed*, and *Endive-leaved*, a variety with deeply lacinated leaves, and

good close heart. The table of exhibits was set off by small Palms embedded in blue Lobelia, and a few dishes of Sunrise Tomato were distributed about.

AWARDS MADE BY THE COUNCIL.

GOLD MEDALS.

J. Colman, Esq., for Orchids; H. B. May for Ferns; Wallace & Co. for Herbaceous Flowers and Lilies; Wm. Paul & Son for Roses; Charlesworth & Co. for Orchids; Cutbush & Sons for Herbaceous Flowers.

SILVER CUPS.

Leopold Rothschild, Esq., for a Collection of Fruits; Lady Harmsworth for Carnations; L. Currie, Esq., for Water-Lilies; Carter & Co. for Flowers and Vegetables; Geo. Bunyard & Co. for Fruit-trees and Herbaceous Flowers; Barr & Sons for Herbaceous Flowers; Ware & Co. for Begonias; Paul & Son for Roses; Sander & Co. for Orchids; T. Cripps & Son for Trees and Shrubs; G. Jackman for Roses and Herbaceous Flowers; Amos Perry for Herbaceous Flowers; W. Bull & Son for Ornamental Foliage Plants; J. Hill for Ferns; Blackmore & Langdon for Begonias; David Russell for Trees and Shrubs.

SILVER-GILT FLORA MEDALS.

Sir F. Wigan, Bart., for Orchids; Rev. Farrer for Alpine Plants; H. J. Jones for Sweet Peas, &c.; M. Pritchard for Herbaceous Flowers; L. R. Russell for Trees and Shrubs; Mr. Box for Begonias; Hugh Low & Co. for Carnations, &c.; Pulham & Son for Rockwork and Alpines; Mr. Riley for Summer-houses.

SILVER-GILT KNIGHTIAN MEDAL.

Mr. Mortimer for Melons.

SILVER-GILT BANKSIAN MEDALS.

Jones & Sons for Sweet Peas and Carnations; G. & A. Clark for Herbaceous Flowers; J. Peed & Sons for Herbaceous Flowers; J. Cheal & Sons for Herbaceous Flowers and Shrubs; A. F. Dutton for Carnations; W. Wood & Sons for Horticultural Sundries; Manifattura di Signa for Terra-cotta Garden Vases; Merryweather & Co. for Spraying and other Machines; Mr. Castle for Garden Furniture and Seats; Champion & Co. for Tubs for Shrubs.

SILVER FLORA MEDAL.

E. Wagg, Esq., for Carnations; J. Laing & Sons for Caladiums; H. Cannell & Sons for Cacti, &c.; T. Broadmore for Sweet Peas; G. Reuthe for Alpines; Hobbies, Ltd., for Roses, &c.; Messrs. Ladhams for Herbaceous Flowers; R. H. Bath, Ltd., for Sweet Peas and Roses; V. Slade for Pelargoniums; Reamsbottom & Co. for Anemones; Fromow & Sons for Shrubs; Liberty & Co. for terra-cotta vases.

SILVER KNIGHTIAN MEDAL.

Swanley College for Melons.

SILVER BANKSIAN MEDAL.

Miss Hopkins for Herbaceous flowers; H. P. Sturges, Esq., for Strawberries; B. S. Williams & Son for Herbaceous Flowers; J. Forbes for Phlox and Pentstemons; Mr. Penwill for Raspberries; Messrs. Stark for Sweet Peas; Jas. Douglas for Carnations; F. Unwin for Sweet Peas; Gilbert & Son for Herbaceous Flowers; G. Gwillim for Begonias; J. Bentley for Horticultural Sundries; Corry & Co. for Horticultural Sundries; Dollond for Instruments; Messrs. Shanks for Lawn Mowers; Mr. Dowell for Orchid Pots; Anglo-Continental for Fertilisers; Doulton & Co. for Terra-cotta Pots, &c.; J. K. King for Sweet Peas; Jas. George for Horticultural Sundries; T. Green & Son, Ltd., for Lawn Mowers; W. Herbert for Horticultural Sundries; T. Syer for Ladders and Tools; J. Williams for Table Decoration; Mr. de Luzy for Sprayers; Mr. Pinches for Plant Labels; Economic Fencing Co. for Fencing; Mr. Sage for Horticultural Sundries.

TENT CONTAINING SUNDRIES.

One large tent was entirely occupied by various articles for garden use.

Messrs. T. GREEN & SON, LTD., Southwark Street, S.E., showed lawn mowers including examples driven by motor power; Messrs. MERRYWEATHER & SONS, Long Acre, had various spraying machines, hosing ladders, &c.; Messrs. JOSEPH BENTLEY, LTD., Barrow-on-Humber, Hull, in addition to weed-killers and insecticides, displayed bones and other manures; Messrs. TABOR & CO., Duncedin House, Basinghall Avenue, London, showed manures and fertilisers; Mr. J. WILLIAMS, Baling, displayed stands for rural table decoration; Mr. GEO. H. SAGE, 71, Manor Road,

Richmond, in addition to horticultural sundries, made a feature of the Bruce flower-holders; Mr. H. PATTISON, 1, Farm Avenue, Streatham, brought examples of his horse-boots for lawns; Mr. RICHARD PINCHES, 3, Crown Buildings, Crown Court, S.E., had an assortment of tree and plant labels of most durable make; Messrs. WOOD & SON, Wood Green, London, N., had a large display of watering-cans, syringes, spraying-machines, manures, and a host of other horticultural sundries: some handsome terra-cotta vases and flower-pots were shown by MANIFATTURA DI SIGNA, Italy; Messrs. DOULTON, Lambeth, also showed garden ornaments in terra-cotta and other ware; THE LUBROSE PAINT CO., Moorgate Station Chambers, E.C., displayed samples of their specialities in paints.

OUT-OF-DOOR EXHIBITS.

Mr. DAVID RUSSELL, The Essex Nurseries, Brentwood, arranged a large, irregular group of shrubs and small trees, mostly those having variegated foliage. There were *Acer palmatum* in variety, *Thuyas*, *Ivies*, *Euonymus latifolia alba*, *Eleagnus variegata*, *Buxus*, *Aralia pentaphylla* with white-and-green leaves, *Yews*, and *Retinospora pissifera aurea*.

Messrs. THOS. CRIPPS & SON, Nurseries, Tunbridge Wells, arranged a large and imposing group of Golden Elms, *Quercus Concordia*, *Alnus glutinosa aurea*, *Vitis purpurea*, and other species; Bamboos and Japanese Acers, many of them fine specimens.

Mr. L. R. RUSSELL, Richmond Nurseries, Richmond, Surrey, showed a group consisting of similar plants differently disposed, and generally of a larger size; and the group enlivened by *Clematis* plants in bloom.

Messrs. J. CHEAL & SONS, Crawley, showed a group consisting of variegated and green Conifers, Maples, New Zealand Veronicas, *Spiraeas*, *Funkias* in variety, *Ivies*, purple Beech, and other hardy things.

Messrs. BARR & SONS, King Street, Covent Garden, London, and Ditton Hill, Surrey, showed a healthy lot of pigmy trees, mostly consisting of Conifers, in ages ranging from eighteen years to sixty years old; specimens of *Zelkova Keaki*, *Quercus*, and Acers, likewise formed a part of the group.

Messrs. W. FROMOW & SONS, Sutton Court Nurseries, Chiswick, W., showed a group of hardy trees and shrubs, mostly Japanese Maples, and set off by a few *Lilium japonicum*.

LIBERTY & CO., Regent Street, London, W., showed rustic pottery of very vigorous, not to say rough designs, modelled after early Mexican or Peruvian styles. The exhibitors call it quasi-Celtic. We noted bordering for flower-beds, vases, pans for holding plants, sundials, &c., in terra-cotta.

Messrs. DOLLOND & CO., London, showed amongst other objects in terra-cotta various sundials, many of them of great age. One was mounted on a baluster from old Kew Bridge.

A clever thermograph was shown, extremely sensitive, which indicates and registers the temperature at any moment of the day or night—a good instrument for the gardener to put into his forcing-house, simple in structure, and not liable to get out of order. A registering rain-gauge, which does not store the rain-water, but empties it when the catch trough has caught one-tenth of an inch. There were anemometer or air-measurers for use in mines, passages, &c., sunshine recorders, and other instruments of utility.

Messrs. PULHAM & SON, 71, Newman Street, London, W., exhibited a quantity of vases and pedestals, edgings, sundials, fountains, balustrades, finials in artificial stone. This firm showed specimens of their work in rockery building, furnishing the rockeries with appropriate plants.

Messrs. D. J. SYER & Co., 45, Wilson Street, Finsbury, London, and at Birmingham, showed a handy barrow containing in separate compartments tools for carpentry, smithing and glazing, fitted with a work-bench on the top. It is provided with movable handles and two wheels. There were exhibits of a useful nature for gardeners, such as a tool grinder worked by a pedal; step-ladders, hose-winders, hammers, ladders, trestles.

Messrs. ALEX. SHANKS & SON, LTD., Arbroath, and Bush Lane House, Cannon Street, E.C., exhibited two petrol motor-mowing machines, having ball-bearings for the cutter and roller-bearings on the main drum: one provided with a seat for the driver. A number of hand-mowers were also shown, one hand-mower (The 'Aledonia) with corrugated roller and adjustable handles to suit the driver was observed. It is said to be extremely easy in use.

GARDEN FURNITURE, SUMMER-HOUSES, &c.

Mr. CASTLE, Baltic Wharf, Westminster, S.W., showed a collection of garden seats, benches, folding chairs, tables made of teak wood (old ships' timber). The various articles were of a plain, substantial character, simple and without not destitute of a certain degree of elegance.

Messrs. CHAMPION & Co., 115, City Road, London, showed well-finished plant tubs, polished and varnished and bound with copper or brass hoops, and furnished with copper or wooden handles. These tubs are well adapted for use in halls, conservatories and apartments.

A water-butt nearly square in the cross-section and tapering to the top was another exhibit.

Mr. C. W. RILEY exhibited portable summer-houses in rustic woodwork, tasteful in design, and capable of containing from six to twenty persons. This exhibitor, whose address is Villa Rustica, Norwood Road, Herne Hill, S.E., showed wooden tubs and small garden-seats and settles in rustic work.

Scientific Committee.

JULY 4.—Present: Dr. M. C. COOKE, V.M.H. (in the chair); Professor Boulger, Messrs. Holmes, Saunders, Gussow, Masee, and Chittenden (Hon. Secretary).

Biota Attacked by Insects.—Mr. WORSLEY sent specimens, which Mr. SAUNDERS reported were attacked by an aphid, *Lachnus epressus*, and a species of *Diaspis* (scale insect). A large number of varieties of Chinese Conifers had been attacked and destroyed.

Pear Midge.—Mr. SAUNDERS reported as follows upon this pest:—"The Pear midge (*Diplosis pyrivora*) seems to be spreading more and more every year in this country, and unless some means can be found to check it Pears will become a rare fruit. I think it is very clear that if all fruit-growers in districts where this insect abounds would agree together on some common line of action as regards the destruction of this pest its numbers would soon be very materially lessened, and in the course of a few years it would be stamped out. These remarks apply to a very considerable number of injurious insects, which at present run riot among our crops, and which isolated attempts to check are of little use, as a fresh supply is always forthcoming from neighbours' gardens, &c. The Pear-midge lays its eggs in the blossoms before and after they open; if before, the ovipositor of the insect pierces the petals, and the eggs are laid on the anthers; if the flowers are already open, they are deposited in the ovary; in either case the young larvae find their food close at hand when they are hatched. In June they leave the fruit, sometimes before it has fallen, sometimes afterwards. They then bury themselves in the soil $\frac{1}{2}$ inch, or perhaps somewhat deeper, and become pupae, from which the flies emerge in the spring just before the flower-buds open. The best means of destroying this pest are—(1) by strewing kainit under the trees at the rate of 4 oz. to the square yard early in June, so that the grubs may fall on it; or (2) in the course of the winter remove the top soil to the depth of 2 inches, and either burn it or bury it not less than a foot below the surface, or trench the ground under the trees in the winter, which will bury the pupae so deep that the flies cannot find their way to the surface; (3) in the spring, before the time that the flies make their appearance, the ground under the trees should be rolled, so that it will make the escape of the flies more difficult through the hard soil. In orchards where grass grows under the trees it is impossible to employ these methods. In that case the grass should be thoroughly drenched with a strong solution of paraffin emulsion early in April in order to destroy the flies as they are leaving the soil, and again in June, when the grubs are leaving the fruit. If it be found that nearly the whole crop is infected, it should be gathered and burnt while the grubs are still in the fruit." [The insect was figured in our columns on May 29, 1905, p. 315. Ed.]

Interesting Orchids.—M. F. W. MOORE, V.M.H., sent the following interesting Orchids from the Botanic Gardens, Glasnevin:—

No. 1. *Stauroopsis fasciata*, a native of the Malaya, and a rare species, belonging to the distichous-leaved section. It is rarely found in collections, and is remarkable for the curious shape of the lip and the attachment of the lip.

No. 2. *Bulbophyllum sanrocephalum*, also a rather rare plant, native of the Philippines. It is remarkable for its swollen peduncle, and belongs to the clavate

group. The species in this group are closely allied, and are all characterised by the swollen flower-stalk, in which the flowers are generally sunk.

No. 3. *Bulbophyllum quadrifarium* (Rolfe). This is a new species from Madagascar, recently named and described. It is very rare, and is remarkable in having a portion of the peduncle carrying the flowers quite square, so that it has a four-sided appearance. There are numerous scales concealing the flowers. The inconspicuous flowers seem to be highly self-fertile, as a number of fruits were produced on each inflorescence.

No. 4. *Bulbophyllum erythrorachis* (Rolfe). A new species like the last two, with a long, club-shaped, red rachis.

No. 5. *Bulbophyllum infatum* (Rolfe). A new species with a curiously inflated rachis about 2½ inches long and ¼ inch in diameter, bearing numerous small greenish-white flowers.

Fasciated and Contorted Teasels.—Prof. DOULGER, on behalf of Dr. MASTERS, showed a walking-stick made from a curiously contorted Teasel stem. Professor de Vries has stated that this peculiarity can be perpetuated by seed, but after growing the seed obtained from Professor de Vries and following the directions given for at least ten years, Dr. MASTERS has failed to obtain any contorted specimens, although by continued pinching a large amount of variation may be observed in the foliage, sometimes four leaves occurring in a whorl, and so on.

Disease of Salsafy.—Mr. SAUNDERS showed a specimen of Salsafy attacked by the fungus *Cystopus tragopogonis*, very commonly found upon Goat's-beard.

Damage by Hail.—Dr. PLOWRIGHT sent specimens of Peas, Cabbage, and Apples illustrating the damage done by a recent hailstorm to these crops.

Excrecences on Tree Trunks.—Mr. BENEDICT sent an example of an excrescence on the trunk of a Poplar about 8 inches in diameter, covered with small shoots and adventitious buds, stating that similar excrescences were developed on Laburnum, Elm, and Plane. It was thought that the tree had made an effort to heal a wound made in pruning or otherwise, and that from the callus formed numerous adventitious buds had arisen, and that neither a fungus nor an insect was the cause of the trouble. The sender thought that probably too deep planting had been a contributory cause.

British Dye Plants.—Dr. PLOWRIGHT sent the following notes with specimens of the dyes described:—

1. *Hedera Helix.*—The Ivy is a plant we always regard as being one of the most sombre of our English phanerogams. I was very much astonished a short time ago to find that the ripe berries yielded, on boiling with water and a small quantity of alum, a rich reddish-purple fluid which had the property of conveying to wool a reddish tint. There are very few red colours yielded by our British dye plants. The red dye of Ivy-berries is not mentioned by Linnaeus nor by Withering, or any of the botanical writers of that period which I have read. The roots of the plant from which the berries were taken, it may be observed, show numerous stains of red. The colouration of the roots is not soluble in boiling water or in alcohol. The colour is mostly in the cortex, but extends to the outer part of the wood, old roots and rootlets both showing it.

2. *Crataegus Oxycantha.*—The Mayflower has many poetical associations, few plants have not, but it will come as a surprise to many people (but not to all) that the blossom is capable of yielding a dye. One would hardly have expected the beautiful white petals to have yielded such a deep shade of yellow as they are capable of imparting to wool when mordanted with alum.

3. *Populus nigra.*—The colouring matter contained in the male catkins of the Black Poplar was not known to the older botanists, or, at any rate, was not referred to by Linnaeus. This is possibly accounted for by the fact that it does not easily impart itself to wool, and could not be used for that purpose by any of the rough-and-ready processes then employed. My attention was first drawn to it by noticing how the foot pavements in towns were stained by the crushing underfoot of the catkins which had fallen from the tree when in bloom in spring. The stains are a bluish or bluish-green colour, and remain visible for a considerable time. The catkins, or rather the anthers, are of a brilliant red, so that the contrast is very marked. The colour yields itself freely to boiling water to which alum is added, but the salt is not sufficiently acid to produce the full deep red. Unlike most colouring matters obtained from flowers,

this red is very permanent to light. The specimen shown was made in 1902, as the label shows. It was exposed to direct sunlight in a north window until the present time. As far as my remembrance goes, it has lost little, if any, of the colour, but the ink with which the label was written has faded to such a degree as to be barely legible. The red colour is also soluble in alcohol. Linnaeus noticed other colours which, although yielding themselves to alcohol and water, were not available for tinctorial purposes, such as the red which the flowers of *Hypericum perforatum* yield to alcohol, and the green which the flowers of *Delphinium Consolida* give to solutions of alum in water. It is curious that the Poplar catkins escaped him.

4. *Lithospermum officinale.*—The old writers from Linnaeus were acquainted with the fact that the root of this plant imparts to fats, oils, alcohol, and wax a red colour. They also state that the roots were used by the young women of Sweden to impart a pink colour to their complexion. Mr. E. J. Tatum was kind enough to send me some specimens of this plant in April. The colour is confined to the cortical portions of the main roots. It is distributed in patches, which, when rubbed between the fingers, stain them red in the same manner but to a less degree than the true Alkanet-root does. The red colour imparts to solid paraffin a red tint very similar to that from the root of *Echium vulgare*. The red colouration is more abundant in the roots of *Lithospermum* than in those of *Echium*.

Exotic Spider.—Dr. PLOWRIGHT also sent a specimen of a large spider (sp. ?) which had been imported alive in a cold-storage chamber.

Strawberries Attacked by Millipedes.—Mr. SAUNDERS reported upon these as follows: "The 'beast' attacking the Strawberries is one of the 'snake millipedes,' the spotted snake millipede (*Julus guttatus*). This is a most destructive pest in gardens, since it attacks the roots of various plants. While in the soil it is almost impossible to kill them with any insecticide; but if a strong solution of common salt or nitrate of soda can be brought to bear on them it will kill them. They may be trapped by burying small slices of Mangold, Turnip, Carrot, or Potato near the plants they are feeding on, just below the surface of the soil. These traps should be examined every morning; a small skewer stuck into the pieces will show where they are buried. The millipedes appear, however, to be so fond of ripe Strawberries that I doubt if these baits would tempt them away from them. Placing straw, &c., under the fruit, as is so often done, I am sure encourages these pests."

Scale on Ash.—Mr. SAUNDERS reported:—"The insects infesting the pieces of Ash-stem are scale insects. The larger white woolly ones are female specimens of *Pseudo-coccus aceris* (Signoret); the insect itself is at one end of the ovisac, almost hidden by the wool-like matter with which the eggs are surrounded. The other insects, which look like small long white specks (only ½ mm. or 1-40th of an inch in length) are the males of *Chionaspis salicis*, an insect which is very common on the Ash, various kinds of Willow, and the Alder. The female scales are nearly twice the length of the males, and are of a more or less oval or rounded form. The best means of destroying the pseudo-coccus is by brushing off the white ovisacs, and then spraying with a strong solution of paraffin emulsion; or in the course of the winter, after the leaves have fallen and before the buds show any signs of opening in the spring, with a caustic wash. The same methods will destroy the chionaspis."

Violets Attacked by Eridium.—Dr. COOKE reported on these, received from Bournemouth: "The Violets are attacked by Violet cluster cups (*Journal of the Royal Horticultural Society*, xxvii., 1902, p. 25, pl. i., fig. 21). Plants once attacked seldom recover. As a precaution, all the infected plants should be rooted up and burnt. The residue should be sprayed with Bordeaux-mixture to preserve them from infection by any spores left on the soil. It is an endophytic parasite, and cannot be eradicated from a plant in which it has become established."

CROYDON HORTICULTURAL.

JULY 5.—This well-supported Society of gardeners, amateurs, and cottagers held its thirty-eighth summer show in the meadow adjoining Haling Park, the residence of Miss Watney, on the above date. The exhibits were numerous, and many of them good of their kind, but not of a sort which tests the cultural skill of the gardener; and fruit was almost absent.

ROSES.

Nurserymen's Classes.—In the class for forty-eight Roses, distinct, the National Rose Society's Silver-gilt Medal went with the 1st prize. In this competition,

in which there was only one exhibit, the 1st prize was worthily awarded to Messrs. D. PRIOR & SON, Colchester, for H.P.'s and Teas, and so good were the blooms individually that it would serve no good purpose to select varieties.

For twenty-four Roses, distinct, three blooms of each, 1st, Messrs. D. PRIOR & SONS, with one of the most interesting exhibit of Roses in the show, all the blooms being of perfect shape and well developed.

For twenty-four Roses, distinct, shown by those who did not compete in the two previous classes—1st, Messrs. J. R. BOX & CO., West Wickham, Croydon, and Shirley.

Forty-three-six Roses, distinct (amateurs), 1st, A. TATE, Esq., Downside, Leatherhead, with two boxes of superb flowers, the finest being Bessie Brown, which was awarded a Silver Medal. The 2nd prize fell to Mrs. HAYWOOD, Woodhatch Lodge, Reigate (gr., Mr. C. J. Salter), for very even, nice blooms, with but few weak ones amongst them, fresh looking, and only lacking a little in size to have taken the 1st place. Incidentally we heard that Reigate rosarians suffered greatly from the hard frost that occurred late in May.

For twelve Roses of one variety (amateurs), J. BRADFIELD, Esq., was 1st, with the variety Ulrich Brunner, all of which were excellent blooms, and almost equal in size. 2nd, Mrs. HAYWOOD, with Caroline Testout, in our opinion as good almost as the foregoing.

LOCAL ROSE CLASSES.

Twelve Roses distinct.—1st, E. M. PRESTON, Esq., Shirley Hurst, Shirley, with a good stand, the finest blooms being Frau Karl Druschki (Silver Medal), Caroline Testout, Marchioness of Londonderry, &c. 2nd, Lieut.-Col. J. W. JEROME, 244, South Norwood Hill.

TABLE DECORATIONS.

A large portion of the middle marquee was assigned to table decorations, and the most imposing of these was set up by Mr. T. BUTCHER, The Nurseries, South Norwood, whose exhibit consisted of Sweet Peas and Shirley Poppies.

The best exhibit of Gloxinias and ornamental foliage plants or Ferns on a table 8 feet by 4 feet. The 1st was from Mr. T. Padley, gr. to W. G. RAIFORD, Esq. The varieties were seedlings from erect, spotted, edged, and self-coloured flowers, the plants exhibiting great vigour in leaf and flower. A varied and pleasing collection. 2nd Mr. G. Barnes, gr. to S. A. READ, Esq., Hurstleigh, South Park. This exhibit and that which took the 3rd prize possessed too little variety of colour.

Twenty-four Bunches of Sweet Peas.—1st, Mr. W. Lintott, gr. to W. GREENWELL, Esq., Marden Park, with a collection of fine, well-developed blossoms in most of the newer tints. We noted Countess Spencer, Robie Sydenham, Orange Countess Mrs. Walter Wright, Janet Scott, and Scarlet Gem. The 2nd prize was taken by Mr. G. DAVIDSON, Elm Lodge, Quadrant Road, Croydon.

Groups of Plants arranged for Effect.—1st, Mr. Burdett, gr. to E. C. P. HULL, Esq., Earlswood Mount, Redhill, with a lightly-disposed group, of which the salient points were bright yellow *Codiums*, *Cordylines*, *Kalanchoes*, *Gesnera coccinea*, *Palms*, and *Caladiums*, with a groundwork of dwarf things thinly spread about.

A small collection of Cacti and Melon Cacti was shown by Mr. C. A. BLOGG, 46, Haling Road, Croydon, who was awarded 1st prize. The species shown did not include any varieties or large specimens.

AMATEURS AND GARDENERS.

Fifty Fruits of Strawberries.—1st, Mr. W. LINTOTT, gr., Marden Park; 2nd, Colonel INGLIS, Craigendown, Reigate, both showing Royal Sovereign.

Other fruit staged was not remarkable. Cucumbers were plentiful, also Peas, Broad Beans, and Tomatos.

NOT FOR COMPETITION.

Mr. J. R. BOX, Nurseryman, West Wickham and Croydon, showed a group in which tuberous Begonias formed the groundwork of small groups of scarlet Carnations, *Caladiums*, Maidenhair Ferns, Asparagus, &c.

Mr. T. BUTCHER, Nurseryman, Croydon and Shirley, exhibited Palms healthy and well-developed, also flowering decorative plants, Ferns, Lilies, *Hydrangea Hortensia*, *H. paniculata*, &c.

Messrs. THOMAS WARE & CO., Ltd., The Nurseries, Feltham, Middlesex, contributed a number of Nymphæas and a large assortment of hardy herbaceous flowers, making a very gay display.

Mr. EBENEZER POTTEN, Camden Nurseries, Cranbrook, showed Roses in single blooms and triplets, but very few were good blooms. The best were Madame Ravary, Killarney, and La France. This exhibitor set up a table of hardy herbaceous cut flowers, and among them, Eclair, a fine purple Phlox.

Messrs. J. PEED & SON, nurserymen, West Norwood, S.E., showed a table set out with Sweet Peas in great variety.

Mr. J. R. BOX contributed a small table set out with hardy herbaceous cut flowers, *Dianthus barbatus*,

Delphinium nudicaule, Verbascum Chaixii, Lychnis Haageana being uncommonly choice and good.

Messrs. G. JACKMAN & SON, Woking Nurseries, Surrey, likewise made a pretty display with hardy herbaceous plants, and amongst them some handsome seedlings of Iris Kämpferi.

Messrs. JOHN LAING & SONS, The Nurseries, Forest Hill, London, staged six dozen Rose blooms, H.P. and Tea varieties, of fine quality, hardy herbaceous flowers in some quantity, and all of them showing great vigour.

Messrs. JONES & SONS, Coton Hill, Shrewsbury, showed forty-two varieties of Sweet Peas very strong and good.

Messrs. CHEAL & SONS, Nurseries, Crawley, furnished a lot of tabling with capital cut flowers of hardy plants.

HANLEY FLORAL FÊTE.

JULY 5, 6.—The ninth annual horticultural show and fêtes, under the auspices of the Corporation, was held on these dates, and was again favoured with excellent weather. Year by year this function grows in importance and in attractiveness, and since the first show was held in 1897 no less a profit has been made than £3,260 17s. 10d. This year's show was equal to any that have been held in Hanley Park. Never before has a finer or more comprehensive display of flowers been seen in the district, and this despite a season which has not been by any means in favour of the horticulturist. The fruits made in every sense a much finer show than last year, and the wreaths and baskets of flowers also made an excellent display.

In the class for a group of plants arranged for effect, the 1st prize was awarded to Messrs. J. CYPHER & SONS, Cheltenham, who included several excellent Orchids in their display. The group staged by Mr. JAMES BLACKER, Selby, ran the 1st prize collection very close for premier honours, but it was rather heavily staged. Another good group was shown by Messrs. ARTINDALE & SONS, Sheffield.

Messrs. CYPHER also secured 1st place in the class for a group of Orchids in flower, with Ferns and other suitable foliage plants. 2nd, Mr. WM. VAUSE.

The class for a group of Malmaison and other Carnations was keenly contested: it resulted in Mr. P. BLAIR, Trentham Hall Gardens, Stoke-on-Trent, winning the 1st place, followed by Mr. JNO. SCOTNEY, Tittensor Chase Gardens, Stoke-on-Trent, and Mr. GOODACRE, Elvaston Castle Gardens, Derby.

The best stand of seventy-two distinct varieties of Roses was those shown by Messrs. J. Townsend & Sons, Worcester; and the same firm was also 1st in almost all the other classes for Roses.

The best collection of hardy perennials, occupying a space 16 feet by 4 feet, was that put up by Messrs. G. GIBSON & Co., Bedale.

The class for a dessert-table, to be decorated with flowers and foliage, and containing not more than fourteen dishes of fruits, made a pleasing feature. The prizes were valuable, the 1st, totalling 15 guineas in value, being won by Mr. J. H. GOODACRE, Derby, who was also 1st for a collection of twelve dishes of fruits, in not fewer than eight distinct kinds.

The best four bunches of Grapes, including two black and two white varieties, were shown by Mr. T. BANNERMAN, Rugeley.

DEVON AND EXETER HORTICULTURAL.

JULY 7.—The two-hundred-and-first Exhibition of the Society was held, as usual, in the charming grounds of Northernhay, Exeter's most popular pleasure-ground. Some members of the Committee, when the year's arrangements were being made, strongly advocated a Rose show, while others preferred the usual date, about the third week in August, when outdoor fruits and vegetables are at their best. The date fixed was a compromise, and the result was unsatisfactory, for it was a week or ten days too late for Roses at Exeter, and more than a month too early for fruit and vegetables. The entries prove this. There were in all 80 Classes, against 114 last year, while the entries totalled 250 against 663 last year—less than half! But for the trade exhibits the show would have been a comparative failure.

OPEN CLASSES.

Roses.—Cut Blooms, Thirty-six Distinct H.P.'s.—There were but two entries, the 1st prize going to THE DEVON ROSERY CO., Torquay; and the 2nd prize to Messrs. JARMAN & Co., Chard. The class for twelve H.P.'s, three blooms of each, falling to the same firms in the same relative positions.

For twelve distinct Teas, Hybrid Teas and Noisettes, three blooms of each, Messrs. JARMAN & Co. were 1st; and the DEVON ROSERY CO., 2nd.

For a table measuring 8 feet by 4 feet, furnished with fruit and flowers for dessert, the 1st prize was awarded to Mr. W. BROCK, Exeter (gr., W. Rowland), the only entry.

CLASSES CONFINED TO SUBSCRIBERS.

For twelve blooms of Roses on long stems, all distinct, the 1st prize went to Dr. SAMWAYS, Clyst St. George (gr., A. Williams), who staged a meritorious twelve; and was closely followed by Sir DUDLEY DUCKWORTH-KING, Weir House (gr., S. Baker), Col. HARDINGE, Exeter (gr., A. Evans), being 3rd.

The other classes for Roses were not well filled, and do not call for particular comment.

CUT FLOWERS.

The competition in this section was more spirited, and although nothing very new or rare was shown, the specimens were well grown and of considerable merit.

For twelve bunches of hardy herbaceous flowers, distinct (bulbous species admitted), Rev. E. HEATHCOTE, Reive (gr., G. Wilton), was 1st; Miss FARRANT, Huxham, 2nd; an extra prize to Col. SANFORD, Wellington (gr., Mr. Kitley).

The best exhibit of nine bunches of Sweet Peas, distinct, was shown by Mr. J. H. LEY, Trehill, 1st; Sir DUDLEY DUCKWORTH-KING, 2nd; and an extra prize to Mrs. S. P. POPE, Exmouth.

PLANTS.

The best exhibit of a group of miscellaneous plants arranged in an oval space of 10 feet by 12 feet was one from Mr. W. BROCK; Mr. T. KNAPMAN being 2nd.

For nine Gloxinias (six distinct), Mr. C. M. COLLINGWOOD, of the Institution for the Blind, Exeter, was 1st with plants of exceptional merit. Mr. J. H. LEY, Trehill, was a good 2nd.

For six double tuberous-rooted Begonias, Mr. COLLINGWOOD was 1st for well-grown plants hardly at their best.

The best exhibit of six single tuberous-rooted Begonias was shown by Mr. W. BROCK, Exeter; Mr. O. BURTON, Sowton, being 2nd.

Mr. O. BURTON won the 1st prize for six Fuchsias; and Mr. W. BROCK was 2nd, both exhibits being excellent, and near in respective merit.

FRUIT AND VEGETABLES.

For White Grapes, Rev. A. H. HAMILTON-GELL, Winstade (gr., G. Barnes), was 1st, with Duke of Buccleuch—the only entry; while Mrs. F. HEARN, Exeter, was 1st for six Peaches—also the only entry.

VEGETABLES generally were not of the usual high quality staged at this show, for reasons assigned above. The principal prize-takers were Dr. SAMWAYS, Sir DUDLEY DUCKWORTH-KING, Captain RATCLIFFE, Mr. VICKERY, and Mrs. HEARN.

TRADE EXHIBITS.

Messrs. ROBERT VEITCH & SON, Exeter, had a large miscellaneous collection in which several of the new Roses were staged, also Romneya Coulteri, in fine form; Coriaria terminalis, Lonicera Hildebrandti, Black Currant Boskoop Giant, Gerbera Jamesoni, Spiraea Aruncus Kneiffii, Polygonum Baldschuanicum, Genista æthensis, and a large collection of Sweet Peas.

Mr. W. J. GODFREY, Exmouth, showed Solanum Wendlandi, Carnations Godfrey's Pride and Reginald Godfrey; Cannas, Pelargoniums, Sweet Peas, &c.

Mr. G. KESWELL, Bowhill, Exeter, had a general collection of conservatory plants, including fine double Begonias.

Messrs. CURTIS, SANFORD & Co., Torquay (Devon Rosery Co.), had Roses (H.T.) Princess Charles de Ligny, Ligne Aremburg (H.P.), Hugh Watson, Florence Pemberton, &c.

Messrs. JARMAN & Co., Chard, showed Roses, Sweet Peas, new Sweet Sultans, and other subjects in good form.

Messrs. W. B. SMALE, Torquay; JAMES WALTERS, Mount Radford; TUPLIN & SONS, Newton Abbot; and SAUNDERS & BISS, Exeter, had special exhibits, all the trade exhibitors being awarded Certificates of Merit.

The exhibition was honoured by a visit from H.R.H. The Princess Frederica of Hanover, who was on a visit to Mr. and Mr. Byrom, of Culver, near Exeter. The Princess was accompanied by her husband, Baron von Pawel-Rammingen.

Messrs. Robert Veitch & Son and Mr. W. J. Godfrey, of Exmouth, on behalf of the nurserymen exhibiting, presented Her Royal Highness with a beautiful bouquet of pink and yellow Carnations.

ROSE SHOW AT THE CRYSTAL PALACE.

JULY 8.—The Crystal Palace Company having lost the exhibitions of the National Rose Society, have this season held one under their own management. They issued a schedule of prizes to the large amount of £225, and in the various classes very liberal prizes were offered. The schedule was an ambitious one, for it included a class for seventy-two distinct varieties, similar to the largest class in the National Rose Society's schedule.

In this competition there were as many as seven exhibitors, being more than the National Rose Society have had for some years past. The 1st prize consisted of the sum of £10, with 2nd, 3rd, and 4th prizes of £8, £6, and £5. Most of the competitors were members of the National Rose Society, and some of

them expressed pleasure at the luncheon at being enabled once again to exhibit Roses in the familiar Crystal Palace.

The show was a very good one indeed for the present indifferent season, and to the onlooker at least it would appear that in the future there will still be a Crystal Palace Rose Show.

The arrangements, &c., were in the capable hands of Mr. Geo. Caselton, Superintendent of the Crystal Palace Gardens.

NURSERYMEN'S CLASSES.

Messrs. ALEX. DICKSON & SONS, Newtownards, co. Down, surpassed six other exhibitors in the very exacting class for seventy-two blooms, distinct. Their best blooms were Killarney, Chas. Darwin, Madame Delville, Chas. Lefebvre, Mildred Grant, Chas. Grahame, Gustave Pigancan, the very lovely White Maman Cochet, Star of Waltham, Duke of Wellington, and the pink-coloured Countess Annesley. 2nd, Messrs. B. R. CANT & SONS, The Old Rose Gardens, Colchester, who won 1st prize in the similar class at the National Rose Society's exhibition. There were some very pretty flowers in this collection, among which may be mentioned Mildred Grant (capital), Golden Gate, Horace Vernet, Reynolds Hole, Mrs. Ed. Mawley, A. K. Williams, and Duke of Wellington. 3rd, Messrs. D. PRIOR & SONS, Mylands Nursery, Colchester.

Forty-eight Blooms of H.P.'s, Distinct.—In this class the winners of the 1st and 2nd prizes in the previous classes changed places, Messrs. B. R. CANT & SONS being 1st and Messrs. A. DICKSON & SONS, 2nd. The 1st prize exhibit was remarkable for containing a very large proportion of richly-coloured varieties of the Victor Hugo and Duke of Connaught types, the colours being in many instances very highly developed. The collection as a whole was composed of rather small-sized flowers. The largest and fullest flower in Messrs. DICKSON'S collection was the variety Francois Courtin. Messrs. FRANK CANT & Co. were 3rd, and Messrs. D. PRIOR & SON, 4th.

Twenty-four Blooms, Distinct.—Just as at the Regent's Park Show, Mr. CHAS. TURNER, Royal Nurseries, Slough, won the premier award in this class, and showed a collection like one previously noticed, which was remarkable for rich colours. The only white Rose in this stand was a bloom of Frau Karl Druschki, which has this season been shown very indifferently. Excluding five other blooms of various shades of pink colour, all the others were of some shades of red or crimson. The 2nd and 3rd prizes were won by Mr. JNO. MATTOCK, New Headington, Oxford; and Messrs. JNO. JEFFERIES & SON, Cirencester, respectively. There were two other exhibitors.

TEAS AND NOISSETTES.

Twenty-four Blooms, Distinct.—There were five exhibitors in the largest class for Teas and Noisettes, the 1st prize being won by Messrs. FRANK CANT & Co., who had amongst others very good blooms of Bridesmaid, Golden Gate (rather pale), Souvenir de Pierre Notting, &c. 2nd, Messrs. D. PRIOR & SON, Colchester, whose best bloom was Maman Cochet; and 3rd, Mr. GEO. PRINCE, Longworth. Teas and Noisettes are very small in size generally this season.

Twelve Blooms distinct.—Mr. HENRY DREW, Longworth, Berks, won the 1st prize for twelve blooms, and generally they were very pretty specimens. The varieties were Maman Cochet, White Maman Cochet, Mrs. Ed. Mawley, Niphotos, Madame de Watteville, Souvenir d'Un Ami, Medea, Muriel Grahame, Madame Vermorel, Madame Hoste, and Madame Cusin. 2nd, Messrs. G. & W. H. BUCH, Peterborough. 3rd, Mr. JNO. MATTOCK.

ROSES IN VASES.

Some of the exhibits in vases were uncommonly attractive, a group of hybrid Teas being the best. The 1st prize for twelve varieties of Roses, five blooms of each, was won by Messrs. BENJ. R. CANT & SONS, 2nd, Mr. GEO. PRINCE; 3rd, Messrs. FRANK CANT & Co.

The collection of nine vases of hybrid Teas which gained the 1st prize for Messrs. A. DICKSON & SONS was very fine, consisting as it did of good flowers, and vigorous foliage of the varieties Marquise Litta, Mrs. David McKee, the beautiful Killarney, Dean Hole, Mildred Grant, Lady Ashtown, Chas. Grahame, Florence Pemberton, and Mrs. W. J. Grant. 2nd, Messrs. F. CANT & Co.; and 3rd Messrs. JNO. JEFFERIES & Co., Cirencester.

GARDEN OR DECORATIVE ROSES.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, had the best collection of garden Roses arranged on a space of 16 feet by 6 feet; Mr. JNO. MATTOCK being 2nd.

A class for a collection of single Roses was won by Messrs. FRANK CANT & Co. Rosa moschata alba, R. himalaica, Irish Brightness (crimson), R. rugosa alba, Irish Beauty (white), were some of the prettiest shown; but the intense heat of the afternoon caused these flowers to droop very much.

Messrs. FRANK CANT & Co. won 1st prize for bunches of twelve varieties of buttonhole Roses. This was a very good collection, but was remarkable for not containing the well-known "buttonhole" variety W. A. Richardson. We will give the names. They were as follows:—Gustave Regis, Liberty, Peace (pale yellow), Madame Jean Dupuy, Sulphurea, Maria Christina, Perle d'Or, Papa Gontier, Alberic Barbier, Lady Roberts, Ma Capucine, and Souvenir de T. Levet. 2nd, Mr. Jno. MATTOCK; and 3rd, Mr. Geo. PRINCE.

Other classes for nurserymen included one for a single vase of Roses, won by Messrs. JNO. JEFFERIES & SON; a basket of Roses, won by Mr. JNO. MATTOCK; and a dinner-table decoration of cut Roses, won by Miss MATTOCK, who employed a single Rose, white with faint blush, probably of the variety Una.

AMATEURS.

A similar number of classes was reserved for amateurs. The class for thirty-six blooms, distinct, was won by that indefatigable exhibitor the Rev. J. H. PEMBERTON, Havering-atte-Bower, Essex; Mr. CONWAY JONES being 2nd. The best eighteen blooms, distinct, were shown by Mr. M. BURDFIELD, Denne Park Gardens, Horsham. The same number of Teas and Noisettes were best from A. HILL GRAY, Esq., Newbridge, Bath; and the winning collection of twelve Teas and Noisettes was shown by Mr. W. MEASE, gr. to A. TATE, Esq., Downside, Leatherhead. Mr. MEASE had also the 1st prize for garden or decorative Roses. There were other classes, most of which were reserved for growers of a certain number of plants only.

NON-COMPETITIVE EXHIBITS

were numerous, the highest awards to these being two Gold Medals, which were obtained by Messrs. W. PAUL & SON, Waltham Cross, who showed a collection of Roses; and by Messrs. GEO. BUNYARD & Co., Maidstone, who had Roses, flowers of hardy herbaceous plants, Strawberries, &c.

Other firms exhibiting were Messrs. J. Peed & Sons, West Norwood (Silver Medal); Messrs. Jackman & Sons, Woking (Silver-gilt Medal); H. Cannell & Sons, Swanley (Silver-gilt Medal); J. Cheal & Sons, Crawley (Silver Medal); G. Reuthe, Keston (Silver Medal); H. J. Jones, Lewisham (Silver Medal); J. Laing & Sons, Forest Hill (Silver-gilt Medal); M. Prichard, Christchurch (Silver-gilt Medal); T. S. Ware, Ltd., Feltham (Silver-gilt Medal); Williams, Ealing (Silver Medal); and Mr. David Russell, Brentwood (Silver Medal).

GARDENERS' DEBATING SOCIETIES.

BRIXTON, STREATHAM, AND CLAPHAM HORTICULTURAL.—The above Society held its annual outing on Thursday, July 6, visiting, through the kindness of Mr. Leopold de Rothschild, the gardens and grounds at Gunnersbury House. The outing was in every way a success. The new annual garden was of great interest, and the rough flagstones for pathways with dwarf plants growing between were a novelty. Tropaeolum "Ball of Fire," and Salvia splendens growing in boxes on the roof of the house, presented a gorgeous effect viewed from the lawn. The beds of Roses, the Japanese garden, the unique collection of Water-Lilies, the imitation old wall, were all of interest. In the Bamboo-garden Arundinaria nitida was specially noted for the perfect condition of its foliage. The visitors were much impressed with their cordial and hospitable reception, and they will long cherish pleasant memories of the afternoon spent at Gunnersbury. J. M. B.

"**FLORULA MORTOLENSIS.**"—This is a catalogue of plants growing wild in the neighbourhood of La Mortola, and has been prepared by Mr. ALWIN BERGER. It has been drawn up by order of Sir THOMAS HANBURY for the benefit of the numerous visitors who come to see his gardens, many of whom are often not less interested in the indigenous than in the luxuriant tropical and subtropical plants under cultivation. The vegetation of this portion of the Italian Riviera in the immediate neighbourhood of Mentone is both rich and varied, as this useful catalogue abundantly testifies. Its luxuriance is due to the "great variety of locality that exists. There are dry, steep rocks, deep and fertile soil, bare sunny banks, shady and woody places, water-channels, the bed of a torrent, and the sea shore. The sub-soil is almost entirely limestone, in many places rich in fossils. Sand occurs only in one isolated spot close to the garden entrance, but it contains chalk as well, and does not influence in any way the wild vegetation." We should add that Mr. BERGER calls attention to the following volume as containing good illustrations of the Riviera plants:—*Contributions to the Flora of Mentone, and to a Winter Flora of the Riviera, &c.*, by J. TRAHERNE MCGGRIDGE (1871), and *Flowering Plants and Ferns of the Riviera, &c.*, by C. Bicknell (1885).

MARKETS.

COVENT GARDEN, July 12.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

REMARKS.—Strawberries are still arriving in considerable quantities, but owing to the wet weather they come in a soft condition. There are but few English Apricots obtainable in the market, although French and Spanish fruits are plentiful; those from the Continent arrive in boxes and in half-sieve baskets. Supplies of ripe Gooseberries are limited; those seen are of good quality, and mostly the variety Golden Drop. Large quantities of Tomatoes are arriving, some from the Canary Islands, but the majority are Channel Island produce. Home-grown Tomatoes are now appearing plentifully in the market. Peaches and Nectarines are very abundant. Trade on the whole is good.

COVENT GARDEN FLOWER MARKET.

THERE is a considerable falling off in supplies, and even those growers who do send find a difficulty in selling their produce. Some few things are still in demand, but trade generally is very dull. Small plants of Rose Dorothy Perkins in 48's and 32's are very pretty. Crimson Ramblers are also good. Growers with a local trade are now sending their surplus produce to market. Crotons, Dracaenas, Pandanus, and other foliage plants are to be had in well-coloured specimens. Show Pelargoniums are still plentiful, and zonals are still of good quality, as are also Ivy-leaved varieties; but although the best of these sell readily, there is no demand for plants of second quality. Bouvardias are already seen, but they are not wanted. Supplies of Verbenas hold out; they are still very good. Campanula Mayi is marketed by several growers. Marguerites are plentiful; the yellow varieties do not find such a ready sale as formerly. The variety Queen Alexandra is very good. Eulalia japonica variegata is not often seen in such good quality as now. Fuchsias are still very good. Among Lilliums there are Harrisii, longiflorum, lancifolium album and rubrum, also auratum. Good Mignonette may still be had, but if the hot weather continues supplies will soon be over. Some good Ericas are noticed, but there are many of these plants that are not well flowered. Tuberous-rooting Begonias may be had in good plants both in 48's and 60's. The Kalosanthes (Crassulas) are still plentiful. Ferns and Palms do not

command much attention, and to find purchasers they must be offered at low prices.

CUT FLOWERS.

Supplies are not quite so abundant, although still equal to all demands. Roses seem to sell for fairly good prices, while the best quality Carnations do sell well, but the small blooms and second quality Malmesons do not find purchasers at any prices. Flowers of Azalea mollis from retarded plants are seen, but meet with no demand. Lilies in all varieties especially *L. candidum*, are plentiful and cheap. Poppies of various sorts are showy, but it is only the best Iceland varieties that sell well. Among other hardy flowers those of *Alströmarias* are very pretty. The Shasta Daisies arrive in large quantities. *Gypsophila paniculata* is now obtainable; this species will displace *G. elegans*, which is still plentiful. Chinese Asters are already coming into the market, but the blooms are somewhat small. *Coreopsis grandiflora* is a favourite flower, and *Centaurea suaveolens* (Sweet Sultan) sells well. *Eucharis*, *Stephanotis*, *Tuberose*, and other flowers with short stems find few purchasers. Large supplies of hardy Fern-fronds and hardy foliage of various sorts, including Oak with bronze-tinted tips, are to be had; also Maidenhair Fern, *Smilax*, *Asparagus*, &c. *A. H.*, Covent Garden, Wednesday, July 12.

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Vegetables: Potatoes, 3s. 3d. to 8s. 6d. per cwt.; new, 1s. 9d. to 2s. per 21 lb.; Turnips, 6d. to 8d. per dozen bunches; Carrots, 6d. to 8d. do.; Cucumbers, 1s. 9d. to 3s. per dozen; Onions, foreign, 2s. 6d. to 4s. per bag; Parsley, 4d. to 6d. per dozen bunches; Lettuces, 4d. to 6d. per dozen; Cauliflowers, 1s. 3d. to 2s. 6d. do.; Cabbages, 4d. to 7d. do.; Peas, 4s. to 6s. 6d. per hamper; Beans, 4s. do.—Fruit: Oranges, Valencia, 10s. to 21s. per case; Lemons, Palermo, 9s. 6d. to 20s. do.; Apples, Lisbon, 9s. 3d. to 11s. 6d. do.; Tomatoes, 8s. 6d. to 12s. do.; Melons, Valencia, 36s. 10s. do.; Bananas, 4s. to 8s. per crate.

EDINBURGH.—Oranges, Valencia, 15s. per case; Grapes, English, 1s. 9d. to 2s. per lb.; do. Belgian, 1s. 4d. do.; Lemons, Palermo, 10s. to 18s. 6d. per case; Apples, Australian, 13s. 6d. to 15s. 6d. per case; do. Lisbon, 15s. do.; Bananas, 5s. 6d. to 10s. per bunch; Nuts, Barcelona, 35s. to 38s. 6d. per bag; Nuts, 18s. 6d. to 20s. per cwt.; Figs, 9s. per dozen; Walnuts, Italian, 6s. 6d. per cwt. Vegetables: Tomatoes, Guernsey, 53d. to 6d. per lb.; Onions, Egyptian, 4s. per cwt.; do. Valencia, 7s. 6d. to 8s. do.; Carrots, 1s. per dozen; Potatoes, Canary, 8s. to 8s. 6d. per cwt.; do. Maltese, 7s. 6d. do.

DUBLIN.—Vegetables: Potatoes, new, sandy, 4s. 6d. to 5s. per cwt.; clays, 5s. to 5s. 6d. do.; Cabbages, York, 5s. to 9s. 6d. per load; Cauliflowers, 2s. to 2s. 6d. per basket; Parsley, 2s. per bag; Parsnips, 2s. 3d. to 2s. 6d. per cwt.; Carrots, 10d. to 1s. per dozen; Onions, Tripoli, 4d. to 5d. per bunch; Turnips, white, 13d. to 2d., do.; Rhubarb, 11d. to 1s. per bag; Salad, 6d. to 11d. per dozen; Peas, 4s. to 4s. 6d. per bag.

ENQUIRY.

GERMINATION OF SEEDS.—Can any of your readers give me an idea as to how long the following seeds take to germinate, if good?—*Clivia nobilis*, sown May 20, in temp. 85° (approx.); *Agapanthus*, *Amaryllis*, *Begonia Rex*, *Phoenix dactylifera*, *Latania borbonica*, all sown on May 26 in a cool-house: *Arum*, *Camellia*, *Ardisia crenulata*, *Hydrangea grandiflora*, *Nephrolepis exaltata*, *Aloe* (Waggon Hill), and *Cactus*, all of which have been sown in a cool-house. *T. R. P.*

TRADE NOTE.

MR. H. ELLIOTT, of Courtbushes Nurseries, Hurstpierpoint, has taken over the glass portion of the Hassocks Nurseries, Hassocks, Sussex, so long carried on by Messrs. W. Balchin & Son, where he intends largely to extend the culture of Tree- and Souvenir de la Malmesons Carnations.

GARDENING APPOINTMENTS.

MR. C. CORKE, for some time employed by Messrs. JOHN PEED & SON at their Breamham Nurseries, as gardener to Mrs. ARNOLD, Burton Joyce, Sidcup, Kent. Mr. ROBERT WEEKS, for the past four years Foreman at Cuffhells, Lyndhurst, as Gardener to J. M. YOUNG, Esq., Oak Bank, Hamilton, Ontario, Canada. Mr. J. K. HOARE, for the past five years General Foreman in The Gardens Iwerne Minster House, as Gardener to JAMES HAWKE DENNIS, Esq., Grebehurst Park, Surrey.

CATALOGUES RECEIVED.

BROWN, THOMPSON & CO., 86, Patrick Street, Cork—Flower & Vegetable Seeds.

MR. ECKFORD.—We are glad to learn that the Council of the Royal Horticultural Society has selected this well-known raiser of Sweet Peas to receive the Victoria Medal of Honour in Horticulture.

"INDEX KEWENSIS."—The Oxford University Press announces that the second part of the second supplement to the *Index Kewensis* will be ready immediately. This supplement covers the period 1896 to 1900. In the original work the genera and species of flowering plants from the time of LINNÆUS to 1885 were enumerated; and the first supplement carried on the list to 1895.

ANSWERS TO CORRESPONDENTS.

* Owing to pressure of matter we are compelled to hold over a Report of the Wolverhampton Show until our next issue.

BEGONIA: *T. G.* Sufficient Tobacco-juice to discolour the water will be sufficient. Dip the plants occasionally in a weak mixture rather than incur a risk of injuring them by the use of a stronger liquid.—*W. H.* Your leaves are affected with the mite. Dip the leaves in tobacco-water.

CUCUMBER LEAVES: *G. B.* Your leaves have one of the forms of "spot" which is so destructive. The shortest way is to destroy the whole crop, turn out the soil, whitewash the walls, mixing a little sulphur with the whitewash, and start afresh.

CUCUMBER: *G. B. M. R.* The plants are affected with a slime-fungus, of which we will endeavour to give you the name in next week's issue. Try an application of powdered sulphur to the healthy plants as a preventive.

EARWIGS: *Hemploe.* Continue with the solution of soft-soap and paraffin, keeping it mixed well during its application. Be careful not to use too strong a mixture.

FLOWER-DISPLAYERS: *C. M.* They can be obtained from Mr. J. Williams, Oxford Road, Ealing.

FUNGUS ON HEDGE: *J. W.* The fungus on your hedge is what is generally called *Roestelia laecrata*, but which is a form of a very different-looking fungus growing on Junipers. Cut the affected branches off and burn them, and if there are any Junipers in the neighbourhood destroy them also.

LILIUM AURATUM BULBS: *J. P.* Your bulbs are attacked by bulb-mites and other insects. Fungus probably comes to aid in the destruction.

MELON: *Constant Reader.* We cannot find any insect, but the appearances suggest injury from a mite or other biting insect, which has killed the skin. We do not think it is scald from syringing.

NAMES OF FRUITS: *In forwarding Peach or other soft fruits to be named, it is imperative that two specimens of each variety be sent, also a shoot with foliage, as identification is sometimes established by the character of the glands. The fruits should be gathered just before they are quite ripe. Wrap each fruit in tissue-paper, and pack them very carefully in soft material and in a wooden box that will not be likely to get crushed in the post. Pack sufficiently tightly to prevent the fruits from shaking in the box. In the case of Peaches it should be stated whether the tree produces large or small flowers. Do not post at the week-end, when delay may be reasonably expected.*—*E. Bambridge.* Peach Sulhamsted.—*H. F.* Grape West St. Peter's.

NAMES OF PLANTS: *J. S.* *Listera ovata*, the Twayblade.—*G. H.*, Yorks. *Oncidium Harrisonianum*, of the Pulvinata section, so far as we can judge by the small specimen sent. There is little room for doubt, as the cushion-like crest is peculiar to this small section.—*J. J.* A variety of the Japanese Iris, *I. Kämpferi*.—*W. F. B.* A viviparous form of grass, probably *Poa alpina*—*Bids*. Probably *Broughtonia sanguinea*, but it is difficult to be quite certain from the pressed flowers. Can you send us a rough sketch of the plant as growing?—*R. E.* 1, *Catananche cœrulea*; 2, *Veronica salicifolia*; 3, *Agrostemma coronaria*; 4, *Mimulus glutinosus*; 5, *Lysimachia vulgaris*; 6, *Linaria reticulata*.—*G. L. M. R.* 1, *Veronica longifolia*; 2, *V. longifolia* var. *subsessilis*; 3, *Lonicera*; 4 and 5, varieties of *Artemisia abrotanifolia*.—*G. H.* 1, *Agrostemma coronaria*; 2, *Galega officinalis*; 3, *Codium elegan-*

tissimum; 4, *Epilobium angustifolium*; 5, *Thalictrum majus*; 6, *Erigeron* sp.—*W. J. D.* *Tragopogon pratense*.—*A. T.* See last week's issue; 5, *Adiantum Capillus-Veneris*; 7, *Pteris cretica*; 8, *Adiantum excisum multifidum*.—*T. G.* *Linaria hepaticifolia*.—*B. L.* A Maple, probably *Acer dasycarpum*.

OAKS: *J. C.* Both leaves sent appear to be *Quercus rubra*, but foliage alone is insufficient to enable us to determine the species with certainty. The best Oak for affording colour in autumn is *Quercus coccinea* var. *splendens*; but all the forms of *Q. coccinea* are good. A form known as *Q. Greyana* colours well; *Q. palustris* colours well in some positions; *Q. rubra* is variable in this respect. See an article in our issue for April 1, 1905, p. 194.

ORPHAN FUND: *W. M.* We are more than surprised that any reader of this Journal should be ignorant of the names of the Executive of this excellent Charity. The Secretary is Mr. Brian Wynne, 30, Wellington Street, Strand, London, W.C., and donations can be sent to him, or to any of the members of the Committee.

PEACH WITH ILL-FORMED STONE: *C. B.* It is quite clear that the injury is not in the first instance due either to fungi or insects. The cause is due to some cultural defect that can only be ascertained on the spot. We advise you to keep plenty of lime in the soil; take care that the drainage of the border is efficient, and that the roots are not allowed to suffer from drought or from excessive wet.

PEACHES: *R. H. C.* The cracking is due to unequal growth, but what caused that irregularity we cannot tell.

PEAS: *W. D.* The pods are affected with thrip. Try spraying the Peas with an infusion of Quassia—a handful of Quassia-chips in a gallon of boiling water, and allowed to cool before use.

PINK: *Hemploe.* It is quite likely that the circumstances were as described by your friends. We have known the variety Mrs. Sinkins to behave in a similar manner, and occasionally to revert to the single form.

PURCHASE OF BULBS: *F. B.* We cannot advise you in this matter. Consult a solicitor.

ROSES: *A. J. F.* Some boring insect. You can do nothing but burn the affected shoots. Watch the answers in this column for the next week or two.

SWEET PEA: *E. J. L.* The unusual number of flowers is due to fasciation or a fusion of two or more flower-spikes—an abnormality of not infrequent occurrence.

TOMATO: *G. B.* Your Tomatoes are affected with fungus—*Cladosporium fulvum*. Try spraying with Bordeaux-mixture. Be sure to burn the affected plants.

ZYGOPETALUMS: *W. J. N.* Your plants appear to be affected with what is known among Orchid growers as "spot," the cause of which has never been definitely settled, but which in many instances seems to be brought about by cultivation in the same house, and perhaps in one not quite suitable, for a number of years. Once affected the plants are liable to it even on the current year's growth, which up to a certain point seemed healthy. It would be best to get rid of these plants and procure fresh stock. But if you elect to keep them, cut away all the affected parts and give the plants a change for five or six weeks under a shady wall in the open garden.

COMMUNICATIONS RECEIVED.—Basil Levet (your communication has been forwarded)—*J. C. & Co.*—*T. E. H.*—*E. McF.* Sydney.—*James Veitch & Sons.*—*H. C. L.*—*H. R. H.*—*J. F. D.*—*J. S.*—*F. W. M.*—*W. S.* (photograph).—*Mrs. O.*—*F. D. D.*—*J. C. & Co.*—*J. R. P.* & *S.*—*J. O'B.*—*J. S.*—*F. J.*—*J. D.*—*A. D.*—*S. A.*—*Sir Chas. S.*—*Essex.*—*N. S.*—*F. G. B.*—*North-East-Amateur National Carnation and Picotee Society*—*Rufus*—*Constant Reader*—*Nectarine*—*W. R. Smith*—*Ajax*—*Swailey Horticultural College*—*C. C.*—*A Reader*—*E. C. C. D.*—*W. H. THE CARNATION.

THE National Carnation and Picotee Society (Southern Section) was to the fore in Vincent Square last Tuesday. It is just thirty years since the formation of the Society. I met the late Mr. E. S. Dodwell at a Carnation exhibition at Manchester in 1875, and it was evident that the Carnation, the Tulip, and the Auricula as florists' flowers were in the hands of enthusiastic cultivators there. Mr. Dodwell, who had cultivated the Carnation for twenty-five years previous to this, but had not grown a plant for twenty years, thought that something ought to be done in the South. A meeting was held during the following autumn. Very few of the members of the first committee remain to see the great work that has been accomplished. I well remember the beautiful Carnation and Picotee blooms that were exhibited at Manchester, but flowers were not admitted unless they were flakes and bizarres, or white-ground Picotees, no self colours or yellow-ground Picotees; none of what for exhibition purposes are termed "fancies." When the Southern growers began their work in earnest it was felt that something should be done outside the rather restricted groove in which the florists had hitherto been content to work. Prizes were offered for yellow-ground Picotees, and although the varieties exhibited were not of a high standard of merit, it was not long before there was improvement, not only in these yellow-ground varieties, but also in the flaked and bizarre

varieties. Soon afterwards prizes were offered for self-coloured flowers, and also for the so-called fancy varieties. If we may judge by the taste of the flower-loving public, the flakes, bizarres, and white-ground Picotees are not the most highly esteemed nowadays. The self-coloured varieties stand first, and for garden purposes deservedly so, as they grow so freely, and flower-beds can be formed of one colour—white, bluish, pink, rose, apricot, buff, amber, crimson, red, scarlet, and many shades of each colour.

Yellow-ground Picotees have now so much improved that they hold the second place in popular esteem. The class for "fancies" was introduced specially for all Carnations that might be produced from seed, but which could not be admitted into the other classes, although there are many very beautiful and remarkable flowers amongst them, as might have been seen at the exhibition which was held on Tuesday. There are of course many Carnation fanciers who do not care for any flower that is not in accordance with the old types, and I for one have intense admiration for the fine form, the rich and varied markings of the bizarre and flaked varieties, also for the pure white of the Picotee, with no spots or bars to dim its lustre, only the pretty margin, broad or narrow, of red, rose, scarlet or purple.

Many of the varieties now grown have been cultivated to such a high standard of excellence that they cannot be shown better, but by continuing to raise seedlings there is still a chance of obtaining improved varieties. Moreover, in the process of raising seedlings from flaked varieties and Picotees, many varieties are produced of rich self colours and exquisite form.

The results obtained from the seeds of the white-ground Picotee are very remarkable. In some of the varieties that have the merest line of colour on the edge of the petals, the seedlings will produce self-coloured flowers of this colour only, purple-rose, red or scarlet, and in the case of the bizarre and flaked varieties, many of quaint design and varied colours, which in the old days were thrown over the garden fence, are now treasured. In addition to the improvements to be expected from the raising of seedlings, there is the advantage that if the seed has been saved from choice varieties and cross-fertilised flowers, a more vigorous class of plants may be obtained. In the course of years old varieties become weaker in constitution, and must be replaced by others of more vigorous growth. The subject of deterioration in varieties was treated upon very fully in the *Gardeners' Chronicle* for March 25, 1905, p. 184, and need not be further enlarged upon now, except to state that its effects may be greatly modified by careful cultivation, and by the introduction of new varieties.

Many amateurs do not plant the seedling Carnations at the right time, and thus they fail to obtain satisfactory results. The young seedlings should be planted now, or at least not later than September, so that the plants may be well established before the winter, in good deep soil that has been enriched with some decayed farmyard manure. The best time to sow the seed is in March or April; if sown too early some of the plants will make an attempt to throw up flower-stems too late in the season properly to develop the blooms.

The single-flowered Carnation with its five petals produces seed very freely indeed, without any attempt on the part of the cultivator to pollinate the flowers. Not so the garden Carnation; the anthers which contain the pollen are hidden amongst the petals, and must be sought for. When the pollen is in a state of powder carefully remove it with a fine brush and apply it to the stigma of the flower it is intended to pollinate. This is found in the centre of the flowers, in the form of two horn-like processes more or less curled; the pollen is gently applied with the aforesaid brush. If the flower has been fertilised the petals will soon collapse.

The propagation of the Carnation is not so well understood as it ought to be. Layering is the next best method to that of seed-production, and the best time to do the work is when the flowering period is over; some of the surface soil is removed and replaced with the fine, sandy soil in which the layers are to be pegged down. A good compost to make these layers in is one consisting of one part sand, one part fine loam, and one part leaf-mould.

I am frequently asked if Carnations can be propagated by slips or cuttings. The process is not so certain a one as layering; for although many varieties can be freely propagated by slips others are more difficult to raise. So long ago as the time of Queen Elizabeth the Carnation was propagated by slips, and it is interesting to read in *The Winter's Tale* the conversation between "Polixenes" and "Perdita," that the "Carnations and streaked Gilliflowers" are mentioned. "Perdita" was no florist; she says, alluding to the "streaked Gilliflowers":—

"Of that kind
Our rustic garden's barren; and I care not
To get slips of them."

As companions of the Carnation they may have some claim to be admitted as "the fairest flowers of the season," and "Polixenes" remonstrates with her:—

"Wherefore, gentle maiden,
Do you neglect them?"

Her objection was that they were by some called "Nature's bastards" [and her further remarks show that the practice of cross-breeding was not unknown in those days]. She adds—

"I'll not put
The dibble in earth to set one slip of them."

Some of us can remember that the former editor of the *Gardeners' Chronicle* protested quite as strongly against the cross-fertilisation of Orchids. The point to which I would call attention is that in these early days Carnations were propagated by slips. Some varieties cannot easily be propagated by slips, although most of them can, and they root most freely in a very gentle bottom-heat in a frame or handlight.

The seedlings which have been raised during the present season, if planted early, will produce a hundred blooms less or more on each plant. These, if cut with long stems, flowers and buds together, accompanied with Carnation foliage, form the most charming of table decorations.

If there are any incipient examples of Carnation-rust to be seen, the affected parts must be carefully cut out and destroyed; for as the summer advances into autumn this tiresome pest will rapidly develop, and if the spores become scattered the labour of getting rid of the disease will be greatly increased. *J. Douglas.*

NEW OR NOTEWORTHY PLANTS.

PRIMULA OVALIFOLIA, Franchet.*

[SEE SUPPLEMENTARY ILLUSTRATION.]

THIS very handsome species was discovered in 1869 by David on the borders of E. Tibet, in the Province of Moupin. It has since been collected by A. Henry and Wilson in Hupeh and Szechuan and by Pratt near the Tibetan frontier in W. Szechuan. Its nearest ally is, according to Franchet, *P. Davidi*, another most lovely plant, found also by David in Moupin. It differs from the latter by its oval, crenate, and usually long-petioled leaves, and by its longer and narrower calyx-lobes. *J. F. Duthie, Kew.*

[Our illustration was taken from a living specimen furnished by Messrs. James Veitch & Sons, who have the plant in cultivation. En.]

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT MESSRS. SANDER AND SONS'.

CYPRIPEDIUM FAIRRIANUM has arrived at St. Albans at last. For many years Messrs. Sander have persistently striven to secure an importation of this gem among Cypripediums, and no fewer than six collectors were successively sent out for the purpose of procuring this plant as their chief object. At last a small consignment of healthy, compact tufts has been secured. About the identity of the coveted species there can be no doubt. The difference in the form and length of the leaves, and the superior length of the old flower-spikes on some of the imported plants, seem to indicate that there will be some variation in the flowers, although all are true Fairrianums. The leaves of some of the imported plants are broad and short, and resemble those previously in cultivation, although they are much larger, while the leaves of a few are nearly a foot long, and narrow in proportion to their length. Amateurs will rejoice at the opportunity to satisfy their cravings for this charming plant. The difficulty, however, is that there will not be enough to "go round," and it is said that no more can be imported until some better prospect of security for the collector is forthcoming.

Although the re-introduction of this small healthy batch of *C. Fairrianum* was not directly due to the agency of either of the travellers specially sent by Messrs. Sander, their labours were not altogether wasted, for through them many other good plants were introduced, and among the more recent importations now at St. Albans are the stock of the handsome *Cymbidium Sanderi*, the few specimens of the showy *C. Parishii Sanderæ*, and various other promising species not yet proved.

* *Primula ovalifolia*, Franchet. — Root-stock short, stout, giving off many fibrous roots. Leaves all radical, subcoriaceous, more or less bullate; blade $2\frac{1}{2}$ –4 inches long, and $1\frac{1}{2}$ –2 inches wide, broadly ovate to obovate-lanceolate, rounded at the apex, abruptly or gradually tapering into the petiole; margins crenate; midrib stout; main lateral nerves 10–12 pairs, often spreading at a right angle to the midrib, the interspaces sharply reticulate; upper surface glabrous, the lower paler, densely puberulous along the nerves and midrib, the latter clothed also with reddish, spreading hairs; petiole varying in length, often longer than the blade, covered with reddish, woolly pubescence, like that of the midrib. Scape usually exceeding the leaves, its upper portion as well as the pedicels woolly-pubescent. Bracts lanceolate, acuminate, about as long as the pedicels at the time of flowering, reddish-brown, the margins ciliate. Pedicels (in flower) shorter than the calyx. Calyx 5–6 in. long, campanulate; lower portion of tube pubescent; lobes about as long as the tube, lanceolate-acuminate or triangular, the margins ciliate. Corolla violet-purple, about $\frac{1}{2}$ inch across, tube equalling or (in the short-styled form) exceeding the calyx; limb concave, spreading; lobes obovate, shortly two-lobed. [See Franchet in *Bull. Bot. Soc. France*, xxxiii., p. 67; *Pax. in Engler Jahrb.*, x., 176; ex Hemsley in *Journ. Linn. Soc.*, xxvii. (1859), p. 41.]

Hybrid Orchids take up a great proportion of this vast establishment, and house after house is filled with seemingly endless quantities of them. A range of warm-houses running side by side is devoted to the raising of seedlings, and their growth in the earlier stages, and with regard to the seed-raising, Mr. J. Godseff, the talented manager, states that the crosses which were found difficult to raise when the house was newly constructed come very freely and with greater vigour now that the house has lost its newness. Cypripediums occupy many houses, one house having a large quantity of yellow forms of *C. insigne*, the best of which much resembles a yellow *C. i.* Harefield Hall; another house has batches of *C. bellatulum*, *C. niveum*, *C. Godefroyæ*, *C. concolor*, and their hybrids, and with them the new yellow *C. Sanderæ*, of the *C. concolor* class, but larger and with a broad and differently shaped lip.

The next house has Cypripedium Sanderianum and its hybrids, and *C. Rothschildianum* and its hybrids. Indiscriminate crossing has been abandoned here long ago, and only crosses of the best forms effected. Of these there are in different stages of growth enormous quantities.

The present season is one of the least varied perhaps in the matter of Orchids in bloom, but even now there is a very fine show of *Lælio-Cattleyas* in three houses. The showiest batch in bloom is *Lælio-Cattleya* × *Martineti*, obtained between a fine dark form of *L. tenebrosa* and a richly-coloured *C. Mossiæ*. The plants of this batch vary in an extraordinary manner, some being white tinged with rose and with purple labellums, others of various shades of rose and purple, this class showing little trace of *L. tenebrosa*; the other set has the bronzy-orange sepals and petals of *L. tenebrosa*, though broad and flat, and intensely dark claret-purple labellums. The same variation shows in the fine strain of *L.-C.* × *Canhamiana* and the newer *Cattleya* × *Roehrsiana*, one being pure white with dark purple lip, the other having the crimped petals tinted with lilac. Batches of *Lælio-Cattleya* × *bletchleyensis*, *L.-C.* × *Aphrodite* and other showy hybrids are in bloom or bud, and most of the other favourites are showing well for flower.

The arrangement of rockery-approaches, with similar constructions in the ends of the houses on which to arrange plants in flower, and the facing of the staging with ornamental plants always form an attractive feature in the St. Albans nurseries. In one of these groups at the ends of the houses stands the finest specimen of *Vanda Lowii* ever grown. It now has over a dozen leading growths, and is still producing more. Around it are *Vanda Kimballiana*, *Renanthera Imschootiana* with pretty crimson flowers, *Aërides expansum Leonis*, *A. crassifolium*, and another fine *Aërides* from Annam; also a distinct type of the true *Vanda Parishii*, and some other species.

At the entrance of another house is a noble specimen of *Brassia verrucosa major* with thirty spikes, some fine *Odontoglossum crispum*, a large specimen of *Nanodes Medusæ* with its singular ruby-red flowers, and other fine species being grouped with it.

The cool-houses, filled for the greater part with fine *Odontoglossum crispum*, have but few in flower, as usual at this season. Among those noted were a remarkably fine *O. ramosissimum*, the singular little *O. stellatum*, and a few hybrids. The collection of *Masdevallias* had several examples of *M. muscosa*, *M. trichæte*, *M. calura*, and other species usually called "botanical," in bloom; and with regard to these singular species the collection is being increased at St. Albans, and quite an interesting show of *Bulbophyllums*, *Cirrhopetalums*, curious *Epidendrum*s, *Cœlogynes*, *Dendrobiums*, &c., chiefly of recent importation, is being established. Among those in bloom were the pretty *Dendrobium bellatulum*, a dwarf

form of *D. ciliatum*, *Sarcochilus divitiflorus*, *Pachystoma Thompsonianum*, *Chondrorhyncha Chestertoni*, and several small species of *Epidendrum*, *Polystachya*, and *Pleurothallis*. The large range, nearly 300 feet in length, and in five divisions, completely filled with hybrid *Lælias*, *Cattleyas*, and *Lælio-Cattleyas* of flowering size, present a fine sight of vigorous plants. Few are in bloom, but a great number are showing for flower.

The next intermediate range has *Cattleyas* and other Orchids, the great bulk of which, however, are grown at Bruges. Among those remarked were a recent importation of *Cattleya elongata*, a fine lot of *Cattleya Schröderæ*, *C. Mendeli*, and other large-flowered kinds. In bloom were several *Lælia majalis*, a finely-coloured *Cattleya Loddigesii*, the pure white *C. intermedia Parthenia*, and a large form of the white *C. Mossiæ Wageneri*, *Oncidium lamelligerum*, *Epidendrum prismatocarpum*, a large specimen of *Oncidium phymatocœlum* with many elegant flower-spikes, and one of the noblest and most vigorous specimens of *Vanda cerulea* ever seen, with some fifty broad, fleshy leaves on a single stem, and three fine spikes of sky-blue flowers of fine size, each with about fifteen blooms.

The range connecting another large block of warm-houses is filled with Burmese *Dendrobies*, *D. Wardianum*, *D. crassinode*, *D. Brymerianum*, *D. Bensonæ*, &c., among the last-named two white varieties being in bloom.

In one of the side houses a good variety of *Pescatorea Klabochozum* is in bloom intended for crossing with another section of *Zygopetalum*; also *Calanthe veratrifolia*, a nice batch of which has been imported, various *Spathoglottis*, *Cœlogynes*, a sturdy lot of *Vanda Sanderiana*, which promise a good show of flowers; the true *Vanda insignis*, still a rare plant; a fine batch of *Stenoglottis longifolia*, with tall sprays of pretty lilac-and-white flowers; a good lot of *Phalæopsis*, several of the *P. grandiflora* being very large specimens.

NEW AND RARE PLANTS OTHER THAN ORCHIDS.

Nicotiana Sandera × has been one of the most satisfactory plants both to the vendors and purchasers, and endeavours are being made to preserve the brightest crimson, magenta, rose, and white types true, and to still further improve the strain. It is noteworthy that the flowers of this plant keep open and bright in dull and sunny weather alike, while *Nicotiana affinis* and others close the segments of the flowers, giving them a drooping appearance, according to the weather.

The foliage *Begonias* raised at St. Albans out of the handsome *B. Bowringiana* have also developed a new and extremely beautiful race, with wonderfully coloured leaves, the midribs having a glowing cinnabar scarlet appearance. A fine set are *B. Mrs. H. G. Moon*, *B. Her Majesty*, *B. Fearnley Sander*, *B. Non Plus Ultra*, and *B. Our Queen*. These are bright and charmingly coloured, whether used planted out in the rockeries, or arrangements planted in the Orchid-houses, as well as when grown in pots.

Gloriosa Rothschildiana, the most beautiful of the genus, is established in a good batch which by the variation in the foliage promises some variety in this always beautiful flower.

Cycas Micholitzii is a remarkable species of elegant habit, and showing the new character in a Cycad of having the lower leaflets pinnate; *Alpinia Sandera* has Bamboo-like growth, the leaves variegated white and green. It is said to be a fine plant for indoor decoration. *Anthuriums* are much grown of two sections, viz., the *Schertzerianum* and the *Andreanum* classes. Both are very showy and varied, but the newer forms of the *Andreanum* class, now least in

evidence, are said to bloom well in autumn and winter.

Polypodium Knightia is an ideal basket plant with long, drooping, feather-like fronds much divided. Many other freshly-imported promising plants are being established, and of older favourites *Dracena Sanderiana*, *D. Godseffiana*, and *Asparagus myriocladus* are as well worthy of their place as decorative plants as ever.

It is interesting to note that while the vast establishment at Bruges, with its many houses of

CYMBIDIUM HUTTONI.

Owing to the courtesy of Messrs. Charlesworth & Co. we are now able to illustrate in figs. 21 and 22 this remarkable and beautiful species, for which the firm obtained a First-class Certificate at a meeting of the Royal Horticultural Society on July 4. As was stated in our report of that meeting, the species was originally discovered by Hutton when collecting for Messrs. Veitch in Java. The species connects *Cymbidium* and

halves. The sepals are obovate, acuminate, petals narrower and reflexed. The side-lobes of the lip are large and erect, middle lobe oblong, acuminate.

FORESTRY.

SOME NOTES AT PARK ROYAL.

GENERALLY speaking, the exhibition alluded to on p. 18 did not differ very much from that of last year, the exhibits in most cases being the same, the most interesting coming from private estates. One of these, from the Duke of Northumberland's woods, Alnwick Castle, was instructive, only it was missed by many visitors owing to its position. This consisted of two Scotch Fir stems, about twenty years old perhaps, of the dimensions of short pit props, "showing the effects of thick planting in producing crops and good quality of

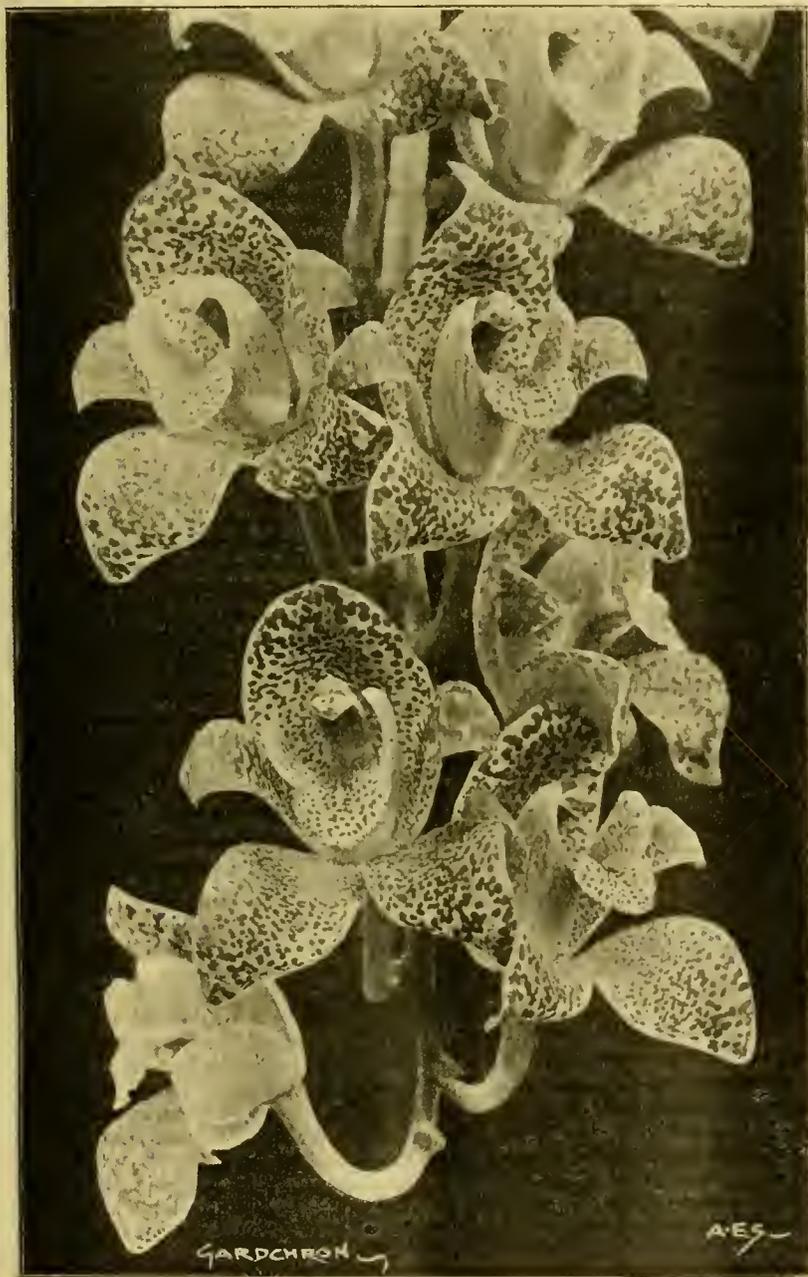

FIG. 21.—CYMBIDIUM HUTTONI: FLOWERS NATURAL SIZE, YELLOW WITH PURPLE SPOTS.

FIG. 22.—CYMBIDIUM HUTTONI, SHOWING HABIT OF PLANT.

timber." Both examples were about the same girth, but the wide-planted one, owing to having had too much room, had the objectionable strong, rigid, side branches and was tapering, and the boards from trees grown on the same principle were full of large knots and rough. The dense-planting example was about as thick at the small end as at the bottom, cylindrical, and the side branches were small and dead approaching the shedding stage. Boards of the same showed few knots, and they were small. The rough and inferior specimen came from a plantation planted at the rate of 2,722 to the acre, and the good specimen represented 4,840 to the acre. Considering, therefore, that the latter was of superior quality in every way, and that the trees were of the same age, the reader may draw his own conclusions as to the value of the crop per acre in each case at their age.

From Earl Powis's estate came a section of Douglas Fir, forty years of age, varnished, showing the colour and annual rings, and indi-

Palms, Orchids, &c., and outdoor acres of Bay trees and Azaleas, steadily becomes a wholesale-market-supplying nursery, the parent establishment at St. Albans still caters for plant-lovers of all kinds, and especially for those who appreciate new things. J. O'B.

PLANT PORTRAIT.

DEBREGEASIA VELUTINA.—A tree of the Nat. Ord. Urticaceae. Native of India. Leaves shortly stalked, rugose, lanceolate, serrate. Fruits yellow in small globular heads.

Grammatophyllum, the large grooved pseudo-bulbs, each furnished with two or three bright-green leaves, much resembling those of *Grammatophyllum multiflorum*.

The manner of producing the pendulous racemes of thick-textured flowers is nearest to that seen in *Cymbidium Devonianum*. Two varieties were shown, one lighter in colour than the other, the longest raceme bearing fifteen flowers. The flowers were each about 2 inches across, in colour yellowish-white densely spotted with purple, the petals being also tinged with purple on the outer

ating a stem about 24 inches in diameter; and beside this was a Larch section, about 100 years old, as shown by the rings, of no greater bulk than the Douglas. I laid the one on the other to measure, and judging approximately, but pretty nearly, I calculated that the conditions being about equal, the Douglas Fir will produce about as much timber in forty years as the Larch will do in a hundred. The heart of the Douglas was as red as Mahogany, and constituted about two-thirds of the section, which exceeds that of any other of our forest trees. The early formation of heart-wood is of much importance in the value of timber.

Another exhibit which attracted much attention among planters was a neatly-assorted collection from the Country Gentleman's Association of seeds of about forty varieties of our principal forest trees, with pots of newly-sprung live seedlings representing the different seeds. This, I believe, is the first exhibition of the kind, and interested many who perhaps never saw some of the seeds exhibited before, nor the seedlings either. Should the C.G.A. exhibit the same again, I would suggest that instead of sprouting seeds for the occasion, it would be better to procure one, two, and three years' seedlings and pot them for the purpose. This would be easier and better. If the Association on the next occasion could also set up a clump of small scaffold-poles near their pavilion, showing how thickly the actual crop of trees are where they grow, it would give us the beginning and end of the business. This was suggested at the time of the Forestry Exhibition in Edinburgh in 1884, but the idea was not acted upon.

The plots in the forestry section, correctly described in the catalogue as "Collections of choice hardy ornamental trees and shrubs," were such as one sees at flower-shows, but could not be regarded as forestry exhibits. There was one solitary Japanese Larch, representing forestry; all the others were garden and park subjects. The useful Firs and hardwoods were not there. Perhaps it would be difficult, but more real, living forestry is wanted at these forestry exhibitions. There is too much of the museum about them. In the agricultural division attached to the forestry section, living plants, consisting of cereals, grasses, roots, &c., and showing cultural results and experiments, were more interesting, and attracted the notice of the visitors.

Samples of creosoted trunks in variety were exhibited, showing creosoting by pressure and absorption. The latter is the slowest process, but much the easier and least expensive. In other respects this exhibit had little interest, timber-creosoting having been long understood and practised in railway material. The question now is whether it is cheaper to buy creosoted timber or to creosote one's own when there is much timber on the estate. By the absorption process the wood is simply put into the boiler and allowed to soak, a slow fire being lit under the boiler. By the pressure system a good deal of the engine-tenters' duties are involved, and the plant is more expensive at the outset.

Instructive exhibits from one of the Forestry Schools, Cambridge, if I remember, were examples of young trees showing the right and wrong root-form in young forest trees, and some frightful examples of the latter were exhibited of various ages, showing how the wrong form, once established, is retained by the tree. This exhibit has only come to the fore within the last few years since attention was drawn to it. All the examples were described as from English nurseries except one or two from a German nursery, probably one which supplies English planters, as in the Continental forests the wrong root form is practically unknown.

An interesting exhibit to forestry students was that showing the damage done to

forest trees by diseases, insects, voles, and squirrels. The two last were perhaps the only ones that excited much interest among practical foresters because they can be dealt with. Forest tree diseases and insects are a heavy feature at agricultural schools, but most of them are either so little feared in practical forestry or so hopelessly beyond the forester's control when they do appear, as in the Larch disease and Larch aphid for example, that the forester troubles little about them. I think Dr. Somerville told one of the examiners of the late Forestry Committee that the insects to be feared in forestry were about half-a-dozen or fewer, and were out of the reach of preventive measures. If the forester could get rid of the rabbit pest and the Larch disease, it is doubtful if he would trouble his head very much about any of the other plagues. These two undoubtedly do far more harm than the insects, diseases and plagues put together. An extraordinary exhibit, according to the catalogue description, was a door, from Ryston Hall, Norfolk, made of Black Oak dug out of Roxham Fen, and supposed to be "70,000 years old." Some wondered if this was a misprint for 7,000. *J. Simpson.*

THE TIMBER VALUE OF EXOTIC TREES.

I have had twenty-six years' experience here with several members of the Pine family, as well as with Larch, in all to the extent of 500,000 trees, and I have come to the conclusion that in our case it has been to some extent a waste of time and capital.

Every person who contemplates planting trees in large numbers should study well the conditions of the locality, his requirements, and whether he is planting for obtaining immediate profit, or for the benefit of his heirs. If he wishes for immediate profit, then extra caution is needed in selecting the varieties.

The Larch is the most serviceable tree to plant for the purpose of yielding timber for use on the estate in fencing and so on. At one time it paid to plant Larch for producing Hop poles at twelve to fifteen years' planting, but now that wire is so much employed, Larch under eighteen or twenty years from planting is of no value.

The point then to consider is of what value are the small poles that must be taken away as thinnings? By leaving them too thickly the whole of the plantation would be spoiled because the trees would be drawn up too weakly to be of real value. Then again the Larch disease is a terrible scourge where it attacks a plantation badly. In our particular case I have come to the conclusion that one cause only is answerable for our trouble in that direction, viz.—stagnation about the roots, or in other words unhealthy conditions. Spring frosts, damaged bark and insect pests are all pegs to hang excuses upon.

The elevation here is 400 feet above sea-level. The soil varies. In some fields there is from 1 foot to 2 feet of stiff, stony soil overlying a hard pan of almost clay; below this is a bed of chalk. To look at the soil as moved for agricultural purposes the stranger would say that Larch would revel in such soil. And so they do for fifteen years or so, making leading growths of from 2 to 4 feet in a season. After that period canker appears, and it is worse in the trees on some sites than those on others. That is in my opinion the time when the roots have got down to this hard pan, or subsoil. The water from excessive rains cannot percolate away quickly enough for the welfare of the roots. I know this is the case, because where the soil has been trenched from 2 to 3 feet deep or more canker is unknown. Some may say, Why not employ the remedy? I say in reply, It will not pay to do so. The cost of trenching such soil would be ruinous. Acres and acres of Larch that have arrived at that stage have been cleared as useless, and the land returned to agriculture, under which it is much more profitable.

If Hazel is planted, what are the results from a well-grown crop? Ten years are required to produce a growth suitable for local use, such as sheep-hurdles, hoops for casks, thatching-spars, &c. For this the handsome sum of £3 to £5 per acre is realised, and for ten years' growth.

As an experiment my employer, Mr. W. H. Myers, M.P., planted 2,000 *Thuya gigantea* alternately with Larch. The trees have made quite good progress, but of their value as timber-trees, or even for use on the estate as fencing, I think little of them. From other sources on the estate I have cut trees of this variety 30 feet high, but I find the wood is very soft at that age, and when the trees are stocked after being cut a time they become exceptionally light, which is not an indication of durability.

Scotch, Corsican, and Austrian Pines have all been tried, as well as Spruce. All grow fast; but of what value are they? At the most 4d. per foot is the price obtained. For ornament or shelter all are interesting and useful. As a wind-guard, the Austrian Pine is unsurpassed; but as a timber-tree it is perhaps the worst—it produces too many branches, and these are too near together for the timber to be desirable.

I could continue my narrative of ill-success, but sufficient has been said to warn would-be planters to think twice before they embark largely. *E. Molyneux, South Hants.*

ALDENHAM.

It is doubtful whether there exists in the kingdom a finer private school in which to study arboriculture, so far as relates to that phase of it illustrated by choice trees and shrubs, than that furnished by Lord Aldenham's beautiful gardens and grounds at Elstree. Not only is the owner a lover of trees and shrubs, but his son, the Hon. Vicary Gibbs, is a great authority on them; and endless as seems to be the variety there gathered from all parts of the world, yet Mr. Gibbs knows them and can call them all by their names. But a striking feature of the planting at Aldenham is its complete association with decorative aspects. Really, it would seem as if this feature had been the primary aim of the planters, everything is so harmonious. Yet such a suggestion would probably be disregarded, as after all it would seem that in finding the most fitting site or place for each tree or shrub, the decorative effect had naturally followed. To indicate the varieties planted at Aldenham would need a big volume, and no one however devoted to arboriculture can see them all in a day. Really the collection becomes a school, and it may be hoped may be preserved as such for horticulture for all time.

The owner of Aldenham has been fortunate in securing for a gardener one so thoroughly sympathetic as is Mr. E. Beckett. Not only does he too, seem to know everything, but he appears, like his enthusiastic employers, to know no finality.

To the ordinary visitor, however, fond of trees and shrubs and of hardy plants of all descriptions also there may seem to be enough of everything, but that can hardly be; new forms still seem to be constantly cropping up, and room must be found for them. Established things grow apace and need more room, for crowding is not tolerated here; indeed, one of the special charms of the planting is that each plant has room, and thus can not only display its full character, but, being thus individualised, each specimen commands all the greater interest. The abundance of water brought here and there in lakes large and small, in moats, streams, or rivulets, with here and there much effective rockwork, enables myriads of aquatic or semi-aquatic plants to be grown in great luxuriance. The extent of the well-kept grounds thus utilised seem to be illimitable; rich verdure is everywhere, and with

beds, borders, or plantations, all is kept clean and neat. It is a happy circumstance that, allied to such devotion to arboriculture, there should be such refined taste shown, for the most captious cannot but be delighted with the perfection of keep found on every hand.

In the hardy plant department and the kitchen garden the borders are rich with perennials. A

One of the most effective of June-flowering perennials is *Inula glandulosa fimbriata*, 20 inches in height, flowers large, charmingly fimbriate, and of a rich orange colour. *Anchusa italica superba*, plants 2 feet in height, is here a very fine form, and much superior to the tall, loose-growing varieties often seen. Both the double-white and

grow vegetables, he drained, trenched, buried down deep trimmings of all descriptions, and added to the ground other material wherever obtainable, also wood-ashes, old mortar rubbish, leaf-soil, and manure, until now the level of the garden quarters is 15 inches above its original plane, and thus it is that vegetables of the very finest quality are produced.

Runner Beans planted quite thinly here grow so tall that the rows are all staked with Hazel-branches 12 feet in height. Peas also grow very tall, for Mr. Beckett, giving the rows ample room and tall supports, holds that one tall row is better than two dwarf ones. His own raised Pea Edwin Beckett is in full bearing 5 feet in height, and Aldenham, 6 feet in height, is following suit; but a grand seedling from these two Peas, not yet named, carries such superb pods with eleven and twelve Peas in them that even Aldenham is quite eclipsed. This Pea promises to be the finest exhibition-variety in cultivation. Onions, both autumn and winter sown, are in splendid form, and of the best varieties. Vegetable-Marrows are here from plants running loose after being raised under frames, fruit very freely. In every department the same high culture is seen, and associated with successful exhibiting may be found perfect culture everywhere, nothing being neglected. A. D.

FIG. 23.—BORDER CARNATION BOB ACRES: COLOUR OF FLOWERS SCARLET. (SEE P. 72.)

striking feature by-and-bye will be the long, broad border specially devoted to Asters, of which there is a collection of some hundred of the best varieties obtainable. The plants are lifted, divided, and replanted each year, the growths being not only thinned, but well tied out to some four to six sticks per plant, and in that way flowers of the finest quality are obtained. The plants are 4 feet apart, and there are about 250 of them.

purple Rockets are plentiful here also, but these are merely a few plants out of a great collection.

Mr. Beckett has won most fame in horticulture as a vegetable grower. He began a successful career many years ago in the great conservatory at South Kensington, in contending with so accomplished an exhibitor as the late Mr. C. W. Miles, of Wycombe Abbey, and at Aldenham he has reached the apex in competitions. Faced with a stiff, cold, ungenial soil, which in prior days would not

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from p. 21.)

May 3.—A lovely night succeeded a lovely day. We left our last night's moorings at 5 A.M. and arrived here at 11.30 A.M. Owing to a strong head-wind we were obliged to remain here. The river was rising, and the current in the gorge was too strong to stem with the wind against us. Our last night's moorings were very uncomfortable, the wash and swirl of the river caused us to bump against the shore in an unpleasant manner, and once or twice I awoke with a start.

In the late afternoon I went for quite a long walk along the fine broad road which runs through this gorge on the left bank. It is a well-paved road, cut out of the solid rock, a good three paces broad, and high up above the high-water level. It is in a splendid state of repair. It was built by a widow in memory of her husband, and must have cost an enormous sum of money. Much blasting and building up have had to be done. This and the road through part of the Wushan Gorge represent engineering feats of which no country need feel ashamed.

During my walk I collected several fresh plants, and noted the Pomegranate naturalised on the cliff. It was very common. The fresh plants included—

Solanum xanthocarpum, *Embelia Ribes*, *Saponaria Vaccaria*, *Citrus japonica*, *Ligustrum strongylophyllum*, *Wikstromia micrantha*, and *Cynanchum* sp.

The last-named is the species noted before with opposite leaves. Its flowers are small and yellow in colour. *Embelia Ribes* is the commonest shrub on the rock just above high-water mark. *Citrus japonica* "Kumquat" was common on the cliff, and evidently spontaneous. The common trees hereabouts were—

Pistacia chinensis, *Gleditschia sinensis*, *Sapium sebiferum*, *Alcurites cordata*, *Cupressus funebris*, *Ficus infectoria*, Loquat, Orange, Pomeloe, Plums, and Peaches.

The fruits of the Loquat were just colouring, and the leaves of the Tallow tree (*Sapium sebiferum*) just unfolding. A kind of Wheat new to me, having long and bluish-coloured ears, was grown hereabouts.

May 4.—The wind died away during the night, and it was dead calm when we started through the gorge at 5 A.M. This gorge is to my mind the grandest of all; its cliffs are frightfully steep and almost devoid of vegetation. One

overhanging peak is fully 2,500 feet high. The river has a very tortuous course through this gorge, so much so indeed that a fair wind may become a head wind ere the end of the gorge is reached. There are many legends connected with this valley dating back to the time of the "Three Kingdoms," some doubtless with a dash of truth in them.

Opposite the "Goose rock," or rather looking down on it, is a hill some 500 feet high, crowned with a grove of Pistacia and Banyan trees, in the midst of which nestles a famous temple. This temple is said to be 1,700 years old, and tradition has it that it was here the famous hero Liu-Pei died.

At 1 o'clock we were opposite the salt-wells. These are situated right on the foreshore, and it is only possible to work them in the low-water season.

At 3.30 P.M. we reached the famous city of Kiu-Fu, which is now a mere fragment of what it was in the days of the "Three Kingdoms." We moored for the night here, and having complied with the custom of giving the crew a small gratuity, everybody was happy.

Although slightly north of Ichang, the seasons are earlier here. This is partly due to its being closed in by mountains, and partly to the nature of the soil; the latter is of a brick-red colour and very porous. The Wheat and Pulse crops were being harvested, and we purchased ripe Cherries, but they had little or no flavour. The Irish Potato was largely planted, but looked very weakly. Maize was cultivated, but I saw no Opium, and very little land prepared for Rice.

On the right bank were some magnificent groves of Bamboos. I noted several large trees of the "Litchi" cultivated; and the trees of Orange and Loquat are larger than I have met with before. In a garden attached to a farm-house I remember seeing some large trees of the double-flowered Peach, the only large trees of this kind I ever saw. The flowers were peach-coloured or crimson, sometimes half-and-half, but more frequently striped. Rosa Banksie was very common here, and is the first of the Roses to bloom.

The only new plant I gathered to-day was *Viburnum buddleifolia*, a species apparently intermediate between *V. utile* and *V. rhytidophyllum*.

Kiu-Fu is a famous mart for vegetables, and our crew seemed intent on loading the boat down with them. What they intended doing with all the Cabbages purchased passed my comprehension.

May 5.—We had to get three fresh coolies at Kiu-Fu, and this procedure, together with a thunder-storm, delayed us till 9 A.M. The officials in this province seem very careful with foreigners. The magistrate here insisted on sending a soldier with us to the next district town—an unnecessary honour which has to be paid for.

We experienced much difficulty from shallows to-day, and passed a couple of junks badly ashore. We moored for the night at the village of Anping-just, below which is a nasty rapid called La-Pa-Tan.

Anping is a wretched little village, situated on the side of a steep hill well above high-water mark. Iron is worked inland from here, and is brought to this place and sent upwards and downwards. This and Chinese macaroni are the only articles of trade the place boasts.

During the forenoon I noted some men washing for gold. The quantity obtained is very small, the men being only able to earn a hundred cash (about 3*d.*) per day each. In my walk I noticed much land being prepared for Rice, and also a nice lot of Opium. The latter was just being cleared off the ground to make room for Rice.

I gathered several fresh plants to-day, includ-

ing *Sterculia platanifolia*, *Vaccinium* sp., and a new species of *Elæagnus*. This latter was a bush 4 feet high, with pure white flowers, and leaves smaller and thinner in texture than any other species I am acquainted with. Small thickets of Scrub Oak (*Quercus chinensis*) were common, and *Diospyros Kaki* was commonly cultivated. *Cupressus funebris* continued practically the only Conifer.

May 6.—A heavy thunderstorm, which began about 4 A.M. and lasted till 8 o'clock, delayed our start till 8.30 A.M. The rain fell in torrents, and water was pouring into the Yang-tsze on every side. This water was a bright copper-red, a sign we are within the red-basin of Szechuan. The red-basin extends a little west of Kiu-Fu; and includes within its limits more than half of the huge province of Szechuan—in fact, it may be appropriately applied to almost the whole area of eastern and central Szechuan. It owes its name to the preponderance of red clayey sandstone and sandy clays of enormous stratigraphical development which impart their characteristic brick-red colour to the surface when it is exposed. The soil is remarkably rich, and it is to this that Szechuan owes its enormous wealth as an agricultural province.

A fair wind sprung up about 10.30 A.M., and we made good progress until a heavy shower forced us to tie up at 2 P.M. The wind then veered round and blew down the river. Starting again at 3.30 P.M., we got over Miao-che-tsze rapid safely and moored two miles above it. This Miao-che-tsze rapid is situated just above the village of Kulin, and is one of the worst during the low-water season. It annually becomes more difficult from the *débris* brought down by a small torrent.

On the south bank is a pretty temple nestling inside a grove of Cypress and *Melia Azedarach*, which crowns the rocky knoll. The "Pride of India" was in full flower and made a startling display. The trees were some 15 to 20 feet high, and the size of the panicle of flowers enormous. It does not appear to grow into large trees, at least not in the Yang-tsze Valley. *Aleurites* and *Pistacia* trees were again common.

May 7.—It rained gently all night, and it was just after six o'clock when we made a start. The country is still very hilly, but the hills are not so high and the slope more gradual. Every possible place is cultivated. At 11.30 A.M. we passed the town of Yung-Yang. This place is surrounded by a good wall, though most of the people appear to prefer to dwell outside it. Much of the land inside the wall is devoted to various crops. This city, in the time of the "Three Kingdoms," offered a very stubborn resistance to Liu Pei. This genius eventually took it, and marched on Cheng-tu. On a high hill overlooking the town is a fort, one of a large series which were built at the time of the Taiping rebellion. The trade of Yung-Yang consists of opium and salt. It boasts several fine buildings, one of which has a very ornate exterior. The Roman Catholic fathers are busy building a large school here.

On the right bank and facing the town is a very fine temple, dedicated to Chang Pei, a famous general, and half-brother to Liu Pei. One of the features since entering Szechuan has been the abundance of the Irish Potato; it is grown everywhere, and is undoubtedly a valued crop. The haulms are very weakly. They are planted far too thickly, and seldom if ever is any attempt made to earth them up.

On leaving Ichang I engaged a crew of twenty-four hands—seventeen trackers and seven deck hands. Only twice was I able to count this number. The deficiency was always amongst the trackers. The reason was always the same—"They run away." This often was so, I know; but the real reason was that every man short meant that man's wages in the pocket of the head tracker.

I poured vials of wrath on their heads, but all to no purpose. To satisfy me they told some plausible tale, and afterwards got the requisite number of men for a time.

We reached the Hsin-Lung-Tan (New Dragon rapid) at 5 P.M., ascended it, and moored for the night. This rapid was formed by a landslide in 1896, and at low-water ranks with the Hsin-Tan as the worst rapid on the river. With the water at its then existing height it was quite a small affair, and I could scarcely persuade myself that it was the same frightful rapid I first saw in March, 1901.

The only new plants to-day were *Onychium japonicum*, *Boltonia indica*, *Vitis* sp., *Adina globifera*, *Sedum* sp., *Diospyros* sp. nov., and *Vitis inconstans*. The last-named with simple and trifoliate leaves was common on the cliffs. The ubiquitous funeral Cypress, *Aleurites* and Banyan, together with *Quercus chinensis* and *Ehretia macrophylla* were the principal trees.

E. H. W.

(To be continued.)

COLONIAL NOTES.

HEATING OF PLANT HOUSES.

THE present system of heating plant house boilers by means of coal seems to be unworthy of the progressive age in which we live. In the first place the smoke is a nuisance, especially in a place of purity and sweetness, such as a garden should be. The boiler-house and coal store are unsightly; the labour of stoking and carting coal is unnecessarily laborious; the danger from sparks is in this climate sometimes a real one, while the fire cannot be shut off in time of danger. It seems to me that there is abundant scope here for the substitution of gas for coal as a fuel, especially in towns where gas is readily available. Can any of your readers inform me of an effective gas-installation, on a fairly large scale, of the kind to which I have referred? *J. H. Maiden, Director Botanic Gardens, Sydney.*

COOMBE HOUSE, CROYDON,

THE pretty residence of Frank Lloyd, Esq., is less than a mile from the large town of Croydon. On entering the grounds by the front lodge there is a bank thrown up several feet in height, on which are good forms of Ivy and varieties of Lord Penzance's Briars. These have plenty of room to show their beauty in a perfectly natural manner. Close by is a fine clump of the Thimble-berry. In some beds on grass at the other side of the bank are some fine examples of Roses, such as *R. Wichuraiana*, *R. polyantha*, *Royal Scarlet*, *Persian Briars*, *Ramblers* over arches, all in the very best possible condition.

In a corner I notice a fine plant of *Prunus Pissardi*, with a well-flowered Rose in the foreground—a lovely picture. A good many beds are filled with all the choicest varieties of Teas, H.T.'s and H.P.'s. Near by is a magnificent *Acacia* with a mass of white flowers and surrounded by large trees of *Abies*, &c., which add to its magnificence.

In the rock garden are some fine clumps of rock Roses, of which *H. Pelisse* and *Bridesmaid* are conspicuous. A cross from these two varieties, effected by Mr. Lloyd, has beautiful bright salmon-coloured flowers. The beautiful *Onosma tauricum* is very pretty, also a fine lot of alpine Poppies. In an herbaceous border adjacent are some fine *Spiræas*, notably *S. Aruncus* and *S. aquilegifolia*; the former is a mass 5 or 6 feet in diameter. The beautiful *Iris Mrs. Neubronna* (yellow), is conspicuous amongst all the best sorts. An extraordinarily fine batch of choice *Delphiniums* decorates another border, and a large collection is also in evidence in another quarter.

In the kitchen garden (No. 1) is the most gorgeous sight of all, consisting of a grand collection of *Pæonies*; there are 150 plants which

have borne 4,000 blooms. The blooms are perfect and the scent delightful.

In the glasshouses plants are largely grown for house and conservatory decoration. In one house is a fine batch of the *Begonia Worthiana*, of which a group of plants was awarded a Silver Cup at the recent Temple Show. These handsome flowers are being yearly improved upon in form and colour.

In an adjoining house are some *Codiaeums*, amongst which are several very good seedlings, raised here by Mr. Mills the head gardener. In another house is a very fine batch of *Calanthes* and some *Cypripediums*. Good and healthy plants are noticed of *C. Rothschildianum*, *C. Veitchii*, *C. Lawrenceanum*, &c., also some *Cattleyas*, *Dendrobium nobile*, and others of the section are looking well, making grand growths. Some specimen *Codiaeums* (*Crotons*) are in the centre of the house, and a fine plant, some 10 feet high, of *Dracena Sanderiana*, some very good *Cymbidium*s, also a lot of *Paneratiums* and *Begonia Gloire de Lorraine* (*Coombe House var.*). In another house the cool-growing *Orchids* are looking very robust. Fruit is not cultivated extensively indoors at Coombe, but crops of Peaches, Figs, &c., are grown on the walls out-of-doors.

Some thousand *Chrysanthemums* are grown, and Mr. Mills does not propagate them until March; the plants are in very fine vigour, and he seems justified by results, as he has gained many medals, prizes, and cups. All his plants have not been grown this way till this year.

On the lawn in front of the mansion are some fine old Cedars, which are in a delightful state of preservation. The low branches are pegged to the ground, and the interstices planted with Ivy, which has a charming effect.

Two beds are filled with fine plants of *Rosa polyantha Leuchstern*, the flowers of which are of bright rose colour. The long branches laden with flowers and hanging loosely over the beds are exquisite. Other handsome varieties are to be planted in like manner. Mr. and Mrs. Lloyd are extremely fond of many plants, but of none more than *Roses* and *Paeonies*. *W. A. Cook, Shirley Park Gardens.*

PLANT NOTES.

GLORIOSA ROTHSCHILDIANA CITRINA.

A BEAUTIFUL novelty, widely distinguished from any other *Gloriosa* in colour, is now in flower in the Right Hon. Lord Rothschild's gardens at Tring Park (gr., Mr. A. Dye). In form it is similar to the typical *Gloriosa Rothschildiana*, illustrated in the *Gardeners' Chronicle*, May 23, 1902, p. 323, and its flowers develop in a similar manner—that is to say, the segments are at first reflexed, and as they approach maturity they assume a horizontal position. On opening, the blooms are of a clear citron-yellow with a feather-like band of deep claret colour up the middle of each segment. As the flower matures the claret colour suffuses more of the yellow tint until when the flower is fading the whole has become tinged with claret colour. The bright citron-yellow is quite different to the more or less buff-tinted yellow of other *Gloriosas*.

Typical *G. Rothschildiana*, with its rich ruby-crimson flowers, is also in great beauty, and some forms of it out of a recent importation, but so far the original is the best, although the more recently imported are not yet strong enough to appear to advantage.

At Tring Park the *Gloriosas* are used for dinner-table decoration, and few flowers are so well adapted for the purpose, if cut with their own foliage. *J. O'E.*

ODONTOGLOSSUM CRISPUM.

MESSRS. SANDER have sent us from Bruges a malformation of this species, such as we have never met with before, though "median proliferation" is exceedingly common in other flowers. The perianth segments, numbered in the diagram (fig. 24) from 1 to 6, present no special peculiarity beyond the fact that the lip is represented by an ordinary flat segment. The inferior ovary and the column are wanting, the centre of the flower being occupied by a tuft of adventitious flower buds on short stalks, numbered 1. to vi.

The illustration shows one of the flowers of the natural size, with a diagram showing the arrangement of the parts, and one of the adventitious flower-buds slightly enlarged. The growth of

FIG. 24.—PROLIFEROUS FLOWER OF ODONTOGLOSSUM. (See Text.)

the central axis of the flower, instead of stopping short, has gone on and produced a tuft of buds as in an ordinary spike.

FRUIT REGISTER.

TWO NEW STRAWBERRIES.

"LAXTON'S LATEST 1904" was kindly sent me for trial in 1903 and fruited last year, when I formed a very high opinion of its merits. This opinion is amply confirmed this season. The plants yield a heavy crop of large, wedge-shaped fruits, of a dark crimson colour, which runs right through the fruit. The flesh is very solid, of excellent flavour, and ripens later than *Waterloo*. Several fruits weighed 1½ oz. each, and measured 6¾ inches in circumference. It is without doubt the finest late Strawberry known.

Bedford Champion yields a very heavy crop of large, round, firm fruits of a bright red colour. The plant is a vigorous grower, more compact in habit than *Royal Sovereign*, which ripens about the same time. Its general character is well represented by fig. 18 on p. 43 in the *Gardeners' Chronicle* for July 15. This variety will be a good one for market growers. *W. H. Divers, Belvoir Castle Gardens.*

THE ROSARY.

ROSES AT LOWDHAM.

CLIMBING ROSES have grown in favour immensely since the introduction of *Crimson Rambler*, and many varieties have been added to this section in order to meet the increasing demand for them. The following varieties were noted in flower during a recent visit to Messrs. Pearson & Son's Nursery, Lowdham, Notts, where an erection has been built in order to afford means of conveying a correct idea of the value of different varieties for covering pillars, pergolas, &c.

Gloire de Margottin.—Very bright red, a full flower, and a good grower.

Rubin.—Bright purplish-red, very free, similar to *Fellenberg*, but more purple in colour, effective at a long distance.

Morgenrot.—A fine single red flower, better than *Carmine Pillar*.

Una.—Single white, very free-flowering.

Conrad Meyer.—A very strong grower, flowers of bluish colour. It belongs to the *R. rugosa* section, but covers a pole well.

Leuchstern.—Rosy-pink with white eye, single, flowering in clusters. One of the best.

Dorothy Perkins was not in flower, but is well known, and ought to be in every garden.

Ards Rover.—Single red, fine large flower, and possesses a good constitution.

Francois Crousse.—Of bright red colour, full flower.

Climbing Captain Christy.—Similar to the ordinary form in its flowers, but this is a good climber if obtained true.

Meg Merrilies.—One of the *Penzance Briers*, very fine as seen here on a pole. Of deep pink colour, single, it is also valuable for planting as a single specimen in a "wild garden," and is capable of forming a huge bush.

Anne of Gierstein.—Another *Penzance hybrid*, very similar to the above, but deeper in colour.

Among dwarf varieties, hundreds of which were in full flower, I noted the following:—*Madame Ravary*, T., yellow, very good; *Florence Pemberton*, H.T., bluish, very fine; *Lady Moyra Beauclerk*, rose-coloured; *Madame E. A. Nolet*, a very free bloomer; *Le Progrès*, yellow, full of flowers; *Mrs. Jas. Hill*, having a nice long bud of bluish colour and very promising; *J. Campbell Hay*, H.T., pink, a good variety, with large foliage; *Lady Ashtown*, of pink colour, a finely-shaped bud; *Mamie*, H.T., a fine full flower.

Many older varieties were looking extra well, and all were very clean and healthy. A Rose with a perfume of *Violet* is a novelty to many; it is called *Eugénie Lamesch*, and has small pink, yellow, and white flowers in clusters; this is a pretty variety, belonging to the dwarf polyantha class.

In addition to the *Roses*, I could not help admiring the fruit-trees which are distributed in large batches over the 100 acres forming the nursery, all clean and healthy; and a peep at the Vermorel spraying machines explained part of the reason why such a success has been achieved. *W. H. Divers, Belvoir Castle Gardens.*

NOTES ON VARIETIES.

The present Rose season, so far as my own observations extend, has been distinguished by the brilliancy of the *Hybrid Perpetuals*, and the comparative failure of the more delicate *Teas*. Here the most successful among the latter have been *Anna Olivier* in the garden, and *Devoniensis* at the study-window; both of these exquisite varieties have been exceptionally fine. Of the *Noisettes* the most conspicuous, by reason of its floriferousness, has been *Bouquet d'Or*; almost

rivalled in productiveness, and quite eclipsed in perfect purity and sweetness, by its aspiring companion, Madame Alfred Carrière, one of the loveliest of Hybrid Noisettes. William Allen Richardson and L'Idéal have not as yet florally achieved very much, but they are full of promise for the early autumn months. Just at the crucial period when they were beginning to grow they suffered very greatly from lack of rain, without whose truly beneficent ministrations the strongest and most vigorous varieties will not adequately succeed. This season has been generous in the direction of heat, but moisture has been very conspicuous by its absence.

As previously indicated, the Roses that have grown and flowered most effectively under such trying conditions have been the Hybrid Perpetuals and Hybrid Teas. Of the former the grandest in their floral impressiveness have been Frau Karl Druschki, some of whose satin-white flowers in my garden have been nearly 7 inches across; Margaret Dickson, perhaps the most effective Rose for garden-culture that the famous Newtownards Rosarians have produced; Clio, a very beautiful and grandly growing Rose, a native of Waltham Cross; A. K. Williams, which is not invariably reliable at first, but generally improves, and is always seen to best advantage during the autumnal months; Charles Lefebvre, which was a special favourite of the late Dean Hole, and when seen at its finest is not easily surpassed; Duke of Edinburgh, Horace Vernet, and Lady Helen Stewart, three of the loveliest of velvety crimson Roses, which have recently found a formidable rival in a luminous Newtownards namesake of my own. Very prominent among pink-coloured varieties have been Mrs. Sharman Crawford and Mrs. John Laing. I have hitherto regarded Mildred Grant as essentially an exhibition variety; in the garden its flowers are certainly enormous, with rugged shell-petals, but they are comparatively few.

The finest in Scottish gardens of the Hybrid Teas this season have been Caroline Testout, La France, and Clara Watson, which combine the richest fragrance with splendidly commanding floral effect; Madame Pernet Ducher, whose deep colour in bud-form does not suggest its subsequent pure white revelation; Papa Gontier, an invaluable rose, beautiful at all stages of its exquisite evolution; Viscountess Folkestone and Gloire Lyonnaise. I should have given Captain Hayward highly honourable mention among the most distinguished of the Hybrid Perpetuals. David R. Williamson, South-west Scotland.

The Week's Work.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Club-stemmed Dendrobiums, as *D. thyrsiflorum*, *D. densiflorum*, *D. Farmeri*, and other similar plants, are termed, comprise a number of excellent species that are admired whenever they are seen in flower. It is now their season of growth. They need a good share of heat and moderate light, but not a large amount of atmospheric moisture, or water at the base, until root-action occurs, which will be when the club-shaped pseudo-bulbs are nearing completion. The necessary potting operations should be given attention soon after growth commences, or just as the roots emerge from the bases. Let the pots be drained to two-thirds of their depth, and use a compost of good peat two parts and sphagnum-moss one part. Being of rapid development, the compartment they occupy must be well ventilated, but free from draughts and sudden fluctuations of temperature, or the young tender foliage may become spotted. When the pseudo-bulbs have reached their full size diminish the supply of water, and remove the plants to cooler and drier quarters, such as a Cattleya-

house affords. On the approach of winter a dry and moderately airy position may be found for them in a vinery or elsewhere, and throughout the long resting period only give water when signs of shrivelling appear in the younger pseudo-bulbs.

Dendrobium moschatum, &c.—The species named is a strong-growing kind that delights in an abundance of heat, light and atmospheric moisture during its growing season, therefore let the plants be placed in an ordinary plant stove. Once established in a good-sized, well-drained pot, only annual resurfacings of good peat and sphagnum-moss will be necessary, applying this just as new roots emerge from the young growths. At this period a liberal supply of water at the base is needed, but only limited applications at other times. Provided the position suits the plants, they may remain in the warm-house throughout the year, if it can be kept very dry during the winter and spring months. *D. Dalhousianum* needs similar treatment in most essentials, though perhaps dryness at the base should be maintained for longer periods. *D. chrysoctoxum* and *D. suavisimum* are also heat-loving species, and may be treated like those already noticed, though if convenient somewhat cooler and drier quarters may be given them during winter.

Resting Dendrobiums.—Such early-growing species as *D. Wardianum*, *D. crassinode*, *D. primulinum*, *D. aureum*, &c., will in many instances have finished growing, and should be given the treatment that will ensure a thorough ripening of their pseudo-bulbs. The first two species may be removed to a vinery where more light and air are obtainable as soon as the terminal leaf is seen. Continue to afford an abundance of water, and syringe the foliage to keep it free from insects. As the foliage loses colour and begins to fall away, decrease the water supply until it is only needed at long intervals. *D. primulinum* may be suspended in a Cattleya-house, and be treated similarly to *D. crassinode* and *D. Wardianum*. *D. aureum* may remain where it has made its growth, but as the pseudo-bulbs mature very much less water will be needed, and when the leaves turn yellow and fall away apply little or none until the following season.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Asparagus Seedlings.—If seeds were sown in their permanent quarters, let the plants be thinned to 12 inches apart that they may grow sturdily. Destroy weeds by a frequent use of the hoe.

Endive.—As many of the early-sown plants are likely to bolt, make a liberal sowing now in good rich soil. Let the early plants be well blanched before they are used for salading, otherwise the leaves will be very bitter. A simple and effectual method of blanching them is that of placing a broad board in such a position as to rest on the plants.

Tomatos will still require attention at least once a week in the removal of all lateral growths. The single stem system is the best. By regular tapping each plant-stem or the stake occasionally when the plants are in bloom, or by means of a piece of fur attached to the end of a stick, help to secure the better distribution of the pollen. Do not allow the soil to become too dry, but bear in mind that much water at the roots or on the stems and foliage is not favourable to Tomato culture. The practice of trimming the leaves by the wholesale removal of healthy foliage we do not practise, and do not recommend. The removal of a few leaves here and there to admit light is permissible.

Cucumbers that are growing in frames need somewhat different treatment to those grown upon a trellis in a house. Space being more limited, the main stems must be stopped more frequently to cause the development of side shoots, which will soon show flowers. When one or two fruits have developed the shoots should be stopped a joint beyond the fruit. Admit as much light as possible to established plants, and afford them considerable water when they are fruiting. Syringe the foliage frequently, for a dry atmo-

sphere would favour the attacks of red-spider. Avoid over-crowding by removing early all matured vine and foliage, there may then be expected a succession of young and vigorous shoots that will bear fruits.

Ridge Cucumbers now growing freely in a warm sheltered position should be afforded water freely. Do not allow the shoots to become over-crowded, nor let the fruit be too old before cutting, fresh young fruits being much the best.

Broccolis and Kales.—The planting of several kinds of Broccolis and Kales should now be completed. Firm ground will afford the best results.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

The Conservatory.—Every opportunity should be embraced for tying and for thinning overhead creepers. Afford these plants copious applications of diluted liquid manure from the drainings of the farmyard, and apply the same early in the morning when a free circulation of air will soon remove any disagreeable smell.

Specimen plants of *Allamandas*, *Clerodendrons*, *Bougainvilleas*, &c., that have completed this season's growth may be removed to cooler quarters, and allowed full exposure to sunshine, the better to ripen their growth. Specimens planted in the borders and trained over the roof should be well thinned out, in order to allow a free circulation of air to pass between the growths.

Clerodendron fallax.—Seeds of this plant are freely produced, and sufficient should be allowed to ripen from plants now passing out of bloom for next year's sowing. No advantage is gained by retaining the old plants for flowering a second season, but sufficient should be saved to afford a supply of cuttings for propagating purposes early in the spring. Plants intended for flowering in the autumn will be benefited by an occasional light dressing of Clay's fertilizer.

Glorinias.—As these plants are removed from the conservatory or flowering-house they should be placed in a cool frame where they can ripen. They should also be fumigated to destroy thrips or other insects present. Diluted liquid-manure should be afforded them until the foliage shows signs of decay.

Fuchsias.—Plants intended for furnishing cuttings for autumn propagation will require to be thoroughly ripened, therefore they should be stood out-of-doors in a position where they will be fully exposed to the sun's rays for a week or two, after which they should be shortened back and started into growth. By this treatment suitable cuttings will be available early in September.

Bouvardias, *Salvias*, *Libonias*, &c., that are planted in ashes or planted in the borders will occasionally require pinching, they should also be afforded copious supplies of liquid-manure. Overhead syringings with clear water morning and evening during very hot weather will be of great benefit to these plants.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Pears and Apples.—These trees require an abundance of water, and should be examined several times daily, or they may be removed to the open air and the pots partially plunged in the soil. The fruits will ripen well in such conditions. Continue to pinch the shoots, in order to assist the formation of fruit-buds for bearing next season.

Cherries.—The trees of all except late-fruited varieties will have been cleared of fruit, and may be taken out of the house and the pots plunged in the open ground. Syringe the trees daily, and afford water to the roots as often as it is necessary. Afford abundance of air to late varieties, and do not permit too much atmospheric moisture when the fruits show signs of ripening.

Plums.—Afford later varieties of Plum-trees more room after early varieties have been removed out of doors, and stage them by themselves, if possible. Keep the shoots closely pinched; apply diluted liquid manure and guano-

water to the roots alternately. Syringe the trees with soft water only or the "bloom" on the fruits will be damaged or destroyed.

Melons.—The present season has been a good one for Melon culture, there having been plenty of sunshine, therefore with careful attention to watering and ventilation high flavour has been obtained in the fruits. In dull and wet weather greater care is necessary in damping and ventilating, or canker is liable to appear. In the structure where fruits are commencing to ripen, keep the atmosphere moderately dry, and maintain a free circulation of warm air. Cease to apply manure-water, but afford clear water in moderation. Plants make more lateral growth at this season, even if the rooting medium is a limited one, and they should be examined at least once a week that the laterals may be removed. Apply liquid-manure or some other stimulant to plants carrying heavy crops of fruit, regulating the supply in accordance with the amount of leaf-growth and the quantity of soil the roots have for growing in. Close the house early in the afternoon with plenty of atmospheric moisture. Where Melon-fruits are required late in the autumn, and good houses are at command having means for providing plenty of top and bottom heat, a sowing of seeds should be made now, selecting a strong growing and quick maturing variety. Good varieties of Melons are numerous, but those who have not grown Veitch's Late Perfection for ripening very late in the season should try this excellent variety. The late Melon-plants should be either planted out as recommended in previous Calendars, or be grown in pots. Encourage them to make sturdy growth by affording freer ventilation on all favourable occasions than is generally recommended for Melons.

Melons in Frames.—Remove all surplus growths as they appear, and avoid injuring the principal leaves. Raise the fruits on inverted pots to give them full exposure to the light. Any plants that are in flower should be kept in slightly drier conditions until the fruits are set. Top-dress the plants with loam if necessary, but this will depend upon the depth of fermenting material, and the quantity of compost given them in the first instance. Syringe the plants and close the frames early on bright afternoons, and when the roots need water apply liquid-manure or guano-water, but be careful not to apply too much water in dull or unsettled weather.

Tomatos.—Make a sowing of seed to raise plants for fruiting in the winter. Two good varieties for this purpose are Frogmore Selected and Sutton's Winter Beauty. Raise these seedlings in a cool pit, and afterwards keep the plants in a nice light position near to the glass, endeavouring to encourage a firm but not a strong growth. Repot the plants into 6-inch pots as they become ready, and remove them out-of-doors to an open position where lights can be placed over them in wet weather. Subsequently repot the plants into 8-inch pots, using a moderately rich compost of loam, wood-ashes, lime-rubble, and a sprinkling of bone-meal. Afterwards they may again be placed out-of-doors for a time.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

The Flower Beds and Borders.—Keep all plants in a growing condition by affording them water in dry weather. Remove the seed-pods from Violas, take away old blooms of Roses, and afford manure and water to encourage the plants to make a good autumnal show. Do not let Sweet Pea or pea pods, but cut all fully-grown flowers. Afford water to the plants.

Carnations.—Prepare compost in readiness for layering, by thoroughly mixing together two barrowloads of loam, one of leaf-mould, and one of river-sand. Let this be sifted through a 3/4-inch siddle. Towards the end of the present month the shoots will be ready for layering. In doing this work clear away the bottom foliage, loosen the soil round the plant, and apply some fresh compost. With a sharp knife make an upward cut through the third or fourth joint in a shoot about half an inch up the centre of the stem. Gently bend the shoot so that the slit becomes well open, press it into the soil, and secure it firmly with pegs made

from twigs of Willow or common bracken. Add a little more soil afterwards, and apply water liberally in dry weather. If birds are troublesome place some stones amongst the layers. These will also act as a mulch to prevent rapid evaporation.

Hydrangea paniculata grandiflora can be propagated by inserting young or partially-ripened shoots into porous soil in a shady frame. Take advantage of showery weather to apply a little artificial manure to established plants.

Roses of the Rambler type.—The strong shoots require tying at short intervals of time. Afford ample waterings. The advantages following deep cultivation are clearly shown when a period of drought sets in. Queen Alexandra, Leuchstern, Thalia, and Euphrosyne are good varieties of the type. Madame Norbert Levavasseur is a dwarf variety with purplish - crimson flowers. The Wichuraianas make graceful weepers on standard Briar stocks. Amongst many good sorts the following are distinct and beautiful: Adelaide Moule, Edmond Proust, Elisa Robichon, Dorothy Perkins, Francois Foucard, René Andry rubra; all are robust growers and splendid for covering ground, owing to their prostrate habit. Rugosa repens alba has single white stellate flowers and pendent growth.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM FLOWDEN, Aston Rowant House, Oxon.

Summer Pruning.—This operation may now be undertaken, although little remains to be done if early attention was given to the pinching and thinning of shoots, as directed in previous Calendars. Examine trees which have been so treated and remove or closely cut back any cross shoots that are not required. All spur growths which were previously pinched and have made considerable growth again should be stopped back to two leaves beyond the previous stopping. In such cases the main branches will be thinly disposed so that the sun's ray can shine perfectly through the tree. Extension shoots that are making a moderate amount of growth only may be left their full length, but to balance the growth of a tree an extra vigorous shoot should be stopped, thus diverting the sap into the weaker ones.

Wall Trees.—Secure the leading shoots whilst they are still in a growing state, for after the growth has stopped it becomes difficult to train a bent or crooked shoot. Cordons, whether of upright, oblique, or horizontal form, should be treated similarly. Attention should also be given to the fruits, and in cases where there are heavy crops make a final thinning of the fruits. Cleanse the trees of any insect pests at the same time.

Neglected Trees.—Trees that have not received the attention that was recommended in previous Calendars will need much more pruning at this date. In order not to inflict on the trees a severe check by the removal of much growth at one time the pruning should be performed at two operations, commencing with the upper portions of the tree first where the strongest growths are found, then in ten days afterwards finishing with the lower parts of the tree. The removal of a large number of shoots from a tree that is in active growth might cause temporary stagnation at the roots, and a loss of vigour to the tree. Trees to be pruned should have their side-branches removed down to the fourth leaf from the base, and this is best done by a sharp pressure of the shoot against the pruning-knife. It is not wise to prune closer than advised, in case these basal eyes commence to grow with the advent of warm, showery weather in August and September.

Syringing Wall-trees.—During hot, dry weather wall-trees should be syringed once each day after 5 P.M.

THE APIARY.

By CHLORIS.

When to add Supers.—For the want of a little knowledge on this topic much valuable time is lost, and often through the crowded state of the hive a swarm issues. When all the frames or sections, save those on the outside, are filled and

sealed, then is the time to add another rack or super.

How to add a Super.—This is a very important point. On many occasions I have seen successful beekeepers create quite an uproar when performing what is to many of us a very simple operation. Never choose a day which is cloudy and the bees are having a slack time, for then they seem more prone to sting. The correct position for the new super is underneath those that are already nearly completed. Place the new super ready at hand, have the smoker well filled and burning furiously, give the bees a slight puff at the entrance and wait two or three minutes; then remove the roof, and as you turn back the quilts, puff smoke across the frames or sections. This done, lift the crates by giving them a slight twisting movement, and lift them gently without jar. Give another whiff of smoke to drive the bees down from the excluder. Having completed this, put on the new crate, place the other or others on the top, cover up snugly, and replace the roof. All this can be performed in a very few moments and without any unnecessary commotion.

How to Remove Crates when Full.—The amateur imagines this to be an easy task, and being anxious to harvest his first surplus, takes off the rack to a little distance from the hives and there leaves it, imagining that whilst he fetches others the bees will be in process of removing. To his horror he finds there is a perfect hubbub, for the bees far and near seem to have scented it, and are helping themselves. Many beautiful sections have been spoiled in this manner, for the bees in their desire to rob, perforate the cappings, and afterwards these "weep," as it is called. Take a board the size of the super, and in the middle place a Porter Bee Escape. Put this under the rack the previous evening and next morning the super will be deserted. Remove it to a safe distance and at the same time cover it. This naturally makes us consider the next process.

Extracting.—Make the extractor clean by rinsing well with boiling water and dry perfectly.

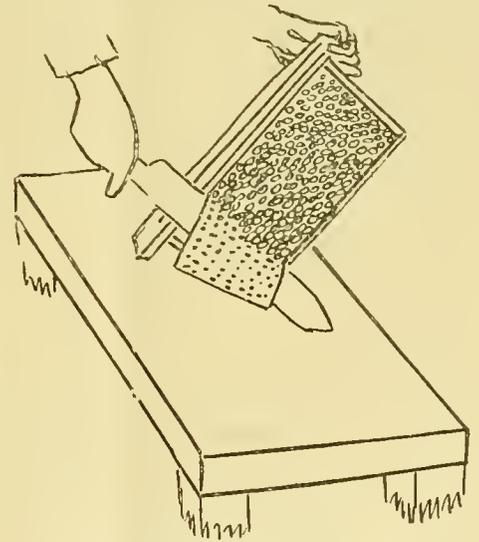

FIG. 25.—UNCAPPING A SHALLOW FRAME OF SEALED HONEY IN ORDER TO EXTRACT THE HONEY.

Oil it well, but not to overflowing, as many do. To secure the best results all honey to be extracted should be in sealed combs. Take a good knife and lean the comb over and cut off the cappings from the bottom upwards, as in the sketch. Perform this operation in the evening at dusk, or you will wish the honey and bees at the bottom of the sea. After all the combs are extracted return the crates with empty combs to the hives to be cleaned out by the bees. If they are left in the open robbing will be the result.

Where to place the honey.—Much trouble has been caused at different times by carelessness after extracting. The honey is often left in the open, so that bees come to help themselves, as also do the wasps. Place the honey in closed tins or jars, and keep it in a warm place.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JULY 26	Cardiff and County Horticultural Society's Exhibition (2 days). Southern Counties Carnation Show at Southampton.
FRIDAY, JULY 28	
	Royal Botanic Society Meet. Handsworth Horticultural Show (2 days).

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63.4°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, July 19 (6 P.M.): Max. 75°; Min. 58°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 20 (10 A.M.): Bar., 30.3; Temp., 73°. Weather—Bright sunshine.

PROVINCES.—Wednesday, July 19 (6 P.M.): Max. 71°; Guildford; Min. 57°, N.E. coast of Scotland.

Roses, Roses, Roses! BEFORE the season of Roses is over it may be well to call attention to many points about Roses and Rose culture which still require elucidation. There are many to whom a Rose is a Rose, and who would resent as profane sacrilege any attempt at analysis or experiment. No one will question their right to enjoy their Roses in their own way. There are others eager to know the how and the why, and their enjoyment is as keen as that of their fellows, with the addition of a greatly enhanced interest and the ever-present anticipation of novelty and perhaps improvement.

From this point of view an article in the current number of the *Revue Horticole* deserves the attention of rosarians. It gives a brief account of the now famous Rosary established at l'Haÿ, near Bourg la Reine, by M. GRAVEREAUX, which was visited by some of the deputation from the Royal Horticultural Society which visited Paris this spring. No fewer than one thousand five hundred varieties, or so-called varieties, are cultivated, a herbarium has been formed, and a library established. But this was only the beginning. The project expanded, and now a collection as complete as possible of all the wild species from every country is being made, a vast correspondence is established, hybridisation and cross-breeding are carried out, a laboratory is proposed, trials instituted, and every means taken to study and to demonstrate the subject in its scientific, artistic, cultural, and even commercial aspects. In the arrangement of his trial grounds M. GRAVEREAUX has had the advantage of the talent and skill of M. ED. ANDRÉ. That gentleman has lately revisited the "Roseraie de l'Haÿ," and, in the journal to which we have alluded, gives a brief account of some of the trials and experiments now in progress. These trials are carried out in beds set apart for the purpose, and their general character can be gleaned from the following brief note:—

Experiments showing the methods of pruning most appropriate for particular varieties.—Four specimens of the same variety are placed side by side. Of these four, one is hard-pruned, the second moderately, the third still less, whilst the fourth is not pruned at all.

Experiments to induce flowering at different periods, e.g., early-flowering, mid-season (normal), late-flowering.

Investigations as to the best stocks.—Fifteen different varieties are used as stocks, the scion being the same in each case. The

Roses used as stocks are *R. laxa*, *canina-rubiginosa*, *arvensis*, *inermis*, *Manetti*, *indica* major, *De la Grifferaie*.

Enquiries as to the influence of different soils.—Soil has been procured from various Rose-growing centres, Angers, Orleans, Lyon, Golfe Juan, Luxembourg, La Brie, Ivry, Villejuif, &c., and the same variety has been planted in each.

Experiments relating to the use of manures.—Various commercial manures are tested comparatively.

Trials with artificial manures of different composition.—For this purpose the Roses of the same variety have been planted (a) in arable land, (b) in pure sand. In each case (a and b) the Roses are grown (1) without any addition to the soil, (2) with a complete manure, (3) with a manure without nitrogen, (4) with one from which potash is excluded, (5) with one into the constitution of which no phosphates enter.

Diseases of Roses.—In this case comparative trials are made of various fungicides and insecticides.

Production of new varieties by cross-breeding.—A special quarter is reserved for the examination of the numerous crosses raised between *Rosa rugosa* and other species and varieties.

Influence of grafting on the production of varieties.—Fixation of sports.

Merits of new varieties.—All new varieties are obtained and their relative merits tested. If judged of sufficient value, they are drafted off into the general collection.

Influence of light-rays of different colours on the growth and colouration of Roses.

Production of perfumes.—Each variety has its special odour.

Colours of Roses.—In a catalogue which is in course of preparation the colours will be described tersely and precisely, so as to be easily comparable.

Classification of Roses according to their perfume.

This is indeed a vast programme, and it may be feared that its projector may be overwhelmed by the amount of detail he has accumulated. Concentrated effort on one or two particular points might yield more satisfactory results. In any case we owe not a little to M. GRAVEREAUX for making plain to us what we do not know about Roses, and what we may expect to know in future as the result of his experiments.

INTERNATIONAL SHOW AT EDINBURGH.—The Council of the Royal Caledonian Horticultural Society met on the 12th inst., when arrangements were further matured for this forthcoming event on September 13 to 15. Already a considerable number of applications for space for non-competitive exhibits has been received. The last date for receiving these is July 27. On the representation of prospective exhibitors the Council has modified the rule as to staging exhibits by 11 P.M., and has now resolved that, with the exception of a few classes of exhibits which are specially mentioned in the schedule, all exhibits must be in the Waverley Market by midnight on September 12, and all staging must be completed by 3 A.M., Sept. 13.

GIANT LARCH-TREES.—Some notable Larch-trees were recently felled at Bedburn, near Hamsterley. About 5 or 6 feet from the ground-level the largest had a girth measurement of 8 feet 9 inches, whilst near the base the measurement exceeded 12 feet. The second largest tree was felled first; its extreme height was 98 feet,

and it was calculated that the largest tree would be a few feet higher. It is estimated that the trees are over a century old.

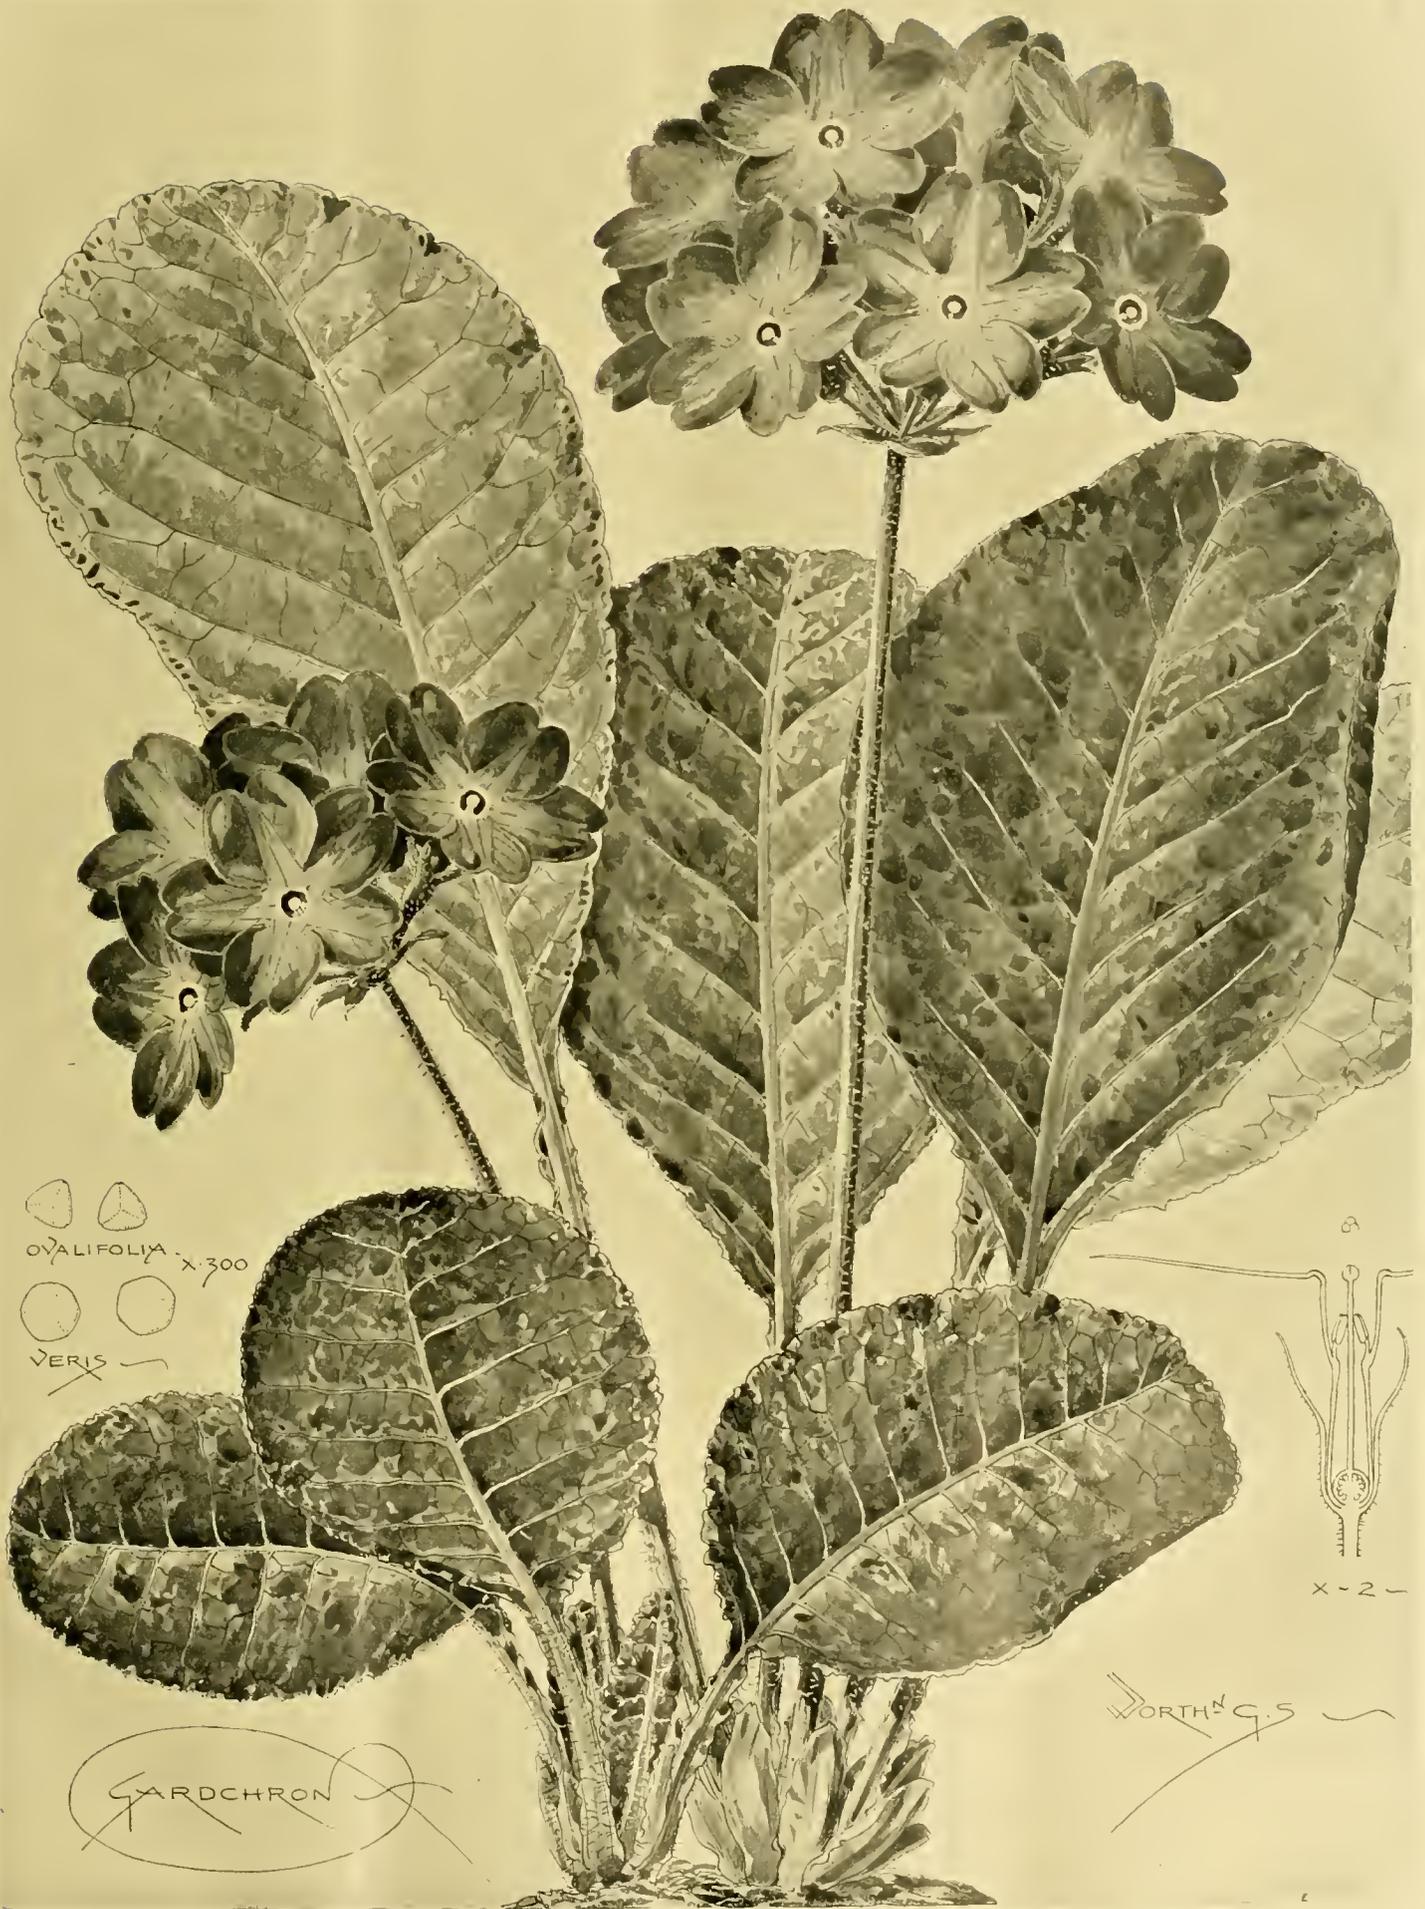

ALPINE FLORA.—Many of our plant-loving readers may be thinking of visiting the Alps at this season. A book small enough to go in the pocket, and containing a large number of coloured illustrations, has just been published by Dr. GUSTAV HEGI and Dr. DUNZIGER, of Munich, through J. F. LEHMANN, of Munich (WILLIAMS & NORGATE). It comprises the most conspicuous plants of Switzerland, Bavaria, and Tyrol. The text is in German, but the plates appeal to wanderers of any nationality.

MR. R. DEAN.—A number of the members of the National Chrysanthemum Society presented their Secretary with a substantial cheque at their meeting on Wednesday last. Great sympathy was expressed with Mr. DEAN in his illness.

SOUTH-EASTERN AGRICULTURAL COLLEGE.—The Archbishop of CANTERBURY visited, on Wednesday, July 19, the South-eastern Agricultural College at Wye, Kent. After service in the parish church, His Grace was entertained at luncheon in the College refectory by the Principal (Mr. M. J. R. DUNSTAN), and gave a short address to the students. A speech was also made by Mr. ALFRED AUSTIN, the Poet Laureate.

THE VEGETABLE GARDEN.—Mr. JOHN MURRAY has published a new edition of the English translation of the famous book, *Les Plantes Potagères*, issued by Messrs. VILMORIN, ANDRIEU ET CIE. It will be remembered that the authorship of the original work was in large measure due to the late HENRY DE VILMORIN. He had special opportunities and special capabilities for the task. Mr. ROBINSON rendered his countrymen good service by bringing out an English version, showing the principal types with their French representatives. As to British varieties the list is not so complete as it might be. Those interested in Potatos, for instance, will look in vain for any mention of several of the leading kinds. These were, of course, not included in the original work, but their absence from the newly published English edition is to be regretted.

CARNATIONS, PICOTEES AND PINKS.—Mr. H. W. WEGUELIN has opportunely brought out a second and revised edition of his book bearing the above title. It is published by Messrs. COLLINGRIDGE, 148, Aldersgate Street. The fact that this work has arrived at a second edition is a sufficient indication of its merits. All that we need say is that it deals with the different sections of the species *Dianthus Caryophyllus*, explains their peculiarities, details the method of cultivation suitable for each, shows in what way they may be propagated and reproduced, and in fact conveys just the information which the beginner needs. The change in public fashion is shown by the popularity of the self-coloured forms and the relegation to the florists of the old school, of whom few are now left, of the flakes and bizarres, which although interesting are not so effective in the borders or so attractive as cut flowers as are the self-coloured varieties. The Malmaison Carnations, in spite of their size, their want of refinement, and the relative difficulty of their cultivation are in high favour. The source whence this section was derived is not stated. We are glad to see the author expressing his disapproval of the childish practice of "dressing," and also of that "monstrosity" the paper collar. The illustration of a scarlet flake on p. 83 well shows the throttled appearance that flowers provided with such an appendage have. Difference of opinion upon such matters as these may still be expected till the Carnation Society discourages the practice, if not directly, at least by encouraging more natural procedures. On one

PRIMULA OVALIFOLIA—A CHINESE SPECIES, SHOWING SECTION OF FLOWER AND POLLEN-GRAINS X 300 DIAM.

point all honest men will agree, and that is that the practice which is said to exist among a certain class of exhibitors, of showing flowers which have not been grown by themselves, should meet with stern reprobation. There may be exceptional cases where, in order to make up a group or for some special purpose, it may be allowable to ignore the rule that the flowers exhibited should have been grown by the exhibitor, but in such instances the fact should be expressly stated, and no competition allowed where the conditions are not equal.

FLOWERS AND FRUITS IN SEASON.—Flowers of *Azara microphylla* are frequently seen, but fruits are much less common. Messrs. ROBERT VEITCH & SON, of Exeter, sent us a specimen bearing numerous orange-coloured berries, each about the size of the head of a large pin. Messrs. ROBERT VEITCH & SON also sent us ripe fruits of *Lucretia* Blackberry on July 17. They state that the fruits ripen quite three weeks in advance of ordinary Blackberries. It is very prolific, some of the sprays bearing eight to ten fruits.

"CLAY'S SUCCESSFUL GARDENING."—A third edition of this little handbook of practical horticulture has been issued (CLAY & SON, Stratford). Although published in the interest of a firm of manure manufacturers, it is something more than a mere trade list, as it contains articles on various departments of gardening by several experts of acknowledged position. It seems to have been as difficult to exclude "Clay's Fertiliser" from these articles as it was to keep CHARLES THE FIRST's head out of Mr. DICKS' memorial. At the end of the book is a statement as to the nature and composition of the fertiliser, which affords a proof that the good opinion held as to the virtues of this manure are justified.

MR. J. F. WILKE, the Curator of the gardens of the Zoological Society at Rotterdam has just completed twenty-five years of service in that establishment. We have had to refer to his labours on various occasions and congratulate him on having secured the approval of his employers and the respect and goodwill of his associates. Mr. WILKE is an old Kewite, and is well known to many in this country.

"THE SCOTTISH GARDENER AND NORTHERN HORTICULTURIST."—This is a newcomer, published monthly at a cost of 2d. It has only now come to our notice (the first number is dated June), or we should have welcomed it earlier. It is intended alike for professionals and for amateurs. We note among its contributors Mr. ARNOTT, Mr. LINDSAT, Mr. WOODROW, Mr. WHITTON, and others who do not hail "from Fleet Street," and who we are proud to number among our own collaborators; we are therefore in a position to congratulate our Scottish friends on the possession of a journal of their very own. We trust that its contents may be as valuable as those of its predecessor under a similar name. Doubtless we shall soon have to announce its publication as a weekly journal. The office of the *Scottish Gardener* is at 34, Robertson Street, Glasgow.

HENRY ECKFORD TESTIMONIAL.—The contributions to this fund up to the evening of Saturday, July 15, amounted to 913 shillings.

THE SALE OF POISONS.—In the House of Commons, on the 13th inst., Mr. ALEXANDER CROSS, M.P., asked the President of the Board of Agriculture when he proposes to introduce his Bill dealing with the sale of substances used extensively and in large quantity in horticulture and agriculture, but which are technically included as poisons under the schedules of the Pharmacy Act, in view of the efforts made to monopolise the trade in such articles by retail

druggists, to the injury of these industries of farming and gardening; and in reply he received the following answer:—"The Bill in question falls within the province of the Privy Council rather than my own, but I am in communication with my noble friend the Lord President as to the advisability of its introduction at no distant date, and, further, that the Bill is in a state of preparedness."

DUST NUISANCE.—Messrs. HOPE & SONS write:—"After considerable experience with our Asphalte Westrumite we now find that two barrels of it mixed with an equal quantity of water will cover 800 yards square, or a length of road 100 yards long by 8 yards wide, and would keep down the dust for many weeks. As you well know, the dust nuisance is an infliction to many a country house that has its gardens, containing either flowers or fruit, abutting on a road, and worse still, as is often the case with country houses, that front right on the highway."

NORTH LONDON NURSERYMEN held their annual outing on Thursday, 13th inst., when a visit was paid to Epping. Cricket was indulged in by the members, the teams being selected by Mr. FRANK ROCHFORD and by Mr. ALFRED WARD. One party drove round the Forest, another enjoyed themselves at quoits, &c.

FIG. 26.—THE PINE SAWFLY.
(See p. 72.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

SOME GOOD CARNATIONS.—Among the many pink forms of *Souvenir de la Malmaison* Carnation there are few that surpass the variety *Duchess of Westminster*, which is of dwarf, robust habit, and produces handsome compact flowers of a beautiful rose-pink colour, with a delicious clove scent. It has in addition a most perfectly formed calyx, one of its best points. The new yellow *Malmaison* "*Yaller Gal*" is a welcome addition among Carnations. The growth is strong and vigorous, while the flower, borne on a dwarf erect stem, is of large size and of true *Malmaison* form. The colour of the flower is a beautiful pale yellow. Absence of perfume somewhat detracts from its value. *Cecilia* forms an excellent companion to *Yaller Gal*; although not a "*Malmaison*," produces splendid blooms that are over 6 inches in diameter and of sulphur-yellow colour. *Miss Audrey Campbell* is a yellow border variety similar to *Cecilia*, except that the flowers are of smaller size. The plant is well adapted for pot culture, two-year-old plants yielding a quantity of fine flowers. *Trojan*, a pure white variety of the same type as the last-named, is equally good. *Nell Gwynne* still holds the lead as the best white *Malmaison*. Of the

crimson kinds, *Maggie Hodgson* is good. Prime Minister is one of the best scarlet varieties, and forms an excellent variety for growing as large specimen plants. The same may be said of *Sault*, the flowers of which are of a delicate salmon colour. Another worthy of notice is *Calypso*, a fine strong variety with flesh-coloured flowers, the centre petals of which are splashed with bright pink. *Gemma* and *Baldwin* are two good bright rose-pink kinds worthy of notice. *J. Murray, Sopley, Christchurch.*

EXHIBITING CARNATIONS.—Those who delight in seeing flowers, florist's or otherwise, exhibited in a natural manner, and who for years have complained of the paper collar with which Carnations are defaced, have now just cause for a fresh outcry against the unparalleled distortion of the flower, caused by the abundant use of flexible lead wire. This was all too evident on Tuesday last in some of the competitive groups of Carnations staged in pots in the Royal Horticultural Hall, Vincent Square. I am not acquainted with the rules of the National Carnation and Picotee Society, but I should very much question if this method of bending down, doubling back, and eventually endeavouring to make three or four flowers face in one direction at the top of a nearly 3 feet stake, could by any stretch of imagination be regarded as an improvement. To the visitor the contorted lead wire was far too prominent; it was abundant and all too visible on all sides of several large groups, and, in the interests of the flower it throttled to such perfection, the wire should be seen no more. Happily, there were many exhibits of Carnations in the same building where the flowers could be seen in a more or less natural manner: so that one turned away from groups where little remained of the natural grace or beauty of a flower which has been long prized in this country. Not all the competitive groups of plants were thus treated, a fact we noted with pleasure. *E. H. Jenkins, Hampton Hill.*

A LOYAL PLANT.—Some loyal colonists in the Transvaal at the present time adorn the outside of their abodes with a climbing species of *Ipomoea* (probably *rubro-cœrulea*, see *Botanical Magazine*, 3297), as it displays the national colours of red, white, and blue. From seeds sent home the plant is now daily in flower under glass in this city. Its solitary leaves are green, soft to the touch, and heart-shaped, bearing stalks on their axils carrying two or three flowers. By 3 A.M. the elegantly-folded elongated buds are already half-open. The flower resembles that of our climbing *Convolvulus*. The corolla is not, however, of the familiar white or pink colour, but is of a brilliant blue with five central bands of dullish red, and a white centre forming the tube of the corolla. Gradually the central bands intermingle with the surrounding blue and become more distinctly red, while the blue changes to mauve, and incurving of the corolla visible to the naked eye sets in. As the incurving proceeds, say from 12 to 2 P.M., complete dispersion of the red-coloured bands takes place, and a uniform pink colour is found in the outer portion of the corolla. Thus by 4 P.M. the corolla is seen to consist of its white tube with a crown of pink. The corolla thus altered may persist for more or less of the day following. The incurving ceases when the pistil and upper stamens are reached. *Observer, St. Andrews, July 5, 1905.*

GERMINATION OF SEEDS.—In reply to "T. R. P.'s" enquiry on p. 60, I may say that some of the seeds enumerated may remain dormant for a considerable time, but under favourable conditions they should have germinated before now. *Clivias* usually start very soon after they are sown. *Begonia Rex* should germinate in a few days, and there will be no chance of this growing now. *Nephrolepis exaltata* should start within a week or so after being sown. *Palm-seeds* vary considerably. I have known *Kentia* seeds to begin to grow six months after being sown, but I have always found *Livistona chinensis* to start very soon, and seeds of *Phoenix* usually do so. The seeds of *Arum* usually germinate within a week. It would seem that there must be something wrong in the treatment that has been afforded the seeds. It may be that there is something in

the soil that has caused the seeds to damp-off, or insects may have eaten them. It is remarkable that such a variety of subjects should have all failed. "T. R. P." does not say if he has raised any seeds under the same conditions as those which have failed. If the soil gets too dry after the seeds have begun to swell, it will cause failure. Over-watering, too, may cause them to rot off before they get through the soil. The Palm-seeds might be taken out of the soil, washed, and resown. It may be that the seeds have been buried too deeply. *H.*

THE RECENT CHELSEA HOSPITAL SHOW.—The Gardening Press is, as a rule, very complimentary towards the London flower shows, but sometimes seems to be too much so. That was, I think, somewhat the case with the recent Chelsea Show. Certainly it was a great show in the sense that it was big [“pretty” was our expression], but it was terribly formal, and in a great number of exhibits exceedingly commonplace. It was at the best a third-rate copy of the Temple Show. It is a fair question to ask, Is such a show needed? The attendance on the part of both Fellows and public was so poor, relative to what is seen at the Temple, that one wonders whether the lack of attendance was not due to indifference to the show; certainly some members of the trade, which do so much to make London shows, were intensely disappointed at the poor attendance and the lack of return for all their outlay. Nevertheless the Chelsea Gardens offer a far better site for a show than the Temple Gardens, as there is ample elbow-room for everyone. *A Fellow.*

LARGE STRAWBERRIES AND NEW RED CURRANTS.—Kindly allow me to correct a printer's error as given in my last letter. The name of the Strawberry is Gloire du Mans, not Maris. Also I forgot to mention that this grand fruit is derived from a cross between the varieties Sharpless and Noble. As regards the somewhat new Red Currants “Comet” and “Star of the North,” both are excellent in their way. The first is a strong grower, with dark-green, leathery leaves, and bears long, large bunches of fruit, very bright, and deep-red in colour, of good flavour and great size. No. 2 is a prolific bearer of long racemes of berries, which are sweet and luscious, but of moderate size. It is not so worthy of attention as Comet, nor of a like noble appearance, though it is about one fortnight earlier in ripening. Comet is an acquisition that not only merits but will find favour. *Harrison Weir, Kent.*

CAMPANULA TURBINATA “ISABEL.”—This excellent plant was exhibited in considerable quantity by Mr. M. Prichard at the Royal Horticultural Society's meeting on the 18th inst. The primary characters of *C. carpatica* or its variety *turbinata* are absent in the variety Isabel, which partakes of the more widely opened, shallow, saucer-like blossoms of *C. c. pelviformis*, and indeed it would appear to be a deeply-coloured and large-flowered form of this distinct variety. The flowers are coloured deep violet, and in the mass as a bedding plant, for which its profusion of flowers admirably adapts it, the variety would be most effective. The plant is about 1 foot in height, the handsome blossoms 1½ inch or more across, so that its decorative value can be gauged with some accuracy. The variety originated as a seedling in Mr. Prichard's nursery from seed-heads taken from *Campanula carpatica* Riverslea, I believe. In any case, the plant is of undoubted merit, and quite worth the attention of gardeners and amateurs. *E. H. Jenkins.*

THE PINE SAWFLY IN NORTH WALES (see fig. 26, p. 71).—It may serve a useful purpose to call the attention of foresters and nurserymen to the fact that this very destructive insect has put in an appearance in South Carnarvonshire. As the larvæ are gregarious, the colonies sometimes numbering upwards of a hundred individuals, and as they usually consume practically the whole of the leaves, they are readily detected. The following description of the caterpillars, abridged from Miss Ormerod's “Manual,” will enable anyone to

identify them:—“They have a pair of claw-like feet on each of the three segments immediately behind the head, the next segment is footless; the succeeding seven segments have each a pair of sucker-feet, and the tail is furnished with a pair. . . . The colour varies much with age, health, and weather. . . . When full-grown it has a rusty-brown head, dark forehead, and black jaws and eyes; it has an interrupted black line along each side, formed of a patch of black dots on each segment; the true feet are black; the sucker-feet are yellow, and a black line at the base; when full grown it is about an inch long.” As remedial measures, crushing with a gloved hand is recommended, or they may be shaken from the trees on to cloths spread on the ground. A useful leaflet (No. 103) concerning the pest has been issued by the Board of Agriculture; copies may be obtained, gratis and post free, on application to the Board, 4, Whitehall Place, W.C. *C. W. Herbert Greaves, Pullheli.*

FLOWER-SHOW ENUMERATORS.—The unfortunate disqualifications which occurred at the recent Sweet Pea Show help to emphasise the

“twenty sprays shall form a bunch. The vase with only eleven sprays ought certainly to have been disqualified, and the collection also which your correspondent says averaged sixteen or seventeen flowers in a vase. I fully sympathise with the judges and secretary. These occurrences are most unpleasant to all, but it is best to set a correct standard and adhere rigorously to it. Justice and fair play always win in the end. *W. H. Divers, Belvoir Castle Gardens.*”

THE POTATO DISEASE.—The first evidence of the presence of the too well-known *Phytophthora infestans* amongst our Potato crops this year that has come under my notice, and so far happily the only one, was seen in a small cottage garden in Surrey recently. I refer to it specially because it illustrates so forcibly all that the Editor has from time to time urged as to the necessity for the destruction of diseased haulm. Close behind an Ivy-covered outhouse was a festering heap of garden refuse, much of it evidently having lain there from last year. Adjoining it was a patch of Potatoes, and it was evident the disease-spots had started from close to the refuse-heap. The

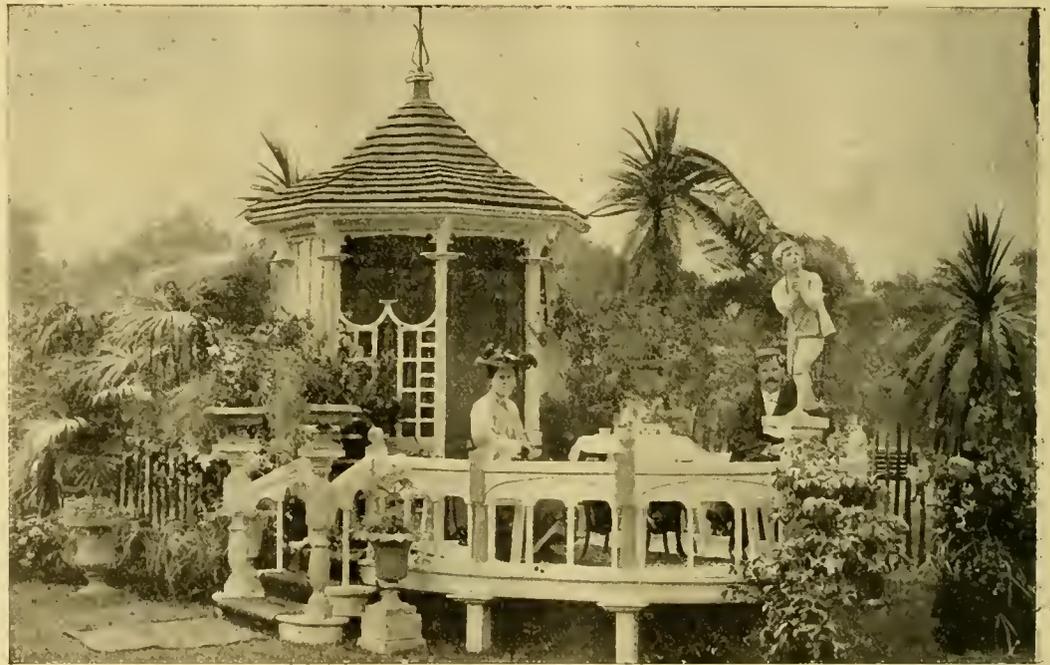

FIG. 27.—THE NEW “ALEXANDRA” TEA OR SUMMER-HOUSE.

Exhibited by Messrs. W. Wood & Son, Ltd., at the Royal Horticultural Show at Chelsea. See last week's issue. (Photo by J. Gregory.)

need there is at so many shows for the appointment by committees of enumerators of exhibits independently of judges. What could be more absurd at the Sweet Pea Show than to bring men like Messrs. Molyneux, Foster, and Burpee together to judge of the merits of the various bunches of Sweet Peas put before them, and then to compel them to count the numbers in scores of the bunches as a preliminary to making awards? If the Committee choose to set up arbitrary conditions as to numbers, let the Committee appoint some from their own body to see that those conditions are carried out. Judges, except in any case of glaring impropriety, should consider that exhibits staged under the eye and authority of the Committee are according to schedule, and proceed to deal with them on their merits. A wise enumerator would rather see an error corrected than hastily disqualify an exhibit. *D.*

JUDGING AT THE SWEET PEA SHOW.—In accordance with the regulation as to numbers, quoted from the schedule on p. 51, the judges were quite right in disqualifying those exhibitors who staged more than the stipulated number of sprays. To say that any man of average intellect cannot count correctly up to twenty is absurd. The fault appears to have been that the judges did not also disqualify those with fewer than twenty sprays, as they were evidently “not according to the schedule,” which expressly states that

patch was as badly diseased, the leaves being blackened with fungoid spots, as may be usually seen on plots a month later. Out of practically thousands of Potato-patches, I had not seen a disease-spot elsewhere. Here were enough to infect the entire parish, and as the muck-heap was left to fester instead of being burned it was the cause of the infection. *A. D.*

TWO NEW CARNATIONS.

In this issue we give illustrations at figs. 23 and 28, pp. 65 and 73, of two new varieties of Carnation that have been shown by Mr. Jas. Douglas, Edenside Nurseries, Great Bookham. The first of these varieties, named Bob Acres (see fig. 23), was given an Award of Merit at the Royal Horticultural Show, in the Vincent Square Hall on July 4. It is a border variety having rich scarlet-coloured flowers 2 inches or more across, of excellent form, and possessing considerable fragrance.

“Miss Willmott” is shown at fig. 28, and was greatly admired at the Royal Horticultural Society's show at Chelsea. Like Bob Acres this variety is suitable for cultivation in the border. The flowers are of a shade of colour we may describe as cherry-red, they are three inches and a half in diameter, and of excellent form, with smooth petals of unbroken outline.

SOCIETIES.

THE ROYAL HORTICULTURAL.

JULY 18.—On the occasion of the fortnightly meeting of the Committees on Tuesday last, the annual show of the National Carnation and Picotee Society was held in the Hall, at Vincent Square, Westminster. In consequence there were fewer groups of Orchids and other plants for inspection by the Committees than usual.

The ORCHID COMMITTEE recommended four Awards of Merit to novelties; and the FLORAL COMMITTEE recommended eleven Awards of Merit.

No novelty was certificated by the FRUIT AND VEGETABLE COMMITTEE at this meeting.

In the afternoon a lecture on "The Wisley Gardens" was given by Mr. S. T. WRIGHT, and was illustrated by lantern-slides.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. H. B. May, Geo. Nicholson, Jas. Walker, Jno. Green, C. J. Salter, J. T. Bennett-Poe, Geo. Paul, R. Hooper Pearson, Harry Turner, Chas. Dixon, H. J. Jones, W. Cuthbertson, W. P. Thomson, E. H. Jenkins, M. J. James, H. J. Cuthush, E. T. Cook, Geo. Gordon, R. M. Wallace, J. F. McLeod, and Jno. Jennings.

A very praiseworthy group of flowers of hardy herbaceous plants came from Lady HARMSWORTH'S garden at Guildford (gr., Mr. Goatley). There were fine bunches of excellent Phloxes, such as Coquelicot and Le Siècle; Pentstemons of the large-flowered type; the old *Monarda didyma*, *Lychnis chalconica*, *Lilium Henryi*, also a few shrubby plants such as *Ceanothus Gloire de Versailles*, *Roses*, &c. (Silver-gilt Flora Medal).

Lady PHILLIMORE, Cam House, Campden Hill, W. (gr., Mr. Becht), showed an extensive group of single-flowered Hollyhocks, cut off at a point near to the ground. There were named varieties having yellow, rose, red, purple, and white-coloured flowers. The plants having been grown within two miles of Charing Cross, their qualities could hardly be expected to be of the best (Silver Banksian Medal).

Messrs. R. WALLACE & Co., Kilmfield Nurseries, Colchester, showed a collection of hardy flowers, having a selection of many of the best things now in season.

Messrs. BARR & SONS, King Street, Covent Garden, also showed some excellent examples of hardy flowers.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, exhibited a very showy group of hardy flowers, in which the herbaceous Phloxes and other species in season were represented.

The Misses HOPKINS, Mere, Knutsford, Cheshire, staged Gaillardias and other showy border flowers.

Mr. M. PRICHARD, Christchurch, Hants, exhibited a collection of border flowers, in which the most beautiful and striking feature was a group of the deeply-purple-coloured variety of *Campanula* "Isabel" (see note on p. 72). The *Pyrethrums*, *Heleniums*, *Gaillardias*, *Astilbes*, *Corcopsis*, &c., were all finely grown specimens (Silver-gilt Banksian Medal).

Mr. J. F. McLEOD, Dover House Gardens, Roehampton, exhibited some finely-coloured plants of a good seedling variety of *Codiaeum* named Florence. It is a narrow-leaved form, coloured yellow and green.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, staged a group of *Codiaeums* (*Crotons*) similar to that displayed by him at the recent flower show at Chelsea (Silver Flora Medal).

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield, exhibited cut Carnations, showing a large number of varieties (sixty-one) of the "tree" and "border" types (Silver Banksian Medal).

Messrs. PHILLIPS & TAYLOR, Lily Hill Nurseries, Bracknell, Berks, exhibited Carnations in pots, having about thirty plants in as many varieties.

Messrs. THOS. WARE, Ltd., Feltham, Middlesex, contributed a well-arranged exhibit of Carnations. The flowers were shown in a light and graceful manner. An epergne containing the white Everlasting Pea, *Lathyrus latifolius albus* "White Pearl," occupied the centre of the group (Silver Banksian Medal).

Mr. J. DOUGLAS, Edenside Nurseries, Great Bookham, showed a collection of very choice Carnations. Two of the best varieties that had not been previously exhibited are described under "Awards" (Silver Banksian Medal).

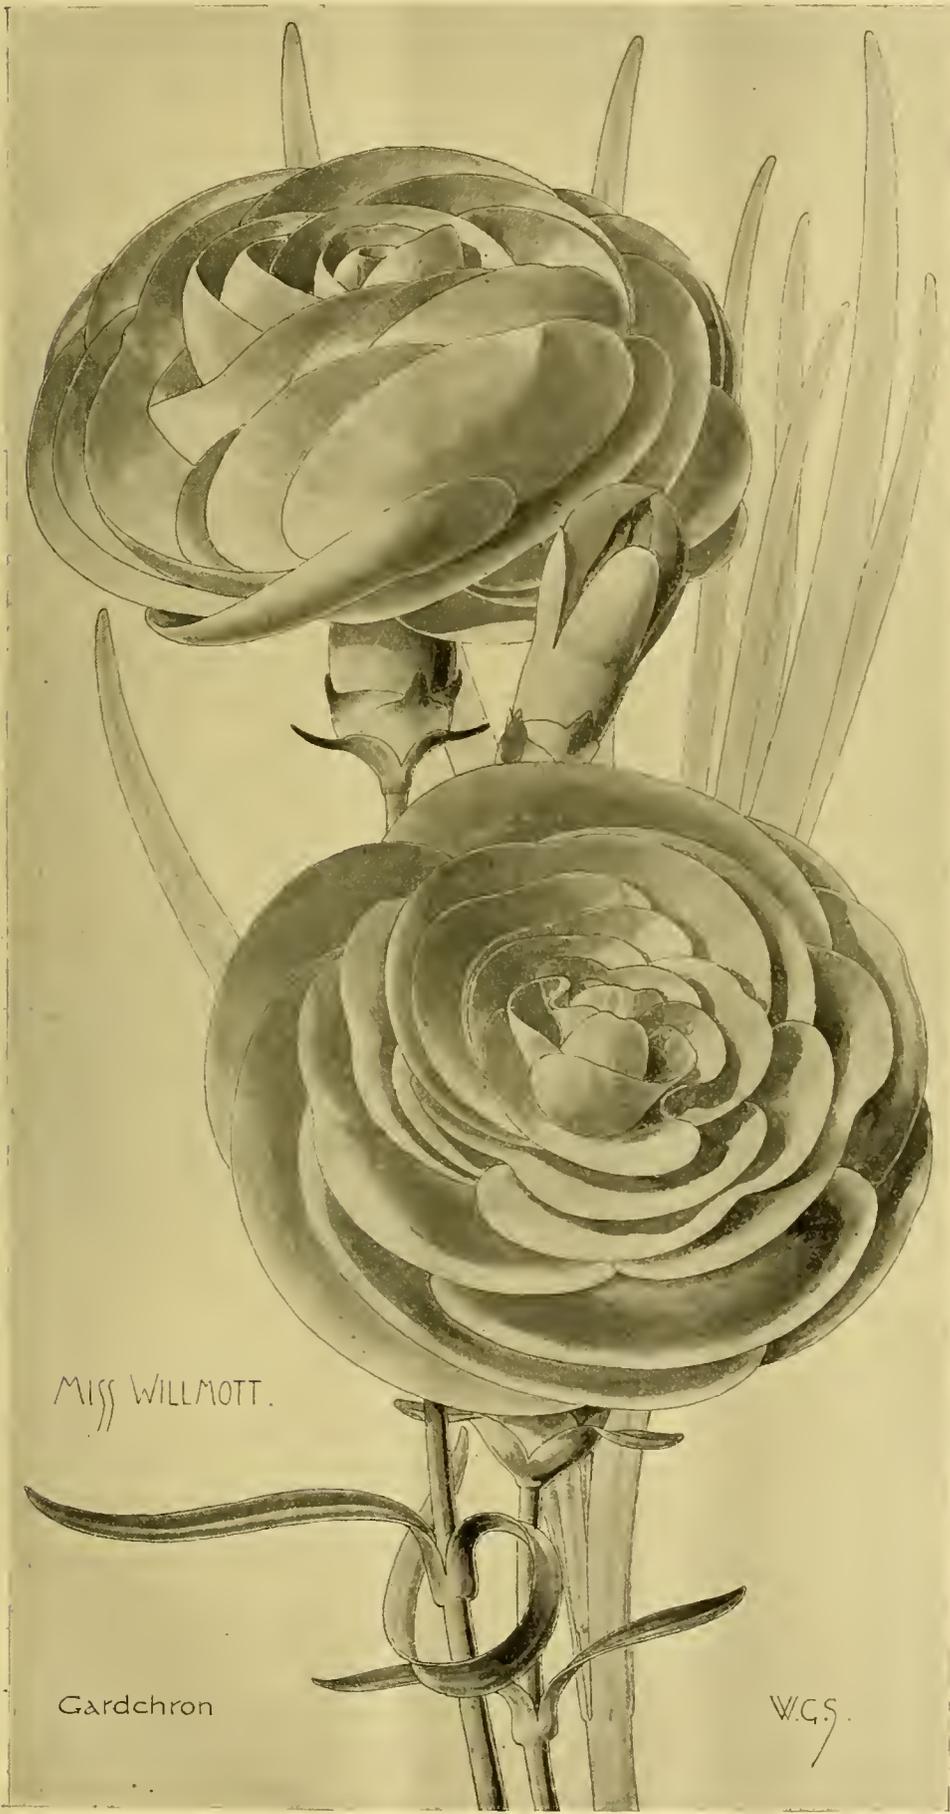

FIG. 28.—CARNATION MISS WILLMOTT: COLOUR CHERRY-RED.

(SEE P. 72.)

Gardchron

W.C.S.

Messrs. CUTBUSH & SONS, Highgate, London, N., showed some excellent Carnations, among which was a fine assortment of "Malmansons." Tree and border varieties were also represented, and the whole was staged with artistic effect (Silver Flora Medal).

Messrs. JOHN PEED & SON, West Norwood, London, S.E., staged a batch of "Tree" Carnations, with Acers, Ferns, &c., for relief; the white variety Hildegarde was shown well.

Messrs. BLACKMORE & LANGDON, Twerton Hill Nurseries, Bath, showed some well-grown flowers of Carnations, using Bamboo stands and vases for their display.

Mr. A. F. DUTTON, Iver, Bucks, showed a splendid batch of Carnations, chiefly of the American type of flower (Silver-gilt Banksian Medal).

Messrs. JAS. VEITCH & SONS, Ltd., King's Road, Chelsea, set up a most interesting group of plants, among which were several new Chinese plants. The more noteworthy was a white Astilbe (see Awards), *Lilium Sutchuenense*, and *Sencio Ligularia var. speciosa* (see Awards). The collection also embraced such fine plants as *Buddleia variabilis* Veitchiana, *Astilbe Davidii*, *Lilium Bakerianum* (showing forms of this variable species, see fig. 29, p. 75), *Vitis Thomsoni*, *V. armata*, and *Actinidia chinensis*. *Clethra canescens* was shown well, as was also *Amorpha canescens*. *Cornus macrophylla* is a tree 20 feet or more in height; it forms a handsome subject when covered with its numerous umbels of white flowers. Messrs. VEITCH also showed small pot plants of *Solanum Wendlandi*, each carrying excellent trusses of flowers; a batch of the beautiful *Exacum macranthum*, whose flowers are of the loveliest shade of deep blue; *Allamanda grandiflora*, and a representative collection of tree and border Carnations (Silver-gilt Flora Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, staged an extensive group of Gloxinias, small plants in 48's, but well flowered, and representing most of the best named varieties of these showy flowers. Plants of *Kochia scoparia* were used as a background to the Gloxinias. Messrs. CANNELL also showed a selection of very well grown Shirley Poppies, and a distinct coloured Antirrhinum called Defiance. The colour may be described as orange-scarlet (Silver Banksian Medal).

G. FERGUSON, Esq., The Hollies, Weybridge (gr., Mr. Smith), staged a group of *Campanula Fergusoni*, a hybrid form resembling *Campanula turbinata*. The group was very prettily arranged, Ferns, Bamboos, Asparagus, and such-like plants being freely intermixed with the *Campanulas* (Silver Flora Medal).

Mr. H. CRANE, Woodview Terrace, Highgate, showed a number of small-flowering *Violas* arranged in the form of sprays (Bronze Banksian Medal).

Messrs. W. & J. BROWN, Stamford and Peterborough, exhibited flowers of the climbing *Roses* Lady Gay and Dorothy Perkins; also cut *Roses* of other varieties, and flowers of the "Cactus"-like *Pelargoniums*.

Linaria vulgaris Peloria. Flowers of this interesting plant were shown by Mr. WILLIAM MARSHALL, Chairman of the Floral Committee.

Awards.

AWARDS OF MERIT.

Adiantum Mayii.—This is described as a seedling from *A. fragrantissimum*. The plant is remarkable for its long pinnules and the delicate tracery in the fronds. It is a very elegant variety. Shown by Mr. H. B. MAY.

Astilbe grandis.—The plants of this Chinese species were 7 feet or more high, and had compound ternately pinnated leaves, and inflorescences some 4 feet long, bearing white *Spiraea*-like flowers. From Messrs. JAS. VEITCH & SONS.

Carnation Liberty.—This is a fancy border variety. The flowers are of large size, and full in the centre. In colour they have a yellow ground heavily striped with crimson. Shown by Mr. JAS. DOUGLAS.

Carnation Viscountess Ebrington.—This is a first-class self-coloured variety, being of very pale buff. The flowers are of satisfactory form and size. Shown by Mr. JAS. DOUGLAS.

Lilium Sutchuenense.—This Chinese species has very narrow lanceolate leaves, from 3 to 3½ inches long, and deep orange-red coloured flowers, like those of *L. tigrinum*. The petals are very much recurved, and thickly spotted with blackish-brown spots. Some of the growths had six flowers on each, but others had fewer. It is a comparatively small, elegant species of considerable refinement, having a pretty effect as

grown in pots. Shown by Messrs. JAS. VEITCH & SONS.

Phlox "Dorcen". A pink-coloured variety of herbaceous *Phlox*, with a ring of reddish-rose colour round the centre of each flower. The flowers are of regular form, and individually measure 1½ inch across. Shown by J. BRADSHAW, Esq. (gr., Mr. Whitelegge).

Sencio Ligularia var. speciosa.—This is one of the largest-growing Groundsels from Central China. Its great green leaves and immense spikes of yellow flowers will make the species valuable for planting in the "bog" or "wild" garden. Shown by Messrs. JAS. VEITCH & SONS.

Violas, Councillor Watters (DOBBIE & Co.), a purple-coloured variety; Mr. McFarlane (DOBBIE & Co.), purple and blue-coloured, of the "Magpie" type; Isalde (DOBBIE & Co.), pale yellow, rayless; and Stark's Royal Sovereign (STARK), very deep, rich yellow, rayless. All these varieties have been cultivated at Wisley, and were selected from a large number growing there by a deputation from the Floral Committee, which visited Wisley for this purpose on Monday last.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Secretary), De B. Crawshaw, W. A. Bilney, H. Little, W. Cobb, W. Boxall, F. W. Ashton, G. F. Moore, H. T. Pitt, W. H. Young, and R. Brooman-White.

There were no groups staged, the exhibits being confined to those intended to go before the Committee for Awards.

AWARDS OF MERIT.

Laelio-Cattleya × chardwarensis (L. cinnabarina × C. dolosa), from G. F. MOORE, Esq., Chardwar, Bourton-on-the-Water (gr., Mr. Page). A very pretty and delicately-tinted flower. The plant bore an inflorescence of eight flowers, arranged bouquet-like on a stem 9 inches long. Flowers 3½ inches across. Sepals and petals lanceolate, the petals broader than the sepals, both blush-white with a rose tint in some stages of the flower and a buff hue in others. Lip three-lobed, the side-lobes turned back at the tip, middle lobe ovate; both pale yellow beautifully veined with rose-purple.

Miltonia verrillaria radiata magnifica [], from Mrs. HAYWOOD, Woodhatch, Reigate (gr., Mr. C. J. Salter).—A very distinct variety, with large rosy-lilac flowers, the labellum having a large white disc, on which were numerous claret-purple lines radiating from the base and some shorter dotted lines between (Botanical Certificate).

Maxillaria picta Warley variety, from Miss E. WILLIOTT, Warley Place, Great Warley, Essex (gr., Mr. Preece).—It differs from the type in its broader segments and the character of the markings.

Notylia multiflora, from Messrs. HUGH LOW & Co., Enfield.—A singular species with ovate leaves and long pendulous racemes of small green-and-white flowers.

C. J. LUCAS, Esq., Warnham Court, Horsham (gr., Mr. Duncan), sent *Laelio-Cattleya × Geoffrey* (*Laelia longipes* Lucasiana × *Cattleya Warszewiczii*), a very pretty hybrid preserving the shape of the yellow-lipped form of *L. longipes*, known as *L. Lucasiana*, but with the segments nearly as broad as *L. pumila*. Sepals and petals light rose coloured; lip much crimped, rose-coloured at the base and margin, the rest orange coloured.

The Rt. Hon. Sir A. B. CROSSLEY, Bt., M.P., Somerleyton Hall, Lowestoft (gr., Mr. Hanson), sent a fine flower of *Laelio-Cattleya × Olive* (*L. pumila* prestans × *C. Dowiana aurea*).

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. Davis), sent *Laelio-Cattleya × Hy*. Greenwood Glebelands variety), a dwarf, large-flowered variety with white sepals and petals delicately tinged with lilac, and a fine purple front to the labellum. Also *Cypripedium × Penelope* (*Morganie × superbians*).

Messrs. JAS. VEITCH & SONS, Chelsea, showed *Cattleya × Carmen* (*Warszewiczii × Luddeimanniana*), a fragrant flower of a light rose colour with ruby-purple front to the lip.

Messrs. HUGH LOW & Co. sent *Phalenopsis violacea* Low's variety (a very fine form).

Fruit Committee.

Present: Geo. Bunyard, Esq., in the Chair; and Messrs. Jos. Cheal, W. Bates, S. Mortimer, A. Dean, H. J. Wright, Jno. Basham, Geo. Kelf, J. Lync, F. Q. Lane, Geo. Reynolds, J. Willard, J. Jacques, C. Foster, Owen Thomas, J. McIndoe, and A. H. Pearson.

Messrs. JAS. CARTER & Co., 237, High Holborn, London, showed a collection of 125 distinct varieties of culinary Peas. All the varieties were sown on March 30, and the exhibit was interesting in showing the fruiting period of the various varieties (Silver Banksian Medal).

Messrs. JOHN K. KING & SONS, Coggeshall, Essex, showed a similar but somewhat smaller collection of culinary Peas. They were selected from a trial of 180 distinct varieties, and were all sown on the same day.

A box of Early Rivers' Nectarine was staged by Mrs. HAYWOOD, Woodhatch Lodge, Reigate (gr., Mr. Salter). The box contained about four dozen fruits, all of high-class finish and of great size (Silver Knightian Medal).

Mr. George NORMAN, Hatfield House Gardens, Hatfield, Herts, showed a splendid box of Brown Turkey Figs, and was deservedly awarded a Silver Banksian Medal.

Messrs. ROBT. VEITCH & SON, Royal Nurseries, Exeter, displayed a dish of bramble fruits named *Rubus Lucretia*. The variety is remarkable for its early period of fruiting. The fruit closely resembles the common Blackberry in other respects, but it is deficient in flavour.

Messrs. HOBBS, Ltd., Norfolk Nurseries, Dereham, showed a Red Currant labelled Chevalier's Sensation. It is very similar to the variety known as Comet.

Mrs. PULLINGER, Morrey Lodge, Campden Hill, W. (gr. Mr. Winfield), showed an enormous Cucumber labelled Improved Telegraph.

Lecture on "Wisley."

The afternoon lecture was given by Mr. S. T. Wright, the Superintendent of the Wisley Garden. With the aid of an excellent series of photographic illustrations, Mr. Wright succeeded in conveying a very good idea of the beauty and interest of the Society's new garden. As we alluded to the subject quite recently we need do no more than state that Mr. H. J. Veitch, who was in the Chair, reiterated the promise given by the Council, of eventually establishing a research station at Wisley, and stated that Mr. Massee had already begun some experiments, the nature of which did not transpire.

NATIONAL CARNATION AND PICOTEE.

(SOUTHERN SECTION.)

JULY 18.—This Society held its annual exhibition on the above date in the Royal Horticultural Hall, Vincent Square, Westminster. So far as we could judge, the exhibits were about equal in number to those staged last year, the entries being 452; and in regard to the quality of the flowers, it may be said that some of the specimens were excellent. The President of the Society, Martin R. Smith, Esq., was successful in many of the classes in the first division as usual, and there were four of his varieties included in the collection of nine seedlings that were awarded First-class Certificates of Merit.

The exhibition served to remind many who are not Carnation specialists of the peculiar characteristics that separate the florist's, "bizarre," "flaked," "fancy," and "self" Carnations, and of the Picotees. The self-coloured Carnations undoubtedly make the best show, but some of the Picotees, of light edges and heavy edges, are really beautiful in their markings upon close inspection. The flakes, bizarres, and "fancies" also have their admirers.

Most of the flowers were unfortunately staged with paper collars in boxes, and "dressed" to appear as perfect as possible from the florist's standpoint; but in a few instances there could be seen flowers disposed in vases relieved by Carnation foliage, where in our opinion they had a much better effect. In some of the groups of plants shown in pots the leaden wires used to support the flowers were too obtrusive.

Mr. T. E. Henwood, the Secretary, was kept busy during the whole day.

BIZARRES AND FLAKES.

The best twenty-four bizarres and flakes in not fewer than twelve dissimilar varieties were staged by Mr. F. WELLESLEY, Westfield, Woking. Form was the principal feature of this collection, every flower being shown in good condition; but the markings and colours were also good. The varieties shown were Master Fred, George Melville, Robert Lord, Meteor, Guardsman, Gordon Lewis, Robt. Houlgrave, H. Shoemith, C. J. Keen, J. S. Hedderley, Sportsman, Wm. Skirving, A. Curzon, and George. There were two other competitors—MARTIN R. SMITH, Esq., Hayes, Kent; and Mr. CHAS. TURNER, Slough, who were awarded 2nd and 3rd prizes respectively. Mr. SMITH put up some good flowers, notably Meg Merrilies, Hotspur, Lighthouse, R. Houlgrave, Challenger, and Autocrat.

In Division II., in a class for twelve "dressed" blooms distinct, there were five collections, and the 1st prize was won by Mr. R. C. CARTWRIGHT, Kings Norton, Worcestershire, who showed the varieties Gordon Lewis, W. Prescott, Admiral Curzon, Master Fred, Robert Houlgrave, W. Skirving, Geo. Melville, Guardsman, Sarah Payne, Merton, J. S. Hedderley, and Calypso. 2nd, Mr. H. R. TAYLOR (gr. Mr. Gilbert), Oakleigh, Cheam. 3rd, Mr. PEMBERTON, Bloxwich.

SELF-COLOURED FLOWERS.

Mr. WELLESLEY was also first in the class for twenty-four "selfs" having the same opponents who followed in the same order as in the previous class.

He had very fine flowers indeed, showing the varieties Ensign (white), Bridegroom (rose-pink), Seagull (salmon-pink), W. H. Parton (crimson), Borrás (cherry-red), Germain (yellow), Cassandra, Mrs. E. Hambro (white), Mrs. Guy Seabright (pink), Her Grace (white), Mrs. R. C. Cartwright (salmon-red), and Lady Hermione (salmon-rose). The 2nd prize collection from H. R. TAYLOR, Esq., Oakleigh, was also very good. 3rd, Mr. W. SPENCER, jr., Windsor.

FANCY FLOWERS.

The Class for twenty-four "fancy" flowers was also contested by the same three growers as in the preceding classes, but they had an additional rival in the firm of Messrs. BLACKMORE & LANGDON, Twerton Hill

Mr. SMITH staged the best six flowers of a yellow or buff-ground fancy Carnation, having King Solomon; but he had worthy competitors in Mr. WELLESLEY, with Westfield Seedling; and in Messrs. BLACKMORE & LANGDON, with Richness.

In Division 2, the variety Argosy, shown by Mr. F. H. A. BOOTH, won the 1st prize in a similar class for six blooms.

MESSRS. BLACKMORE & LANGDON easily carried off the 1st prize for six blooms of any variety of "fancy" Carnation other than yellow or buff-coloured grounds. The variety was Millie—excellent flowers in every respect. Mr. WELLESLEY followed 2nd with the same variety; and Mr. SMITH was placed 3rd with The Nizam.

FIG. 29.—LILIUM BAKERIANUM (LOWII),

Forms of which were shown by Messrs. James Veitch & Sons on Tuesday last at the Royal Horticultural Society's Meeting. Flowers greenish-yellow or white, purple-spotted. (See p. 74.)

The 1st and 2nd groups ran each other close for supremacy, but Mr. Wellesley's flowers had more substance and were of slightly better form. The varieties in this group were Daffodil, Gloriosa, Sir Bevy's, Benbow, Mrs. Guy Seabright, Bridegroom, Much the Miller, H. J. Cutbush, Mrs. F. W. Flight, Pink Pearl, Mrs. Eric Hambro, Comet, Nubian and Mrs. Charrington. The best flowers in the 2nd prize group were Daffodil, Mary Hambro, H. J. Cutbush, Mrs. E. Hambro and Etna.

The best six flowers of any variety of self-coloured Carnation belonged to MARTIN SMITH, Esq., who had the beautiful white variety Mrs. Eric Hambro in fine form. Scarcely less inferior were the half-dozen flowers of Mrs. F. W. Flight staged by Mr. F. WELLESLEY.

In DIVISION II. the variety Daffodil shown by Mr. R. C. CARTWRIGHT also gained 1st prize. Messrs. PHILLIPS & TAYLOR were 2nd with the variety Mrs. M. Y. Charrington.

In DIVISION II. in a class for twelve blooms, distinct, Mr. R. C. CARTWRIGHT had the 1st prize.

Nurseries, Bath. Mr. MARTIN SMITH was the successful exhibitor, and a well-grown lot of flowers were those shown by him. The Skipper, Hesperus, Cavalier, Juno, and Merlin occupied the back row, and were all of first quality; and there were in addition good flowers of Mandarin, Hidalgo, Pasquin, Mrs. Leo Hunter, Heeuba, Merlin, Molly Maguire (grand flower), Sam Weller, Andromeda, Cheops, King Solomon, Cavalier, Juno, and Robin Hood. 2nd place was awarded Mr. WELLESLEY, who showed Perseus, Professor Cooper, Monarch, Miss Leese, and Molly Maguire in fine condition. 3rd, Messrs. BLACKMORE & LANGDON.

In Division II., for twelve blooms, distinct, F. H. A. BOOTH, Esq., Hoe Place, Woking (gr. Mr. Nash), had 1st prize for twelve very pretty flowers, showing Argosy, Monarch, Foeman, Hidago, Lady Bristol, Brodriek, Oakley, Jno. Seabright, Eldorado, Professor Cooper, Amphion, and Gipsy Queen. Mr. W. SPENCER, jun., ran very closely for 2nd place; and Mr. R. C. CARTWRIGHT was 3rd. There were six exhibitors.

In DIVISION II., Mr. R. C. CARTWRIGHT obtained 1st prize with the variety Millie in a similar class for six blooms.

PICOTEES.

In the class for twenty-four Picotee flowers Messrs. BLACKMORE & LANGDON dropped out, leaving the field to the remaining three, Messrs. SMITH, WELLESLEY, and TURNER, who were placed in the order named. Mr. SMITH had some perfectly-formed flowers, possessing great refinement. The Mrs. H. Hoskier shown in his group was the best heavy-edged white-ground Picotee in the show, and the Pride of Leyton the best light-edged white-ground Picotee shown. Other beautiful examples were Brunette, Baliol, Favourite, Winston Churchill, and Amy Robsart. Mr. WELLESLEY showed a collection that ran the 1st prize group close for supremacy, having Lavinia, Little Phil, Mrs. Barron, Ganymede, Pride of Leyton, and others in first-class condition.

Mr. WELLESLEY reversed the order of position with Mr. SMITH in the class for twenty-four yellow-ground "Picotees," and certainly his collection was worthy

the position. His flowers were a remarkably fine lot, and contained the premier heavy-edged and the premier light-edged yellow-ground "Picotees" in Gronow, which secured the former distinction, and in Miss Walter Heriot, which gained the latter. To do the group justice each variety should be noted, but owing to considerations of space we select Lady St. Oswald, Gertrude, Daniel Defoe, Gronow, Lney Glitters, and Othello. Mr. SMITH had Raphael, Ida, Maria, Chryseis, &c.

Mr. WELLESLEY staged six exquisite flowers of Mrs. W. Heriot in the class for the best six yellow-ground Picotees. Mr. SMITH was 2nd with smaller but good flowers of the same variety. 3rd, Mr. C. TURNER.

In a similar class in Division II., the variety Mrs. W. Heriot was awarded 2nd and 3rd prizes.

In Division II., the best collection of twelve blooms of white-ground Picotees was shown by F. H. A. BOOTH, Esq., who had the varieties W. H. Johnson, Lavinia, Pride of Leyton, Brunette, Beswick, Fanny Tete, Favourite, Mrs. Barron, Mrs. Openshaw, Amy Robsart, G. Darling, and Nellie. 2nd, Mr. H. R. TAYLOR; and 3rd, Mr. HAYWARD MATHIAS, Hazel Parton, Medstead. There were seven exhibits.

In Division II., in a class for twelve yellow-ground varieties, there were seven collections, and of these one from Mr. W. SPENCER, Jr., won the 1st prize. The varieties Gronow, Mrs. Walter Heriot, and Epsom, were the prettiest flowers in this exhibit. 2nd, F. H. A. BOOTH, Esq.; and 3rd, Messrs. PHILLIPS & TAYLOR, Lily Hill Nurseries, Bracknell.

SINGLE BLOOM CLASSES.

The best scarlet bizarre was Robt. Houlgrave, staged by Messrs. PHILLIPS & TAYLOR, Bracknell; the best crimson bizarre was Mr. TURNER's Arline; and the premier pink bizarre, Wm. Skirving, shown by Mr. J. FARLIE, Acton. Among the "flakes" the best purple was Gordon Lewis, shown by Mr. WELLESLEY; the best scarlet, Sportsman, belonging to Mr. H. R. TAYLOR, Cheam, Surrey; while the best rose flake was shown by Mr. WELLESLEY in H. Shoemith.

In the classes for single blooms of Self Carnations the premier flowers were the following:—White or blush-white, Mr. E. CHARRINGTON's example of Mrs. Eric Hambro; rose or pink, Gay Sbright, shown by Mr. CARTWRIGHT; scarlet, red, or crimson, Mrs. Best, shown by Messrs. PHILLIPS & TAYLOR; maroon or purple, W. H. Parton, shown by Mr. W. H. PARTON, yellow, Daffodil, also shown by Mr. PARTON; buff, Mrs. Cartwright, shown by Mr. R. C. CARTWRIGHT.

Among the "fancies" the best yellow-ground variety was Westfield Seedling, shown by Mr. WELLESLEY; Mr. MARTIN SMITH taking 1st for any other fancy not of yellow ground, with the Mizam.

The best Picotees were as follows:—Reds:—The best heavy-edged was Brunette, shown by Mr. WELLESLEY, who also showed the best light-edged red in Mrs. Gorton. Purples: the premier heavy-edged was Mrs. Openshaw, belonging to Mr. H. R. TAYLOR; and the premier light-edged, Mrs. Farquhar, shown by Mr. W. SPENCER. Rose or Scarlet: Little Phil took 1st prize among heavy-edged varieties; while the same distinction was won by Fortrose for the best light-edged. They were shown by Mr. W. H. PARTON and Mr. WELLESLEY respectively. Yellow-ground, the best heavy-edged was Dalkeith, from Mr. MARTIN SMITH.

PREMIER BLOOMS.

The best specimens in the show of the various types of flowers were the following:—Bizarre R. Houlgrave, shown by Mr. WELLESLEY; flake H. Shoemith, from the same grower; self Ensign, belonging to Mr. MARTIN SMITH; fancy Brodrick, shown by Mr. BOOTH, Woking; heavy-edged white-ground Picotee Mrs. Hoskier, and light-edged white-ground Picotee Pride of Leyton, both shown by Mr. MARTIN SMITH. Mr. WELLESLEY had both the best heavy-edged yellow-ground Picotee and the best light-edged yellow-ground Picotee in Gronow and Mrs. Walter Heriot respectively.

THE PRESIDENT'S CUP.

The President of the Society, Martin R. Smith, Esq., as usual offered a cup to the winner of the highest aggregate number of points gained by any one competitor in the first division. Cups were also offered in the remaining three divisions. Mr. WELLESLEY secured the cup in the Division I., with the largest aggregate number of points; in Division II. Mr. CARTWRIGHT was successful; in Division III. Mr. FARLIE, and in Division IV. Mr. PARTON.

CARNATIONS IN VASES.

An interesting class was that for twelve distinct varieties of "sells," "fancies," and "yellow ground" Carnations, three flowers of each variety. The schedule stipulated that they be shown in vases with Carnation foliage to each. One was thus the better enabled to appreciate the beauty of these charming flowers, although perhaps the method is not so well suited for judging individual blooms. The best were shown by Mr. SMITH, who had Cecilia, Cavalier, Mandarin, The Seer, Merlin, Sunshine, Hidalgo, Thais, Molly Maguire, King Solomon, Gronow, and Juno. 2nd, Mr. WELLESLEY. 3rd, Messrs. BLACKMORE & LANGDON.

In Division II. there was a similar class for six varieties distinct. "Sells," "fancies," and "yellow grounds" were permissible, and the flowers were arranged in vases with Carnation foliage. The 1st prize collection contained the varieties Voltaire, Agnes Poirée, Richness, Bridegroom, Mrs. W. Heriot, and Perseus. All of these were very good flowers. 2nd, Messrs. PHILLIPS & TAYLOR, who had brightly coloured flowers of rather smaller size. 3rd, H. R. TAYLOR, Esq. (gr., Mr. Gilbert).

CARNATIONS FOR DECORATION.

The chief exhibits in the decorative classes were the single vases of Carnations, a superb arrangement of the variety Richness, with grasses, &c., winning the 1st prize for Messrs. BLACKMORE & LANGDON.

GROUPS OF CARNATIONS IN POTS.

Three collections were staged in the class for a group of plants to be arranged in an area of 50 square feet, but the 1st prize exhibit was far ahead of the remaining two. It was put up by Mr. Blick, gr., to MARTIN SMITH, Esq., and was excellent in every respect, the group being arranged with great skill, and containing flowers of the highest excellence, notably examples of "Malmaison" Mrs. Martin Smith at the background. Mr. H. LAKEMAN, Thornton Heath, Surrey, was 2nd.

SEEDLING VARIETIES WHICH RECEIVED CERTIFICATES.

Nine Certificates of Merit were awarded to the following varieties:—

Cheops (fancy), having a pale cream ground with an edging of purple and stripes down the petals, which were broad and well rounded.

Mrs. Hoskier (white-ground Picotee)—Pure white, with broad petals having a well-defined pink margin.

Roger Bacon (white-ground Picotee).—Rather a small flower of pure white ground, with a bright pink margin to broad petals. These three varieties were shown by MARTIN R. SMITH, Esq.

W. E. Dickson (heavy red-edge).—A perfectly formed flower of moderate size, having a deep crimson edge to the broad, clear, white petals.

H. Shoemith (rose-coloured flake).—A regular, well-formed flower, evenly flaked with rosy-pink colour on a clear white ground. These two varieties were exhibited by F. WELLESLEY, Esq.

W. H. Parton (self).—Of deep maroon or crimson colour with broad petals and pronounced perfume. From Mr. W. H. PARTON.

Pusquin (fancy).—A well-filled flower, having a yellow ground with heliotrope and pink markings. Shown by MARTIN R. SMITH, Esq.

R. A. Rowberry (fancy).—This variety has a buff-coloured ground with bright rosy-pink markings shading off down the petals; a very good bloom. Shown by W. SPENCER, jun.

Liberté.—See description on p. 75, col. A.

DIVISIONS III. AND IV.

These Divisions enabled the smaller growers to compete among themselves, the larger exhibitors in the preceding Divisions being excluded. The number of flowers in the classes do not exceed six, while those from thirty to thirty-four inclusive only call for three blooms in each class. The principal prize-winners in Division III. were Mr. FARLIE, Mr. PHILLBRICK, Mr. J. J. KEEN, Mr. J. J. SHELDON, Mr. WALKER, Mr. CHARRINGTON, and Hon. Mrs. TRELAWNEY.

WOLVERHAMPTON FLORAL FÊTE.

JULY 11, 12, 13.—The seventeenth annual Floral Fête was held in the West Park on the above dates in delightful weather. Prizes amounting to something like £800 attracted many well-known exhibitors, and the display of flowers, fruit, and vegetables, accommodated in six capacious marquees, must be chronicled as one of the most successful of summer shows ever held in Wolverhampton. Upwards of sixty entries were received in excess of those of last year, the total number being about 900; but in consequence of some of the exhibitors failing to show in all the classes in which they had entered, several table-spaces were left unfilled.

PLANTS.

The 1st prize of £25 offered for a group of plants not to exceed 350 square feet, was awarded to Messrs. J. CYPHER & SONS, Cheltenham, whose group, consisting mainly of Orchids, Lilliums, Ixoras, Codiaeums, and Palms, was arranged in a most artistic manner. Mr. W. VAUSE, Leamington, was 2nd with a group less graceful, and in which the colour-blending was not so finely executed. A special prize of a Gold Medal was awarded to Messrs. T. CRIPPS & SON, Tunbridge Wells, for a splendid collection of Japanese Acers.

Messrs. J. CYPHER & SONS also received the premier award of £15 for twelve stove and greenhouse plants, amongst which were superb examples of Bougainvillea Cypheri, Ixora Williamsi, Statice profusa, and Codiaeum mortefontaineense.

First prizes for six Orchids, six large Palms, twenty flowering and foliage plants (in pots not exceeding 8 inches), and twelve flowering and foliage plants (Orchids excluded), were also won by Messrs. J. CYPHER & SONS.

For six distinct varieties of exotic Ferns, J. A. KENRICK, Esq., Edgbaston (gr., Mr. A. Cryer), was an easy 1st.

For a group of one class of plants in flower occupying ground space of 9 feet by 5 feet, H. LOVATT, Esq., Bushbury (gr., Mr. R. Sharpe), was placed 1st with Cannas. 2nd, C. H. MANDER, Esq., Wolverhampton (gr., Mr. C. Weaver), with a nice clean batch of Clerodendron fallax. 3rd, G. H. KENRICK, Esq. (gr., Mr. J. V. Macdonald), with Hydrangeas. An extra prize was awarded to Mr. JOHN E. KNIGHT, Wolverhampton, for decorative Chrysanthemums.

TUBEROUS BEGONIAS covering a table space of 10 feet by 5 feet brought two entries, one exhibit being exceedingly good and the other indifferent. The 1st prize winner was Mr. F. DAVIES, Pershore, whose flowers were unusually large, finely proportioned and variously coloured. In addition to the prize of £7, a Gold Medal was also recommended by the judges.

In the class for a group of plants arranged on a space of 300 feet (open to amateurs only), J. A. KENRICK, Esq., Edgbaston (gr., Mr. A. Cryer), well served the 1st prize of £10. The plants were exceedingly well grown, and many of them abundantly flowered. The same exhibitor gained 1st prize for six stove and greenhouse plants, while H. LOVATT, Esq. (gr., Mr. R. Sharpe), was 1st with six Caladiums and twelve Begonias.

ROSES (OPEN).

Roses were largely and well shown. For seventy-two distinct varieties, Messrs. A. DICKSON & SONS, Newtownards, won the 1st prize. Particularly good were the varieties E. Mawley, Countess of Derby, C. J. Grahame and Dr. Andry.

With three blooms each of twelve distinct varieties, Messrs. A. DICKSON & SONS scored again.

For twenty-four distinct varieties Messrs. A. DICKSON & SONS were placed 1st, and Messrs. J. TOWNSEND & SON, 2nd.

The 1st prize for twelve Roses introduced in the years 1902-3-4 was also won by Messrs. A. DICKSON & SONS; Messrs. B. R. CANT & SONS being 2nd.

For twelve blooms of any dark red Rose (one variety) Mr. HUGH DICKSON and Messrs. A. DICKSON & SONS were placed 1st and 2nd respectively; and for twelve light-coloured Roses (one variety), Messrs. B. R. CANT & SONS, Messrs. J. TOWNSEND & SON, and Mr. HUGH DICKSON were placed in the order named.

With twelve distinct Tea varieties Messrs. B. R. CANT & SONS were 1st, and Mr. HUGH DICKSON, 2nd.

The best collection of six vases of Sweet-Briar Roses, in as many varieties, Messrs. GUNN & SON, Olton, and C. H. MANDER, Esq., won 1st and 2nd prizes respectively.

BOUQUETS AND CUT FLOWERS (OPEN).

THE LEAMINGTON NURSERYMEN & FLORISTS CO., Leamington, secured the 1st prize for a bouquet composed entirely of Orchids, somewhat heavily arranged.

For a bridal bouquet the 1st prize went as mentioned in the previous class; and for a bridesmaid's bouquet Messrs. JENKINSON & SON were the only competitors.

The first award of £10 for an arrangement of hardy border flowers, occupying a space of 15 by 5 feet, was won by Messrs. HARKNESS & SONS, Bedale, whose bold masses of Gaillardias, Lilliums, Spanish Irises, and Campanulas were most effective.

A five-guinea Silver Cup and £20, offered for a display of plants, floral decorations, &c., to be staged in a space not exceeding 200 square feet, went to Mr. JOHN E. KNIGHT, Wolverhampton, with an exceedingly light and tastefully arranged group, in which Carnations, Lilliums, Codiaeums, Cannas, and Bamboos, were the leading features. G. H. KENRICK, Esq., Edgbaston (gr., Mr. J. V. Macdonald), was 2nd with a very creditable display.

Messrs. M. JENKINSON & SON received the 1st prize for a daintily arranged dinner-table decoration, consisting of small-flowered Orchids and Asparagus arranged in rustic stands, &c.

A class for a dinner-table decoration confined to Sweet Peas was keenly contested, Mrs. E. WINCHESTER, Northfield, was adjudged to be 1st.

The £5 prize for the most tasteful arrangement of Pansies and Violas was gained by Messrs. W. FEMBERTON & SON, Bloxwich; with Mr. ALDERMAN WATERS, Acocks Green (gr., Mr. F. C. Brooks), 2nd.

SWEET PEAS.

A class for eighteen varieties of Sweet Peas, occupying a space of 8 feet by 4 feet, brought strong competition. Mr. T. JONES, of Ruabon, had a choice selection, with which he gained the 1st position.

For the special prizes offered by Mr. H. ECKFORD, of Wem, Mr. T. JONES was again 1st.

By far the largest number of exhibitors entered for the SYDENHAM prizes, and, as in the two last-named classes, Mr. T. JONES carried off the principal honour. Mrs. A. G. HOLFORD was 2nd; and Mr. A. HUGHES, 3rd.

FRUIT.

The best four bunches of Grapes, distinct varieties, two black and two white, were shown by Lord SAVILLE, Rufford Abbey (gr., Mr. J. Doe), who had Black Hamburg and Madresfield Court (very good), Buckland Sweetwater (indifferently coloured), and Muscat of Alexandria.

The best two bunches of white Grapes came from W. A. H. BASS, Esq., Burton-on-Trent (gr., Mr. R. Nisbet), 2nd, Lord BAGOT, Rugeley (gr., Mr. T. Bannerman), 3rd, Lord HARRINGTON, Elvaston Castle, Derby (gr., Mr. J. H. Goodacre). The last-named exhibitor had the best green-fleshed Melon, and Lord BAGOT (gr., Mr. T. Bannerman), the best scarlet-fleshed Melon.

The Earl of LATHOM, Ormskirk (gr., Mr. B. Ashton), was 1st with a dish of six Peaches; and Lord BAGOT (gr., Mr. T. Bannerman), 2nd.

The Earl of HARRINGTON was 1st with six Nectarines, and three dishes of Strawberries.

Lord SAVILLE, Rufford Abbey, was 1st with eight dishes of fruit consisting of magnificent examples of Madresfield Court and Buckland Sweetwater Grapes, Stirling Castle and Dymond Peaches, Improved Downton Nectarine, Royal Sovereign Strawberry, Brown Turkey Figs, and Royal Jubilee Melon.

VEGETABLES.

Prizes offered by Messrs. Sutton & Sons, Reading, for six distinct kinds of vegetables, went to Lord ALDENHAM, Elstree (gr., Mr. E. Beckett), the Earl of LATHOM, Ormskirk, and the Earl of CARRINGTON, in the order named.

The Earl of LATHOM was 1st for Messrs. Webb & Son's prizes.

MISCELLANEOUS EXHIBITS.

Messrs. DICKSONS, Chester, sent about a hundred kinds of hardy cut flowers, among which were noted good examples of double and single Delphiniums, Romneya Coulteri, and Gladioli.

Messrs. DOBBIE & Co., Rothesay, contributed fifty varieties of Sweet Peas and a few choice hardy flowers.

Messrs. CLIBRAN & SONS, Altrincham, Manchester, sent hardy flowers.

Messrs. BAKERS, Wolverhampton, occupied practically the whole of one side of a large tent with a superb collection of Sweet Peas, choice Roses, and a rich assortment of hardy herbaceous and alpine flowers, being awarded a Silver Cup in addition to the Gold Medal.

Mr. JOHN FORBES, Hawick, N.B., sent hardy flowers and East Lothian Stocks.

Mr. W. WATERS, Westleigh, Acocks Green, exhibited Violas.

Messrs. WEBB & SONS, Stourbridge, put up a nicely-arranged group of small, well-flowered Gloxinias, Lilies, Sweet Peas, and hardy flowers (Gold Medal).

Messrs. JARMAN & Co., Chard, contributed about sixty varieties of Sweet Peas, and some very good cut Roses.

From Messrs. HEWITT & Co., Solihull, came a large bank of hardy cut flowers.

Mr. C. W. BREADMORE, Winchester, had Sweet Peas. Rustic table decorations beautifully arranged with Carnations and Smilax; also forty varieties of Sweet Peas, including grand vases of Countess Spencer and Orange Countess, came from Mr. ROBERT SYDENHAM, Birmingham.

Messrs. R. SMITH & Co., Worcester, had a group of foliage and flowering plants, and a large collection of cut border flowers and sprays of shrubs.

Choice Melons and vegetables were sent by Messrs. SUTTON & SONS, Reading.

Mr. A. WEBSTER, Head Gardener of the Wolverhampton Corporation, contributed an effective group of plants, consisting of Gloxinias, Liliiums, Cannas, and foliage plants.

Mr. E. MURRELL, Shrewsbury, staged Roses.

Mr. J. H. WHITE, Worcester, sent a representative collection of hardy flowers and cut Roses.

Messrs. T. B. DOBBS & Co. had a display of flowering plants in the open air.

Medals of different value were awarded for most of the exhibits in this section.

CAMBRIDGE HORTICULTURAL.

JULY 11.—The annual flower show of the above Society was held in the very beautiful grounds of St. John's College, Cambridge, on the foregoing date, and in brilliant weather. H. O. Fordham, Esq., is the energetic secretary. The show contained more exhibits than usual, the competition in many of the classes being exceedingly keen. Roses occupied a large area in one tent, and were of exceptionally good quality.

In the class for thirty-six distinct varieties of Roses Messrs. F. CANT & Co., Colchester, were 1st; with Messrs. B. CANT & Co., Colchester, 2nd; and Messrs. J. BURRELL & Co., Cambridge, 3rd. That such well-known growers competed is evidence that the flowers were good and of the finest varieties.

In the class for twenty-four distinct varieties of these flowers Mr. H. DREW, Longworth, was 1st with excellent specimens; Messrs. B. CANT & Co. taking

2nd; and Messrs. D. PRIOR & SONS, also of Colchester, 3rd prizes.

In the class for twelve Teas and Noisettes Messrs. J. BURRELL & Co. were a good 1st; Messrs. B. CANT & Co., 2nd.

Roses were also largely contributed by local growers. In the same tent as the Roses were staged the collections of hardy perennials. A very meritorious display, and one that was admirably set up, was contributed by the Master of Sidney Sussex College. This exhibit embraced twelve distinct kinds.

Another collection containing eighteen hunches came from Dr. J. H. DALTON; JAS. CARTING, Esq., coming 2nd in the same class.

The collections of Sweet Peas formed a striking feature, although many exhibitors require to set up their flowers with greater lightness to produce the best effect. Mr. JOHN HALL had the best twelve bunches of these flowers, and also the best six bunches in the respective classes, the quality, colour and bunching of his flowers being alike excellent.

The best collection of stove and greenhouse flowers belonged to E. B. FOSTER, Esq., who had also the best six bunches of these flowers.

Zonal Pelargoniums were largely shown. M. J. FULLER, Esq., had the best twenty-four bunches, followed by Mr. G. BULL, 2nd; but the latter grower was 1st in the class for twelve bunches, while Mr. H. E. GRAY had the best six bunches.

Plant groups were few in number, but those staged were meritorious. R. L. HUDSON, Esq., set up the best group, which was arranged in a light and graceful manner. The 2nd prize group came from ARTHUR MATTHEW, Esq.

Begonias were a feature, the majority of the plants being well grown and freely flowering. Mr. MATTHEW had the best twelve plants, his specimens carrying superb flowers.

Stove and greenhouse plants were not strongly represented.

Some very good fruit was present. Mr. A. BRISCOE set up the best collection of six dishes. Mr. FOSTER had the best black Grapes in well-finished fruit of Black Hamburg. Mr. BRISCOE took 1st place for Peaches, and also for Cherries. Superb Black and White Currants came from Mr. FOSTER; Mr. DOBBS having equally fine Red Currants.

The various vegetables shown were excellent produce, the basket of eight kinds set up by Mr. DIGGLE being of first-rate quality. This received 1st prize; but Mr. BRISCOE followed closely with good samples.

REIGATE HORTICULTURAL.

JULY 12.—The nineteenth Annual Exhibition was held on the above date in the grounds of Stone House, Reigate, by the kind permission of A. J. Waley, Esq., the President. The Society is in a most flourishing condition, and is fortunate in having secured this enthusiastic gentleman for its President. The beautiful grounds were lighted up in the evening by thousands of fairy lamps producing a very pretty effect upon the steep hill-side.

The exhibition under notice was the most successful ever held in the ancient town of Reigate, there being 1,000 entries. The manner in which the exhibits were staged reflected great credit upon the Committee and hard-working Secretary, Mr. F. Phillips.

The Gardeners' classes were well represented and keen competition was noticeable, and there was a large attendance of visitors.

PLANTS.—In the class for a group of plants arranged for effect there were six competitors, the 1st prize being secured by E. C. P. HULL, Esq. (gr., Mr. H. Burdett), with a lightly disposed group, similar in arrangement to those seen at larger provincial shows.

In the class for four Caladiums, Col. R. W. INGLIS won 1st prize; and for four flowering stove and greenhouse plants, J. WELCH, Esq. (gr., Mr. D. Bone), won 1st prize.

TABLE DECORATIONS.—For six table plants, Col. R. W. INGLIS was again 1st. In the competition for a table of Carnation flowers, J. AUERBACH, Esq. (gr., Mr. W. Blackwood), proved a good exhibitor, staging flowers of good quality. Mrs. FEARON received 1st prize for a table decoration arranged as for six persons.

FRUIT was decidedly good, and a severe competition resulted, the 1st prize for a collection of six dishes being awarded to Col. R. W. INGLIS (gr., F. Phillips). Grapes came from COSMO BONSOR, Esq. (gr., C. Blurton), who secured 1st prize.

Roses were not exhibited so well as usual, the May frosts having done much injury in this neighbourhood. Mr. C. J. SALTER, Woodhatch Lodge Gardens, secured 1st prizes in the classes for eighteen blooms, distinct, and twelve blooms, distinct.

There were several non-competitive exhibits, including one of Water-Lilies from LEOPOLD DE ROTH-SCHILD, Esq., Gumersbury House, Acton. Roses from F. C. PAWLE, Esq. Hardy flowers from Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley; also from Messrs. JNO. LAING & SONS, Forest Hill; and Messrs. SPOONER & SONS, Hounslow.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

AT the recent monthly meeting eight new members were elected. Sick pay distributed to members since the last meeting amounted to £23 2s. William Marshall, Esq., has consented to preside at the annual dinner, which will be held in October next.

NATIONAL ROSE.

EXHIBITION AT GLOUCESTER.

JULY 18.—In beautiful summer weather the provincial show of the National Rose Society was held in conjunction with the annual show of the Gloucestershire Rose Society in the Spa Cricket-field, Gloucester, on the above date. It is ten years since the National Society similarly favoured the city, and no doubt the success achieved on that occasion, combined with the efforts of local Rose-growers, was responsible for a second visit. The total entries for the National and the county sections numbered 304, which constituted practically a record for a provincial show, and resulted in an exceedingly fine exhibition. In welcoming the Mayor of Gloucester, who formally opened the show, Mr. C. E. Shea (President of the National Society) said in reference to holding their provincial meeting in Gloucester, that if ever a decision was justified by results it was certainly the case in regard to that show, which those who had an opportunity of walking round would declare was a magnificent exhibition.

The show on the whole was thoroughly representative, not only in its variety but in the portions of the Kingdom from which the exhibits came. The most coveted among the nurserymen's awards was, of course, the National Rose Society's Jubilee Trophy, which is always competed for most strongly at their provincial shows, and it affords us pleasure to record that our Irish neighbours, Messrs. ALEXANDER DICKSON & SONS, Newtownards, Co. Down, and who have also a large rosary at Ledbury, Gloucestershire, we will not say were well to the front, but were in advance of all competitors for the trophy. In their magnificent winning stand of thirty-six blooms, distinct varieties, were the two finest Roses in the show, Mildred Grant and Helen Keller, which were awarded the National Society's Silver Medal. Among other fine flowers we noticed were Dean Hole, Duchess of Portland, Charles J. Grahame (a beautiful crimson rose awarded the National Society's certificate), Mrs. W. J. Grant, Bessie Brown, Mrs. Sharman Crawford, Florence Pemberton, and Robert Scott—all Roses of their own raising. The 2nd prize was awarded to Messrs. R. HARKNESS & Co., Hitchin, who showed very well, and were in the running with the Irish Roses. The 3rd prize went to Mr. HUGH DICKSON, of Belfast, another Irish grower who has been exhibiting exceedingly well this season. In his stand was a fine specimen of the Rose for which he is responsible, J. B. Clark.

In the next class for seventy-two varieties, open to nurserymen, the Irish Roses again "walked away, hands down."

In the class for twenty-four varieties of three blooms of each Messrs. A. DICKSON & SONS were placed 1st. Here we noticed some delightful trebles of Killarney, the beautiful pink Rose Mamie, and a fine truss of a grand dark Rose; "George Dickson," a large deep crimson, with well-formed, leathery petals—a Rose that might be described in constitution as an advance on Horace Vernet. Messrs. HARKNESS & Co. came in for the 2nd award. The King's Acre Nurseries, Hereford; Messrs. Perkins & Sons, Coventry; G. Prince, Berks; S. Treseder & Son, Cardiff; J. Mattock, Oxford; H. Drew, Berks; and J. Jefferies & Son, Cirencester, also figured in the prize-list.

AMATEURS.

Mr. CONWAY JONES, of Huaclecote, near Gloucester, followed up his successes at recent Rose shows by winning the Jubilee Trophy of the National Society for amateurs—a circumstance which gave a great deal of satisfaction locally. The trophy had been won for a good many years by Mr. LINDSELL, of Hitchin, Mr. Conway Jones having been 2nd to him on three occasions, but Mr. LINDSELL had this year to be content with the 3rd place.

In the city amateur classes the piece of plate given by the Mayor and Corporation for the best display of Roses was won by the Misses PIKE; and the 2nd (a piece of plate) by Mr. JOHN STEPHENS. The Sheriff's prize (a piece of plate) for six varieties was secured by Mr. T. A. WASHBOURN.

The local cottagers' exhibits were a distinct advance on anything previously shown, both in point of number of entries and quality of the blooms. The city member's prizes were won by C. MEEHAM, 1st; W. C. FRITH, 2nd; and A. V. WRIGHT, 3rd; and those offered by Mr. Henry Terrell, K.C., were awarded as

follows: C. MEEHAM, 1st; A. V. WRIGHT, 2nd; and E. BOLTON, 3rd.

It should be added that the Mayor of Gloucester, Councillor W. Langley Smith, entertained a large party of friends and officials to a luncheon on the exhibition ground. In responding to the toast of the "National Rose Society," the President, speaking of the progress the Society had made, pointed out that while ten years ago, when Gloucester was last visited, the membership was only 370, it now stood at nearly 1,600. In congratulating Mr. Conway Jones upon winning the Challenge Trophy he said the exhibition at Gloucester this year was the best provincial show he had ever attended. Referring to the change of *locale* of the metropolitan show of the Society this year from the Temple Gardens to the Royal Botanical Gardens, he said that they took more money at the gate than they ever did at the Temple, while they had also been able to assure the world that the Botanical Gardens were not so far removed from the centre of civilisation as most people thought.

From Another Correspondent.

JULY 18.—This meeting of rosarians was held at The Spa, and resulted in a great gathering of most of the leading growers, trade and amateurs. Amateurs were represented by the Rev. J. H. Pemberton, E. B. Lindsell, Conway Jones, R. Foley Hobbs, W. Boyes, W. Whittle, R. Hill-Gray, Rev. R. Powley, F. Dennison, J. Bateman, and others.

The Roses were staged in a spacious, well-ventilated marquee, and maintained their freshness throughout the day. The quality of the flowers was good. There were many grand specimens. It was noticed that the two most popular flowers in the exhibition were Bessie Crown and White Maman Cochet, which were to be found in almost every stand, grand boxes of twelve being staged. All the classes were filled, and in the majority there was keen competition. The show was well managed, and the executive are to be congratulated on the excellence of the arrangements.

The Jubilee Challenge Trophy (nurserymen), for thirty-six, distinct, was won by A. DICKSON & SONS, Newtownards, with an even and bright collection of well-built flowers, containing very fine examples of Helen Keller, Mildred Grant, Her Majesty, Mrs. W. J. Grant, and Duchess of Bedford, the first-named two winning the Silver Medals for the best H.P. and H.T. respectively; R. HARKNESS, of Hitchin, being a close 2nd with grand specimens of Florence Pemberton, Clio, and Bessie Brown.

For seventy-two, distinct, Messrs. A. DICKSON was again 1st.

The Jubilee Trophy (amateurs), for twenty-four varieties, was won by Mr. CONWAY JONES, of Gloucester, with a stand of bright, fresh flowers, Her Majesty and Horace Vernet being very fine. Mr. F. DENNISON, of Keulworth, was an excellent 2nd with well-built flowers of good substance, and with more lasting qualities than that which at the time of judging obtained the 1st place. To Helen Keller and Mildred Grant, in Mr. DENNISON'S stand, were awarded Silver Medals.

For thirty-six varieties the Rev. J. H. PEMBERTON took the 1st prize.

DECORATIVE ROSES.

In the class for eighteen bunches J. MATTOCK exhibited a magnificent collection, which, staged facing the entrance to the tent, formed an attractive feature. In this exhibit fine bunches were staged of Bardon Job and Prince de Bulgarie. In PAUL & SON'S collection, which came 2nd, were excellent examples of The Queen and Prince de Bulgarie.

For twelve bunches, amateurs, the Rev. J. H. PEMBERTON was awarded the 1st prize for an elegant group, grand bunches being staged of Dorothy Perkins, The Garland, and Crimson Rambler, together with Souvenir de la Legion d'Honneur, Blush Rambler, Madame Alfred Carrière, Laurette Messimy, and Gustave Regis. The 1st prize for six bunches was awarded to Mr. CONWAY JONES.

ROSES IN VASES.

For twelve distinct, five blooms of each, Mr. GEORGE PRINCE, of Oxford, was 1st for a fine lot. Mrs. J. Laing (very fine), White Maman Cochet, Mildred Grant, and Ulster (very good), being the best. The effect of this collection was somewhat handicapped by the height of the vases. Messrs. A. DICKSON and J. JEFFRIES were 2nd and 3rd respectively.

NEW SEEDLING ROSES (GOLD MEDAL CLASS).

The undermentioned Roses were exhibited by A. DICKSON & SONS, but no Gold Medal awarded:—Souvenir de C. J. Grahame, an exceedingly bright-red, pointed, globular hybrid-perpetual, of medium-sized flowers, was awarded a Card of Commendation. The other Rose was Mrs. John Bateman, a cerise hybrid Tea, somewhat short and close in the petal, but very full, globular.

GARDENERS' DEBATING SOCIETIES.

DEVON AND EXETER GARDENERS'.—This Association held their summer outing on the 12th inst., when about sixty members and friends journeyed to the lovely Devonshire sea-side resorts of Lynton and Lynmouth. The party on arrival at Lynton proceeded to Hollerday, Sir George Newnes' marine residence, which is perched on an eminence 800 feet above sea-level, that overlooks the Bristol Channel. From Hollerday the party proceeded to Tee Abbey, which is situated on the coast, at the end of the Valley of Rocks. This place figures in the romantic history of the neighbourhood, and is familiar to readers of "Lorna Doone." Glen Lyn, in Lynmouth, was next visited, the beautiful ravine being found at its best. Admirable arrangements for the party were made by Mr. W. Charley (hon. sec.), and Mr. W. Mackay (hon. treasurer). A. H.

IPSWICH GARDENERS' ASSOCIATION.—A party numbering about fifty members of the Ipswich District Amateur Gardeners' Association spent on Wednesday, 12th inst., by the kind invitation of Mr. Alan Turner and Mr. J. G. Cranfield, an enjoyable time in the beautiful grounds adjoining the residences of these gentlemen at Burstall. The party journeyed by brake and by cycle, and at their destination were met by Mr. Turner, who conducted them over the estate.

SOUTHAMPTON HORTICULTURAL.—The annual garden fête in aid of the funds of the Southampton Horticultural Society was held on Wednesday the 12th inst., and was a great success. The beautiful grounds attached to Sir Samuel Moutagu's residence at South Stoneham were again kindly lent for the purpose. This estate is always beautiful, and on the occasion of the fête was in first-class order, the flower-beds presenting a wealth of bloom.

SCHEDULES RECEIVED.

MOUNTAIN ASH FLOWER SHOW, to be held in the Pavilion, Mountain Ash, on Thursday, August 24, 1905.

NURSERY NOTES.

A HARDY PLANT NURSERY.

The popularity of hardy plants has no stronger evidence than the number of nurseries which have of recent years sprung into existence to cater for this form of gardening. One of the more recent of these is the Fox Hill Hardy Plant Nursery, at Keston, in Kent, belonging to Mr. Reuthe, who has been well known as a specialist in these flowers for many years past. As a commencement Mr. Reuthe has acquired about 4 acres of land situated on the southern slope of a rising ground, and has planted this with many of the finest species of hardy and alpine plants. Many of these are quite new plants; others are older, but worthy of a place in the hardy flower garden. We noted a few of the more striking plants in flower at the time of our visit. (Enotheras were at their best. (E. speciosa, E. missouriensis, with large yellow flowers, a fine plant; E. riparia, growing extensively, made a bold show, it is of slender habit, and produces tufts of yellow-coloured flowers in abundance. Thalictrum Delavayi, that recently received an Award of Merit, was doing well. Aquilegia chrysantha hybrida is a good form of Columbine, the long-sprayed flowers are bright yellow. Coreopsis grandiflora Eldorado represents one of the best selections of this handsome border plant. Ozothamnus rosmarinifolius, a curious Composite, makes a splendid subject for the shrubby or border; it produces dense feathery panicles of white flowers. Many improved varieties of Pentstemon (Chelone) barbata were seen; while a bed of the beautiful Dianthus deltoideus was literally covered with flowers.

Another plant that was a mass of flowers was Cistus salvifolius; C. lusitanicus has an adpressed habit, and develops numerous white flowers pleasingly blushed with rose-colour at the base of each petal, and set off by the deep yellow-coloured stamens. Potentilla Friedrichsenii is one of the shrubby forms of this handsome genus. Linum flavum, as the name indicates, has flowers of yellow colour; it is very effective in the border. The "heads" of Achillea Eupatorium attract attention.

Other good garden plants that we can only name are Bupthalmum salicifolium, Glaucium

Serpieri, Erodium Manescavi, Calandrinia umbellata, Robinia hispida, Iris Monnier, and Agrostemma arosanguinea.

A water-garden is in course of formation, and hardy aquatic and bog plants are already represented by many of the best varieties and species of these plants. Shade-loving plants are accommodated in the cool retreat of an adjoining wood.

Grape-fruit, case	13 0 —		
Grapes, Alicante, per lb. ...	1 0-1 3		

REMARKS.—The Strawberry season is now almost over; good prices are obtainable for selected 1st quality flat punnets, consignments realising 12s. to 15s. per doz. Californian Plums have now made their appearance, making 10s. to 12s. per case of 13 lb. for selected varieties. Cherries have not been so good for several seasons past; some very fine examples realised 8s. to 10s. per peck. Figs are very plentiful, consequently prices for these fruits are low. Supplies of Oranges are over in as much as Spain is concerned; those from Jamaica now arriving are not ripe enough to meet with a ready sale. The supply of Tasmanian Apples from cold storage is now almost exhausted. Trade generally is good.

COVENT GARDEN FLOWER MARKET.

The market all round is now very dull. Many growers have now finished sending for the season. Some good compact plants of Rose Dorothy Perkins are arriving, and these still realise as much as 6s. each. The Crimson Ramblers are almost over. Verbenas the King is very fine. I think there is no doubt that this will supersede the variety Miss Willmott for market purposes. All the Verbenas have to be offered at very low prices to clear. Good Hydrangeas are still seen. Some fine plants of Lantanas in various colours are seen; those in 48's realise about 8s. to 10s. per dozen, and large plants in 32's as much as 24s. per dozen. Campanula isophylla alba and C. Mayi are now very good. Liliun Harrisii in nice dwarf plants are plentiful. There are still many show Pelargoniums seen, but these do not sell readily. Zonals vary very much in quality, some are good, but the majority are inferior. Bouvardias are seen, but are not wanted. Marguerites, both white and yellow varieties, are still of good quality. Among Ferns and Palms there is little variation. Some very good Crotons are seen. Asparagus Sprengeri in fresh-looking plants in 48's and in larger sizes, A. plumosus, and A. tenuissimus are all well grown. Eulalia japonica variegata and Cyperus alternifolius are plentiful. Some growers are still marketing bedding plants. Asters, Antirrhinums, and Zinnias are to be had.

CUT FLOWERS.

There is no improvement in the trade for cut flowers, and many remains unsold. Supplies of best Roses are

perhaps a little short, but there are very large quantities of ordinary quality. Carnations are over plentiful. Sweet Peas cannot be cleared at any price. Liliuns are also very cheap. Lily of the Valley does not sell well. Large quantities of hardy flowers are now coming in the market, of which the double white Stocks are of splendid quality. Gladiolus The Bride is over-plentiful. I noticed some of the choicer hybrid Gladioli are also to be had. Gypsophila paniculata is seen in large heaps. Calliopsis grandiflora is good. There will be no improvement in the cut flower trade until late in the autumn. While so much produce remains unsold it can hardly pay for cutting and sending to market in such large quantities. A. H., Covent Garden, July 19.

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Vegetables: Potatoes, 3s. 6d. to 7s. 6d. per cwt.; new, 1s. to 1s. 3d. per 21 lb.; Turnips, 6d. to 8d. per dozen bunches; Carrots, 6d. to 8d. do.; Cucumbers, 1s. 9d. to 3s. per dozen; Onions, foreign, 2s. to 4s. per bag; Parsley, 4d. to 6d. per dozen bunches; Lettuces, 6d. to 8d. per dozen; Cauliflowers, 1s. 6d. to 2s. 3d. do.; Peas, 4s. to 6s. per hamper; Beans, 3s. 9d. to 4s. do.—Fruit: Oranges, 8s. to 21s. per case; Valencia, 9s. 6d. to 10s. 9d. do.; Apples, Lisbon, 8s. 3d. to 10s. 3d. per box; Bananas, 4s. 6d. to 7s. 6d. per crate; Tomatos, Valencia, 7s. to 9s. 6d. per case.

EDINBURGH.—Oranges, Valencia, 15s. per case; Grapes, English, 1s. 9d. to 2s. per lb.; do. Belgian, 1s. 4d. do.; Lemons, Palermo, 10s. to 18s. 6d. per box; Apples, Australian, 13s. 6d. to 15s. 6d. per case; do. Lisbon, 15s. do.; Bananas, 5s. 6d. to 10s. per bunch; Nuts, Brazilian, 35s. to 38s. 6d. per bag; Nuts, 18s. 6d. to 40s. per cwt.; Figs, 9d. per dozen; Walnuts, Italian, 6s. 3d. per stone; Dates, Hallowil, 15s. 6d. per case; Tomatos, Guernsey, 5½d. to 6d. per lb.; Onions, Egyptian, 4s. per cwt.; do. Valencia, 7s. 6d. to 8s. do.; Carrots, 1s. per doz.

DUBLIN.—Vegetables: Potatoes, new, sandy, 4s. to 4s. 6d. per cwt.; clays, 4s. 6d. to 5s. do.; for clay, choice, up to 5s. 6d. per cwt.; Cabbages, 4s. 6d. to 10s. 6d. per load; Cauliflowers, 1s. to 1s. 6d. per basket; Parsley, 4s. to 5s. per bag; Carrots, 8d. to 9d. per dozen; Turnips, white, 4d. to 6d. per bunch; Salad, 3d. to 8d. per dozen; Scallions (young Onions), 3d. to 5d. per bunch; Thyme, 3d. to 4d. do.; Peas, 2s. 3d. to 2s. 6d. per small bag.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending July 15, 1905.

1905.	TEMPERATURE OF THE AIR.				TEMPERATURE OF THE SOIL at 9 A.M.			RAINFALL.	SUNSHINE.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending July 15, is furnished from the Meteorological Office:—

"The weather at the commencement of the week was close and changeable, thunderstorms occurring on Sunday over nearly the whole of Great Britain, as well as in some neighbouring portions of Ireland. Later on the weather over England improved very materially, but in Ireland, Scotland and Wales it remained somewhat unsettled, with frequent though not heavy falls of rain. Intermittent fogs, often of great density, were reported at many of our coast stations.

"The temperature was above the mean, the excess ranging from only 3° in Scotland, N., and the Channel Islands to 7° in the Midland Counties, and to as many as 8° in England, N.E. and E. At many places in the west and north the highest readings were recorded on Sunday, but over the kingdom generally they occurred on Thursday or Friday, the thermometer on one or other of those occasions rising to 86° and upwards in

most districts, and to 86° in the Midland Counties (at Bawtry). The lowest readings occurred as a rule some time during the earlier half of the week, when the thermometer fell below 50° in many districts, and below 45° in Scotland, N. and E., and Englaod, N.W. At a number of the English stations the thermometer on subsequent nights failed to sink below 60°.

"The rainfall amounted to less than the mean in all districts excepting Scotland, E., and England, N.W., where the normal quantity was just reached. In the latter districts heavy local falls were experienced with the thunderstorms of Sunday.

"The bright sunshine was in excess of the mean in most of the Wheat-producing districts, as well as in England, N.W., and Ireland, N.; elsewhere the average duration was not reached. The percentage of the possible duration ranged from 56 in Englaod, E., and 51 in the Midland Counties, to 29 in Ireland, N., 27 in England, S.W., and 23 in Scotland, N."

THE WEATHER IN WEST HERTS.

A very warm and sunny week.—During the eight days ending on the 15th the weather continued very warm. On all but one day during this warm period the temperature in the thermometer screen rose to or above 76°, and on the two hottest days exceeded 80°. The nights were also equally warm, the exposed thermometer never falling lower than 45°, and on the warmest night 61° was registered, which is, with one exception, the highest minimum reading that I have yet recorded here. Since then the days have been of only about average warmth, but on one night the thermometer exposed on the lawn fell to within 7° of the freezing-point. The ground is now not so warm as it has recently been, but is still 1° warmer at 1 foot deep, and 2° warmer at 2 feet deep, than is seasonable. The fall of rain during the week amounted altogether to little more than a tenth of an inch. Percolation through the bare soil gauge has now nearly ceased, no measurable quantity of rain-water having come through the 2½ feet of soil in that gauge for several days. There was again a splendid record of sunshine, the mean daily duration for the week averaging 8½ hours, or 2½ hours a day more than is usual at this season. As in the previous week, calms and light airs prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon was about three per cent. less than the July average for that hour. E. M., Berkhamsted, July 19, 1905.

For actual temperature and condition of barometer at time of going to Press, see p. 70.]

ANSWERS TO CORRESPONDENTS.

* * * EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plans to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

ACER OBTUSATUM: Sir A. B. H. Fruits of Maples with three carpels are not uncommon, especially in the Sycamore, but we do not remember to have seen as many in this particular species. The presumption is that the ancestral Maple had five carpels, of which three are now habitually abortive.

AGERATUMS: N. S. The bedding varieties of Ageratum are not annual plants, and should not be exhibited in a collection of annuals. An annual is a plant that springs from seed and produces flowers and dies within a given year.

"ALPINE FLORA." Tourist. You will find Dr. Hoffmann's book on this subject, called Alpine Flora, translated by Mrs. A. Gepp, suitable for your purpose. It contains numerous coloured plates and is published by Longmans, Green & Co. A similar work, but in German, is noticed at p. 70. M. Correvon's Flore Colorée de Poche (Paris: Paul Kleinsieck) may also be commended to your notice. If you want a more complete book, apply to David Nutt, Long Acre, for Paitson's Translation of Gremli's Flora of Switzerland; but this has no illustrations.

ASPENIUM: A. H. P. You should send specimens that we may see them.

BEAN RUST: W. W. The rust is the work of a fungus, Uromyces fabæ. Spraying with dilute Bordeaux-mixture arrests the spread of the disease. In dealing with small breadths of Beans in gardens spraying with potassium permanganate or potassium sulphide is as effective

and is more readily obtainable. Infected plants should be burned as soon as the Beans are gathered, and not on any account be thrown on the manure-heap or the disease will be perpetuated. Wild Vetches are liable to become infected with the same disease, and should not be allowed to grow in hedges or waste places near the garden.

CARNATION: *G. R.* Your pure white Carnation Queen Alexandra is very good in many respects, but we doubt if it would find favour with the Carnation specialists, who would reject it at once as a show variety because of its fimbriated petals. The non-splitting calyx is a good feature. You should have submitted it to the National Carnation Society on Tuesday last.

CORRECTION.—On p. 43, col. 3, for *Klotzschiana*, read *Koschnyana*.

CUCUMBER: *G. B. M. R.* The powdery mass consists of the spores of a slime fungus called flowers-of-tan—*Ethalium septicum*. Except by smothering the plants it is not injurious, and if in abundance it can be got rid of by syringing.

CURRENTS: *C. P.* A fasciated bunch due to the union of several branches. Common in many plants, but we never saw it in Red Currants before.

EMPLOYMENT AT KEW: *Constant Reader.* Candidates for employment in the Royal Gardens, Kew, should be over twenty but not more than twenty-five years of age. They must have had at least five years' experience in good private gardens or nurseries. Apply to the Curator, who will send you a form of application.

EXPORTING ORCHIDS: *E. C., Java.* *Vanda suavis*, *Coleogyne speciosa*, *Bulbophyllum Lobbia*, and most of the other species you mention are plentiful enough in gardens here, and certainly would not pay you to send as established plants in Wardian cases. *Phalenopsis* and other plants likely to be profitable to the sender have to be specially prepared and forwarded by the quickest route, with an attendant to look after each consignment on the journey. It is expensive, but this is the only system that will ensure a return for the outlay. To send Orchids from Java with any degree of certainty that they will arrive in good condition it is necessary that they should be forwarded in the resting season. Ordinary packing-cases would not be satisfactory throughout, although occasionally plants might get through in that way. The question of freight and the determination who should take the risk is subject to arrangement between sender and consignee, but importers are very much averse from taking risks in such cases. It would never pay to buy Wardian cases in Europe to be sent out empty for the purpose of exporting Orchids to this country. If you elect to make the venture you could get them much cheaper in Java. We advise great caution in undertaking such a business. We know of no work dealing commercially with Java Orchids.

GRAPES SWEATED: *A. B. C.* We suppose you mean what is termed scalding, an injury which is caused by a lack of ventilation early in the morning when there is bright sunshine. All you can do is to cut away the berries which are affected most, and prevent a similar occurrence in the manner indicated above.

GROUND AROUND BUNGALOW: *Ajax.* Consult a solicitor.

HARDY PERENNIALS: *J. R. H.* The compilers of the schedule may have intended to include only herbaceous hardy perennials, but as it was not stated, the Roses and Clematis were permissible, both species being hardy perennials.

INSECT ON POTATO: *C. S. & Co.* All we find is a ladybird, which preys on the green-fly.

MARÉCHAL NIEL ROSE: *Sir C. S.* The injury generally results from frost or some other cause that ruptures the bark and sets up irritation in the cellular tissue. We have never been able to discover that a fungus or insect had anything to do with it.

MELON: *F. E. C.* The small ornamental Melon you send is the sweet-scented or Queen Anne's Pocket Melon. The perfume, which resembles

that of other Melons without being so strong, is rather agreeable as the fruit ripens, but the taste is not equally pleasant, and the plant is consequently only grown as a curiosity or as an ornamental climber.

MELON CANKER: *Anxious.* The plant is badly affected with canker. Try an application of lime and wood-ashes on the wound, or turn out the plant if the case demands it.

NAMES OF PLANTS: *W. T.* *Cornus suecica*.—*A. K.* A variety of Ivy (*Hedera Helix*), probably pedata.—*Nil Desperandum.* *Erigeron speciosus*.—*E. C. C. D.* *Rubus phœnicolasius*; *Hieracium aurantiacum*.—*D. W.* 1, *Olearia Haastii*; 2, *Hippophae rhamnoides* (sea Buckthorn); 3, *Ligustrum lucidum*; 4, *Spiræa arifolia*; 5, *Lonicera Ledebourii*; 6, *Rhus Cotinus*.—*H. E. W.* 1, *Asplenium Ruta-muraria*; 2, *A. trichomanes*; 3, *Ceterach officinarum*.—*J. A. B. R.* 1, *Dianthus plumarius* var.; 2, *Veronica (garden hybrid)*; 3, *Calochortus venustus*; 4, *Mimulus cardinalis*; 5, (*Eurotia eximia (marginata)*); 6, *Erigeron mucronatum*.—*W. R., Liverpool.* The plant is *Orobanche minor*, a parasitical plant perhaps introduced with seed.—*J. M.* *Saponaria Vaccaria*, *Asplenium trichomanes*.—*C. E.* *Selaginella Poulteri* var. *auræa*.—*F. C. E.* *Selaginella*.—*W. T., Derbyshire.* The Orchid is *Odontoglossum crispum*. The Begonia may have been kept in too close an atmosphere, and subjected to excess of moisture at the top.

NECTARINES: *Nectarine.* These fruits are very liable to split from the cause you describe. Place the pots on some moisture-holding material, so that the soil in the pots will become dry more gradually. Do not apply any more manure of any kind. The skin of certain varieties of Nectarine is very apt to shrivel if the sun's rays reach them at a time when the skin is in a damp condition.—*E. H. C.* Irregular growth, probably due to alternations of moisture and drought.

NURSERY: *Rufus.* The rent varies according to the value of the land, labour, building, and materials in a particular district. If the rent is sufficient to pay about 7 per cent. on the capital value it is reasonable.

ODONTOGLOSSUM CRISPUM: *Selsdon.* As soon as your plants of *Odontoglossum crispum* pass out of bloom, a period of rest should follow. This will be induced by keeping the rooting medium moderately dry, the house cool, well shaded and ventilated, and the atmosphere moist by frequently damping the stages, floors, &c. The dry conditions at the roots should not be permitted long enough to cause severe shrivelling in the pseudo-bulbs. A good practice is to spray the plants overhead in the morning, and again late in the afternoon, for by this means frequent watering of the potting materials is obviated. When the new growths develop and have attained to a length of a couple of inches, the necessary potting operations may be given attention. Plants having ample pot-room, and being in satisfactory health and condition, will only need a renewal of the surface materials. Those selected for shifting into other pots should be turned out of the old ones, have all the leafless pseudo-bulbs removed, and a large portion of the old potting material. Then pot them up into receptacles that will be large enough for two years' growth, filling the pot half full of drainage material, and the remainder with good peat and sphagnum-moss, used in equal proportions. Make this compost moderately firm, but not hard, and let it be level with the rim of the pot, and well up to the base of the new growths. If a small portion of decaying Oak-leaves be introduced, try to keep it below the surface, or use chopped sphagnum-moss alone to finish off the potting operation. After this work has been done continue to treat the plants as described above until root-growth becomes active, when more liberal supplies of water should be given. If the house is in a dry and exposed position, employ the top ventilators only, leaving these open at night when the weather is favourable.

ODONTOGLOSSUM CRISPUM: *Old Subscriber.* A white unspotted flower with less yellow on the lip than usual.

PEAR LEAVES: *J. R. P.* We have never known the Pear midge to injure the leaves of the tree. Indeed, it would be impossible for them to do so seeing that they (the larvæ) spend the whole of their lives inside the embryo fruit.

PEAS: *C. C.* The Pea-stems are badly attacked by the fungus named last week. There is no evidence that the maggots have injured the roots. If the manure is sprinkled with kainit when it is turned the maggots will be destroyed.

PROPAGATION OF PLANTS: *W. R. S.* Most plants are propagated both by buds or by tubers, which are modified buds, and by seed. If the development of tubers is in excess, the flowers are likely to be deficient, and *vice versa*. There is no special name to express what you have described.

PURPLE PODED PEA: *W. D. A.* Of little value for culinary purposes.

ROSE-BRANCHES INJURED: *A. J. Fender.* The twig you sent contained a chain of eggs of the Rose sawfly, *Hylotoma rosæ*, Lin. This the female sawfly accomplishes by piercing a hole with her ovipositor in the twig of the food-plant, and as a result the growth of the tissues of the twig is arrested, causing it to curve downwards and inwards on the infected side. As a remedy we would advise you to cut off the diseased shoots and burn them.

ROSES: *Essex.* *Pharisaer*, *Prince de Bulgarie* and *Pauline Bersez* are all excellent varieties for growing in the open, being vigorous, free-flowering and suitable for use as cut flowers. *Hélène Welter* is a new variety not in general cultivation. The variety *Lamarque* is a very free-flowering Rose, but sensitive to cold, and would require a favoured situation outside. *J. B. Clarke* is a new variety, evidently an acquisition for exhibition purposes, but its behaviour in the flower-garden has to be determined.—*W. H. C.* We cannot undertake to name varieties of Roses, or other florists' flowers. Send to a trade grower who has means of comparing them with flowers in his collection.—*Amateur.* We cannot recommend French nurserymen. Advertise in the horticultural Press. In regard to the question of budding, the present is a suitable time for the operation; but do not delay, as the proper season for this work will soon be past. Do not cut the Briars back before budding, but leave them until next March.

SOLANUMS: *Constant Reader.* There appears to be no disease in the plants you have sent us, but the flowers have failed to set from some reason which we cannot determine here. Do not apply stimulating manures to the plants when they are flowering, nor keep them in too high a temperature.

STRAWBERRY PLANTS: *North East.* When the crop has been gathered, if you determine to keep the plants for another year, let all the old foliage be cut away, and then spray the plants with water in which flowers of sulphur has been mixed. Do not obtain layers from these plants.

SWEET PEAS: *T. C.* The leaves have been eaten by the larvæ of some insect, but what we cannot tell.

VINE: *A Reader.* The black dots are the excreta of some insect, readily removable with the point of a knife, and will do no harm; but perhaps the insect may do harm, and a sharp look-out should be kept for it.

COMMUNICATIONS RECEIVED.—*S. W. F.*—*W. P. & Sons—Sulton & Sons—Dr. Schönland. Grahamstown—C. B. C.*—*J. H. P.*—*R. S., Luscombe—T. H.*—*W. H. Y.*—*L. M.*—*L. S.*—*Rev. J. H. P.*—*J. H. W.*—*A. D.* (slips will be sent to you).—*G. H. S.*—*H. R. G.*—*E. L.*—*J. S.*—*T. B. B.*

DIED.—*Mrs. H. Richardson.* On July 7, Mrs. H. Richardson, wife of Mr. H. Richardson, horticultural sundriesman, of Camden Town, London. Mr. Richardson desires to thank many friends who have expressed sympathy.

OUR FRUIT REPORT.

ONCE again we have to thank the numerous correspondents who have favoured us with information concerning the fruit crops for the present year. As in 1903 we have a deplorable record to chronicle, though not quite so unfavourable a one as in that year. The full details are given on succeeding pages, together with a summary on p. 87, which will show the state of affairs at a glance. By way of illustration let us take the figures relating to the Apple-crop in England as the one of most importance commercially. The total number of records from north and south and east and west for England alone is 192. Of these, an average crop is recorded in 28 cases only, while 163 are reported as under and only one as over average. This solitary instance is so remarkable that it may be of interest to record the precise locality—viz., Cranford, Middlesex. In the case of Apples we may also note that some of our correspondents have made no return other than a dash (—). We have taken that to mean a failure of the crop, as it is not probable that any of our reporters have no Apple trees under their care.

With Pears the record is a trifle, but only a trifle, more satisfactory, there being 48 averages against 141 under average. Here again there is a solitary instance of the crop being over average. This time the favoured locality is in Derbyshire.

Plums are the most important crop next to Apples from our present point of view, but of 191 replies from England alone, 50 record an average crop, 10 are over, and no fewer than 131 under average. Cherries are reported on by 180 observers. The average here is good—viz., 104, 10 being over, and 66 under average. It is not obvious why Cherries should have been so favoured.

Peaches, Apricots, and Nuts we may pass over without special comment, but "small fruits" show a more favourable record than Apples or Plums, thus of 192 replies received from England, 97 show an average crop, 73 are over average, and only 22 under. For Strawberries we received 191 reports from England, 92 being favourable, 44 over average, and 55 under average.

The returns from Scotland, Wales, Ireland, and the Channel Islands tell their own tale, and need not be specially referred to here.

As to the causes which have induced this poor show of fruit, we do not think we have any need to inquire further. Spring frosts and east winds occurring at or about the flowering period are responsible for most of the mischief. As these occur pretty regularly, it would seem as if our hybridisers and cross-breeders had been lacking in enterprise, or they would have long ago given us later-flowering or more hardy varieties.

A TRIAL GROUND.

BANDS of colour, belts of colour, strips of colour—colour everywhere—blue, crimson, red, yellow, white, in beds, in borders, in lines, in circles, in serpentine waves. And the colour was, with one exception, pure of its kind, without shade or blend. This is what Messrs. Sutton's trial-grounds at Reading showed from the windows of the train one hot July day. A closer inspection on the ground showed, not self-colours, but an infinite variation, gradation and blending of tints. So much for looking at things at a distance and at close quarters. The exception we have alluded to was a marvellous mosaic, or rather several beds, of shades of yellow, crimson, and purple, with scarcely a green leaf to be seen. These mosaics appeared as such both on a distant and on a near view; and the constituents were not of glass nor of coloured stone, but of flowers—flowers of various kinds of dwarf *Tropaeolums*, grown in admixture, suggesting a huge flower-salad or a creamy mayonnaise speckled with red and purple. Those who love bright colours and striking effects should take note of these beds of mixed *Tropaeolums*.

But as to the details—where are we to begin? Still more important, where are we to leave off? How are we to arrange our materials? Perhaps, if we "cool our eyes" a little on the grass plots first, we may find a way out of the maze of detail. These grass plots are very interesting. Each plot is devoted to one species; one forms a dense, smooth carpet; one is patchy, one burns in a dry season, whilst its neighbour keeps its green colour. We will not burden the reader with the names of these grasses; we allude to the matter to show how Messrs. Sutton acquire their experience, which enables them to "prescribe" for the formation of croquet-lawns, putting-greens, cricket-grounds, and other requirements on varied soils and under different conditions. These plots are, of course, kept mown and rolled; but hard by are similar plots in which each species is allowed to do its best, and prove its right to the name it bears. To the student of grasses it need hardly be said that these plots are most instructive, but so brilliant are the masses of many-hued flowers that when the eyes have rested a little the fascinations of colour exert their sway, and we find ourselves saying, "What's that? and that? and that?" and even admiring a ribbon border of the old pattern so much in favour a quarter of a century ago. This one must be 1 or 2 furlongs in length, and it is formed of a row of dwarf pink *Godetia* in front, one of *Duchess of Albany* (white) in the middle, and at the back *Scarlet Queen*, a

little taller than the others. That the lines are so true, so free from rogues, so uniform in stature and flower, is a striking testimony to the careful selection and excellence of cultivation bestowed on the plants. Of course, the "ribbon" is made in conformity with the particular requirements of the case. We should not recommend its general adoption in gardens. Elsewhere these *Godetias* are grown in single beds, one variety to each bed. One known as *Crimson King* was particularly effective. *Bridesmaid* is another beautiful variety with white and pink-flushed flowers. But if we once begin to enumerate varieties, the prospect of bringing this article to a close will be remote.

It must suffice to say that at this particular time the *Godetias* contributed the most important feature of the display so far as colour is concerned. Next in order in this respect were the *Tropaeolums*, to which we have already referred. They vary greatly in habit; some are loose and rampant, others compact and tufted, of which *King of Tom Thumbs* is specially noticeable; some with leaves of a greenish-purple hue, such as *Empress of India*; others, like *Cloth of Gold*, so yellow that even when not in flower they are serviceable as bedders; and as to the flowers they are of all shades, cream colour and yellow, passing to deep red, and some, like "*Chameleon*," not knowing which colour to adopt, make a compromise by forming stripes of red on a yellow ground. Truly a wonderful range of variation in one species, and as they, like the *Verbenas* and many other plants mostly come true from seed, it is clear the old notions of species must give place to conceptions more in accordance with facts. *Clarkias* are near allies to *Godetias*, but generally with smaller flowers, some with flakes and marginal spots as in a *Picotee*.

As to *Stocks* and *Antirrhinums*, *Lobelias* and *Candytufts*, *Seedling Carnations* and *Sweet Peas*, we can only mention them as contributing in no small degree to the beauty of the trial-grounds. But there are so many plants of which a like remark might be made that we are compelled to pass them by and confine our attention to a few specialties like the *Eschscholzia*. In addition to the ordinary single and double yellow varieties, there are masses of "*Mandarin*," in which the outer surface of the petals is of a deep orange colour, and the very beautiful *Rose Queen*, in which the petals are white, deeply flushed with rose on the outer side. *Miss Jekyll* is commemorated by a tall-growing *Nigella* with azure-blue petals. The so-called *Swan River Daisy*, *Brachycome iberidifolia*, has slender, wiry, glabrous stems, very finely cut leaves and long-stalked flower-heads, each about the size of a sixpence, the ray florets of a blueish-violet surrounding a blackish "disc." Seen in the mass this is both novel and beautiful. *Chrysanthemum* "*Morning Star*" is very conspicuous. It is said to have been selected from the wild, corn-field weed, *C. segetum*, and has robust stems, succulent foliage and bold flower-heads of a creamy-white or pale sulphur-yellow colour. A "*British Botanist*" coming across such a specimen would have "his mind improved" as to the extent and limitations of the process of variation.

Coreopsis grandiflora is well known, but worth notice for the size and attractiveness of the yellow flower-heads, which do well for purposes of table decoration. Moreover, if autumn-sown it is said to withstand our winters with impunity.

Nemesia strumosa was an introduction of Messrs. Sutton, who have "improved" it in variety of colour: but further improvement is needed as to habit. *Lavatera* "*rosea splendens*" is a selected variety of *L. trimestris*, with larger, more perfect, and deeper-coloured flowers than the type. *Diascia Barberae* is a plant that will interest the botanist, as the corolla has two spurs, and thus approximates to the peloriate variety of *Linaria*.

Our note-book is not half exhausted, but the patience of the reader will surely give out if we go on longer. We have said enough to show the almost infinite diversity of colour and form, to say nothing of interest, which is spread out before the visitor in the Reading trial-grounds at this season.

REPORT ON THE CONDITION OF THE OUT-DOOR FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS.]

THE WORDS "AVERAGE," "OVER," OR "UNDER," AS THE CASE MAY BE, INDICATE THE AMOUNT OF THE CROP; AND "GOOD," "VERY GOOD," OR "BAD," DENOTE THE QUALITY.

. FULLER COMMENTS WILL BE GIVEN IN THE FOLLOWING NUMBERS. SEE ALSO LEADING ARTICLES ON PAGES 81, 90.

The Week's Work.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq.,
Copped Hall, Epping, Essex.

"Rex" Begonias.—In order that the plants may fully develop size and brightness of foliage, they should be planted out on a wall prepared for the purpose where there is shade and moisture with ample light. Young plants can be easily raised at the present time from perfectly developed leaves, which should be laid on the surface of silver sand or cocconut-fibre in boxes, and made secure by means of wire pegs. The boxes should be stood in a shady position in a house having a warm, moist atmosphere, and be syringed occasionally.

Philodendron Lindeni is another useful plant that is seen to the best advantage when growing from a wall together with *"Rex" Begonias*, of secured to the pillars in a stove-house. The best method of propagation is to divide an old plant, that has become leggy, into pieces consisting of two or three joints in each, and inserting them singly in small pots, and plunging them in a bottom-heat, where they will make roots quickly. Plants propagated at the present time will be useful for planting out next spring.

Passiflora quadrangularis.—This is one of the most useful stove climbing flowering plants that should be selected if it is desirable to cover a large area quickly. The plant gives little trouble beyond that of regulating the growths occasionally, and of maintaining an abundance of moisture at the roots and overhead. Well-matured growths, if cut in pieces of about a foot in length and inserted in cocconut fibre, will make roots readily, and should afterwards be taken out and potted-up. When again established they may be planted-out.

Eucharis grandiflora.—Those plants that flowered some time ago will by now have completed their growth, and should be afforded rest by removing them to slightly cooler quarters. Less water at the roots will be required, but on no account must they be allowed to become dry. Let the foliage be sponged carefully with soft-soap and water, and by this means remove all traces of mealy-bug and thrips.

Smilax (Asparagus medeoloides), &c.—This useful decorative plant requires little attention beyond that of supplying water to the roots and of supporting the growths with some string strung vertically. Continue to propagate *Tradescantias*, *Oplismenus Burmanni variegatus (Panicums)*, and other "edging" plants, to replace those that have become ragged and untidy.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK
WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Cypripedium Lawrenceianum.—The essential needs of this easily-cultivated decorative species are as follows: Considerable heat and moisture, and rather dense shading, conditions that can generally be supplied in any East Indian-house. Having recently flowered, the plants, which are most effective when grown as specimens, should, where needed, be pulled to pieces and remade. Use moderately large and shallow pans half filled with drainage material, and as a rooting medium equal parts of turfy peat and sphagnum-moss. Separate the old back growths from the one which flowered last, and select pieces from the latter of average size and merit to make the new specimens. The potting material should be applied rather loosely, but sufficiently firm to secure the growths in position. When completed, place the plants on a bench in the conditions described above, and afford them water overhead almost daily. The old portions of the plants should be placed on a moist stage until many of them push forth new growths, when these in turn may be converted into other specimens. *C. Gowerii*, a hybrid from the above species and *C. Curtisii*, is also a very desirable kind, and will thrive under similar conditions and treatment, though, being at present rare, pots rather than pans will be suitable.

Cypripedium barbatum.—Since hybridisation has given us so many more attractive flowers this species has been somewhat relegated to the

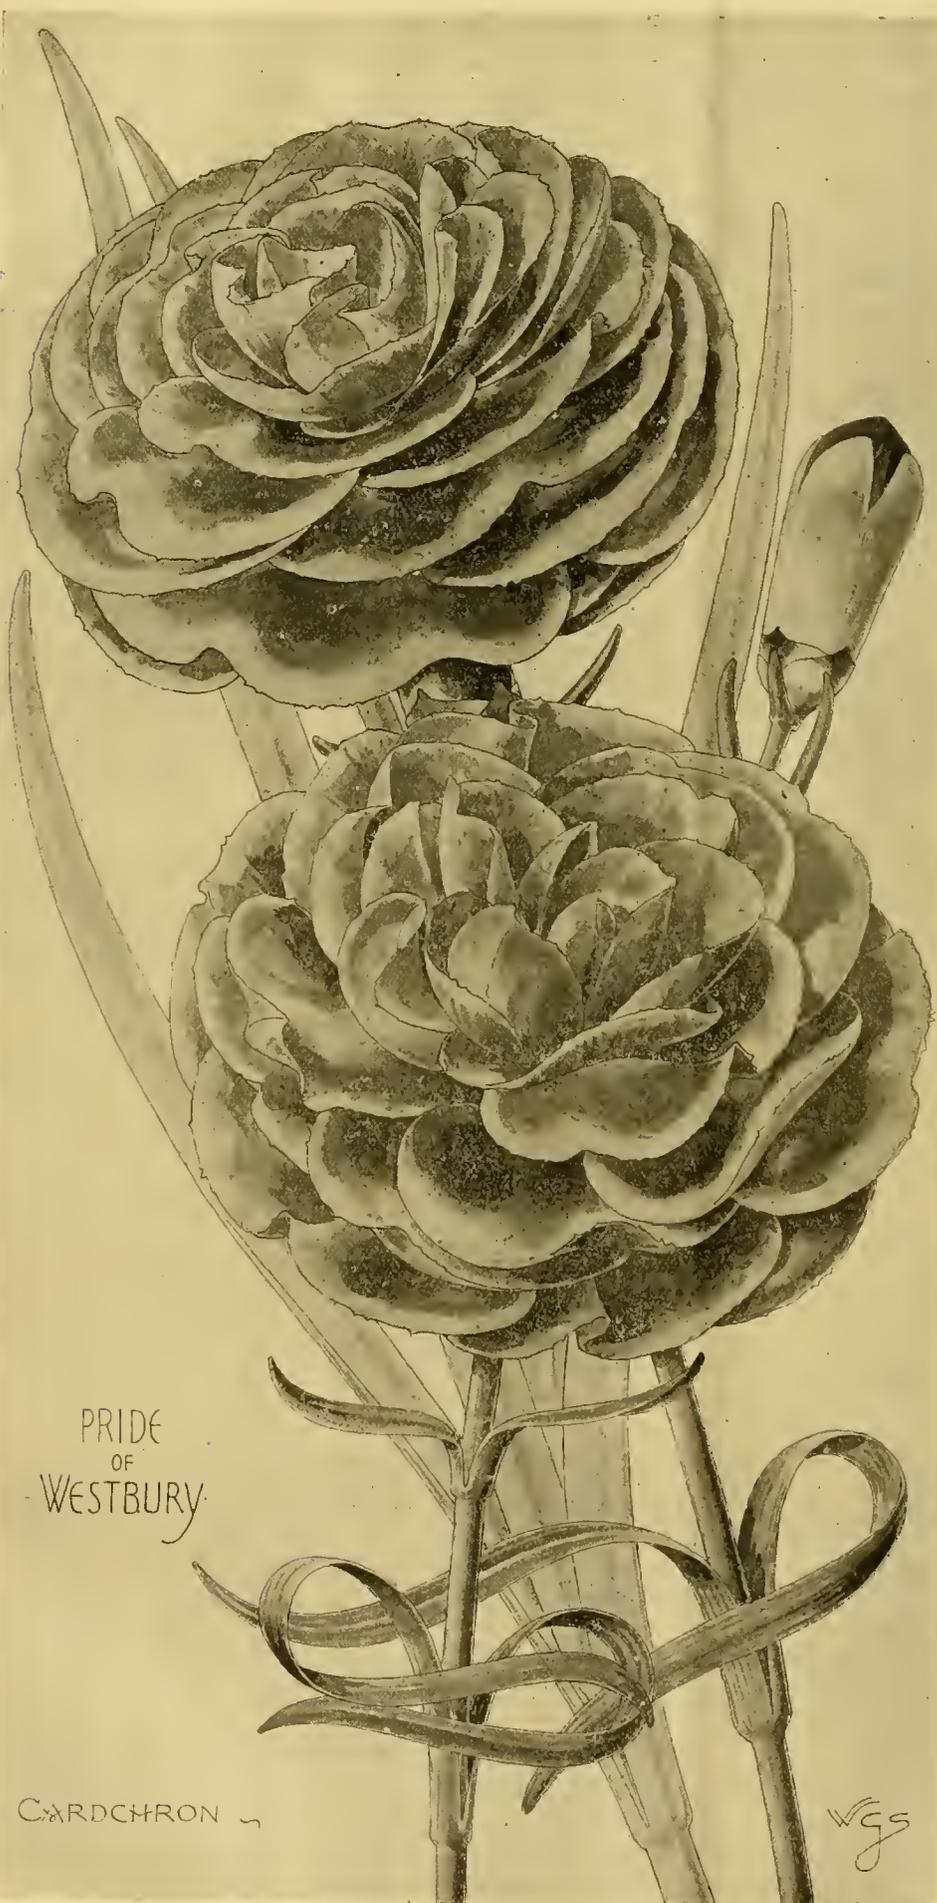

FIG. 30.—BORDER CARNATION, PRIDE OF WESTBURY: COLOUR OF FLOWERS CHERRY-RED,

For which Sir Samuel Scott obtained an Award of Merit at the
Royal Horticultural Society's Meeting on July 4.

background. It is, however, a useful kind for supplying flowers for cutting, as some varieties, such as *C. b. nigrum*, *C. b. giganteum*, and the pretty *C. b. Warneri*, have decided merit. Culturally they may be treated in the same manner as the above, and should there be a spot where they cannot be staged, plants of this species may be placed there. In the Phalænopsis-house here, a portion of the stage, being too near the suspended plants to allow of its being used in the ordinary way, is covered with *C. barbatum*, which thrives so well that two crops of bloom are yielded annually. A thin layer of crocks is placed on the stage, and the plants are held in position with a thin, loose layer of peat and sphagnum-moss. Water overhead is afforded abundantly whenever the least sign of dryness appears.

Cypripedium callosum would not call for any special notice were it not for the remarkable variety known as *C. c. Sanderæ*, which should be in every collection. Plants of the typical forms should be grown in good-sized, well-drained pots or pans in a situation as advised for *C. Lawrenceanum*. They should not be disturbed at the roots except when it is absolutely necessary, but it is essential that the plants should have fresh, sweet surface materials. To increase the number of growths divide the rhizomes of the back growths with a thin-bladed knife, being careful not to detach any of the living roots. *C. x Maudia*, a hybrid between *C. c. Sanderæ* and *C. Lawrenceanum* Hyeanum is a superior form, which deserves to become very popular.

Sophranitis grandiflora.—This attractive Orchid is now pushing forth new growths, which in due course should each produce brilliantly-coloured flowers. The plants should at this season occupy a position far removed from the roof-glass, on a stage in the coolest and most shaded house. They may be grown in well-drained pots or pans in ordinary Orchid compost, or in one having a little decaying Oak leaves introduced. When the latter is used more of compost is necessary, and the surface should consist of sphagnum-moss alone. Repotting or renovation of the surface may be carried through in the near future, afterwards keeping the materials moist by spraying or careful watering. Vigorous root action does not take place until later in the season, but when it occurs a good supply of water is needed. Hybrids between this and other Orchids need treatment in accordance with the known peculiarities of the other species concerned. If the hybrids are from *Cattleya anrea*, moderate heat is needed, but if from *C. Harrisonia*, cooler treatment is desirable.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Watering.—This is an important operation in fruit cultivation, and the weather this season being very dry, particular attention should be given to trees growing on walls. The raised border keeps the roots of the trees drier than the other parts of the garden, and the bricks and mortar below the surface absorb a large amount of moisture. In many gardens such borders will have been mulched some time ago, and this is a great help in hindering the sun's rays from extracting the moisture from the soil. For the production of fine fruit, moisture is essential. Trees which are swelling crops should be given periodical waterings—one or two applications weekly will not be too much on light, porous soils; but soils of a more retentive character will not require water so frequently. Liquid-manure may be given at each alternate watering, either poured on to the ground and watered-in immediately afterwards with clear water, or diluted before application. Where this cannot be procured in sufficient quantity, one or other of the well-known commercial manures may be used according to the instructions issued with each; be careful to apply less rather than more than is recommended. Trees ripening their fruits should not be so watered, otherwise they will split.

Trees planted last season will require sufficient water to keep them growing and healthy, and in many instances the formation of fruit-buds on such trees requires an extra amount of nourishment.

Apricot and Peach-trees should be examined daily, as the earlier varieties are now ripening. For home consumption only the ripe fruits should be gathered, but those required for packing should be gathered before they are quite ripe, as they will ripen during the journey, and there is less risk of bruising them. Care should be given in taking these fruits from the tree, as some varieties adhere to the branch much more closely than do others. What pressure is needed should be applied at the base of the fruit next the branch, the fingers so holding the fruit that no bruise will result.

Strawberry-beds.—Where the fruit has been gathered the beds may now be cleared of all runners, removing with a sharp knife the oldest leaves from the plants; but do not denude them severely of foliage, or it will check the building-up and formation of fruiting crowns for another season. Clear the beds of all weeds and the straw mulching, stirring the surface-soil afterwards with a Dutch hoe.

Birds.—In consequence of the dry weather and the absence of other food for birds, all small fruits must be protected from them by netting.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Pines.—Now that most of the fruits have been cut from the early Queens, thoroughly cleanse the pit and make it ready to receive the smooth Cayennes and other winter-fruiting plants, which generally show the fruit at about the present time. It is not always advisable to put in much fresh fermenting material at this season of the year. The quantity required to keep up a steady bottom-heat of 85° to 90° will depend on the amount of fresh material that was put in last winter. All the material, however, should be cleared out of pits at least once each year in order to get rid of crickets, cockroaches, &c., and the walls should be well washed with hot lime-wash. Plunge the plants at distances of 2 feet apart, and give careful attention to ventilation, watering, and to keeping the atmosphere moist, using as little fire-heat as possible in all the divisions.

Succession Plants.—The re-arrangement of the first division will cause the second division to need filling up, and unless a sufficient number of plants are in their fruiting pots, others that require potting should be attended to at once. Do not disturb the beds very much to induce a flush of bottom-heat. Keep the plants growing steadily until it is time to rest them, by ventilating the pit freely during the early part of the day, but closing it again early in the afternoon, with plenty of moisture.

Suckers.—The general stock of suckers from the early Queens should now be potted up, although it is best to pot up a few of the strongest at intervals as they become large enough. Use pots 6 to 8 inches in diameter, according to the size of the suckers, plunging them in an old pit with sufficient fermenting material to keep the bottom-heat at about 90°, care being taken first to thoroughly cleanse the pit. Afford water sparingly until root action has commenced, and spray the plants overhead each afternoon at closing time, keeping the atmosphere of the pit rather close and moist for a few weeks. Shade the plants lightly during the brightest part of the day, gradually increasing the ventilation and withdrawing the shading as the plants become rooted.

Cucumbers.—Young plants may now be planted or seeds may be sown to succeed those that have been fruiting during the summer months. These plants will then supply fruits during the autumn. Those intended for winter-fruiting may be grown sturdily, and have all the early fruits removed from them. Where plants which have fruited are allowed to remain, remove any old growths if the plants show signs of weakness from over-cropping, and afford them a light rich top-dressing, and stimulants to encourage fresh growth. Sow seeds at about the middle of next month for winter-fruiting, and encourage them to make strong, sturdy growth by free ventilation, planting them in a compost containing rather more loam than is generally used for Cucumbers.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Celery.—The maggot of the Celery-fly has been very active in some quarters this season. The only remedy which I have found to answer is to crush the grub between the finger and thumb, removing and burning the affected parts of the foliage. If an insecticide were used sufficiently strong to kill the maggot the plant would most assuredly suffer, as the maggots have hatched from eggs deposited between the upper and under surfaces of the leaf. Plants intended for September supply will now be well advanced, and should have all suckers removed. Keep the outer leaves tied well together by the use of raffia, making sure that this is not tied sufficiently tight to break or injure the centre leaves, which are the edible portion of the plant. Afford the plants liberal supplies of water, with occasional doses of diluted liquid manure. The Celery is a gross-feeding, free-rooting plant. It will be found by this time that at the surface of the trenches there is a mass of fibrous roots which will be considerably benefited by a top-dressing of some light, rich material. This top-dressing will assist in keeping the plants from "bolting." Celery intended for exhibition in August will require close attention in order to get it perfectly clean and well blanched. I have found the benefit upon many occasions of removing all the blanching material, thoroughly washing the plants with clear water, removing insects or decaying substances, and then applying fresh and clean material.

Carrots sown for pulling in the autumn may be thinned to 3 inches apart. When rain is apparent apply a good dusting of soot. Take every opportunity to destroy weeds in this and every quarter of the garden.

Onions that were raised in autumn and were transplanted in the spring should have their necks twisted, with the object of obtaining better maturation in the bulbs by preventing an over-development of top-growth. Pull any that are already matured and expose them to the sun, where they will become of good condition for storing.

Parsley.—The present is a good time to sow seeds for raising plants to supply Parsley during winter. Sow the seeds in drills 1 foot apart in different aspects, so arranged that frames may be placed over the plants. Splendid Curled is an excellent variety.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Roses.—Budding is the principal mode of propagation. If stocks of Briar standards, cuttings, or seedlings were planted out last winter, they will soon be ready to be operated on. Choose plump, half-ripened buds. If standards are used, bud on the medium-sized laterals as near to the main stem as possible. The shoots should not be more than half ripened, with the sap flowing freely, so that the wood will lift easily from the bark. Use a sharp knife, and have lengths of raffia about 12 inches long in readiness for tying around the inserted buds. Propagation by layering can be done at the present time. Choose for this purpose moderate and firm growths that are not quite ripened. Bend the shoot, make an incision, and split up the stem about 3 inches. Remove the soil 3 inches deep or so, then peg the shoot into the hole firmly, and tie it to a neat stake, filling in around the split part with a compost of sandy soil, which should be made rather firm.

Wallflowers should be transplanted as soon as they are large enough to handle. When they have become established after the transplanting, pinch the tops from the plants, which will make them dwarf and of bushy habit.

Cyclamen hederifolium.—The seed of this will soon be ripe. Cyclamen seed is best sown when freshly gathered, so prepare pans containing a light compost and place them in a shady frame.

English Iris.—If beds of these have become overcrowded or the bulbs are too near the surface they should be lifted when ripe, replanting them in light, rich, sandy soil, in a position that is fully exposed to the sun yet is sheltered from strong winds and is well drained.

APPOINTMENTS FOR AUGUST.

JULY 31 to	AUG. 15	{ National Horticultural Exhibition at Bruges, Belgium.
TUESDAY,	AUG. 1	{ Royal Horticultural Society's Committees Meet.
WEDNESDAY,	AUG. 2	{ Midland Carnation and Picotee Society's Show at Birmingham (2 days). Chesterfield Horticultural Society's Show.
MONDAY,	AUG. 7	{ Bank Holiday. Basingstoke Horticultural Society's Exhibition. Dudley Horticultural Society's Exhibition. Seaham Harbour Horticultural Exhibition. Ramsey Horticultural Show (2 days).
TUESDAY,	AUG. 8	{ Flower Show in Abbey Park Leicester.
WEDNESDAY,	AUG. 9	{ Exmouth Horticultural Society's Show.
THURSDAY,	AUG. 10	{ Royal Botanic Society (Anniversary Meeting).
TUESDAY,	AUG. 15	{ Royal Horticultural Society's Committees Meet.
WEDNESDAY,	AUG. 16	{ Harpenden Horticultural Show Wilts Horticultural Society's Show.
THURSDAY,	AUG. 17	{ Taunton Deane Horticultural Society's Show.
SATURDAY,	AUG. 19	{ Sheffield Flower Show.
TUESDAY,	AUG. 22	{ Brighton Horticultural Society's Show (2 days).
WEDNESDAY,	AUG. 23	{ Shropshire Horticultural Society's Exhibition at Shrewsbury (2 days). Flower Show at Arundel.
THURSDAY,	AUG. 24	{ Aberdeen Flower Show (3 days).
SATURDAY,	AUG. 26	{ Hawick Flower Show.
TUESDAY,	AUG. 29	{ Royal Horticultural Society's Committees Meet.
WEDNESDAY,	AUG. 30	{ Bath Floral Fête.

SALES FOR THE WEEK.

TUESDAY, AUGUST 1—
Sale of the Lease and Goodwill, followed by the Stock of Seeds and Utensils in Trade re Jacob Wrench & Sons, Ltd. By Protheroe & Morris, on the Premises, 29, King William Street, E.C.

WEDNESDAY, AUGUST 2
219 cases of *Lilium Harrisii*, 9,000 *Freesias*, &c., at Protheroe & Morris' Rooms, 67 & 68, Cheapside, E.C., at 1 o'clock.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—63°2.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, July 26 (6 P.M.): Max. 85°; Min. 65°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, July 27 (10 A.M.): Bar., 30.1; Temp., 75°. Weather—Dull.

PROVINCES.—Wednesday, July 26 (6 P.M.): Max. 78°, Guildford; Min. 67°, N. of Ireland.

The Fruit-Growing Industry.

FOR many years the desirability of making an exhaustive inquiry into the conditions and prospects of the fruit-growing industry has been widely recognised. Some time since a well-considered scheme for such an investigation was set out by an organisation concerned in the promotion of fruit-culture, which was warmly supported by a few large landowners, amongst whom a former Duke of Bedford was prominent. The funds required, however, for a private enquiry were necessarily large, and a sufficient sum could not be raised to carry out the work efficiently, and it was in consequence dropped.

The Committee appointed by Lord Onslow in December, 1903, "to inquire into and report upon the present position of fruit culture in Great Britain, and to consider whether any further measures might with advantage be taken for its promotion and encouragement," have completed a very important task, and appear to have performed their work in a thoroughly satisfactory manner. The Report recently

issued (to which reference has been previously made) is practically a summary of the evidence taken, of the conclusions arrived at, together with the recommendations made by the Committee. Whether the full Report, including the questions and answers, will be published later is not stated; but it is very desirable that this should be issued, as much additional information would be afforded.

Some care seems to have been exercised in the selection of representative and independent witnesses, though the number might have been extended with great advantage by the inclusion of some ten or twelve exceptionally qualified men, who appear to have been strangely overlooked.

In the course of an investigation like this omissions must inevitably occur, but it is remarkable that no cognisance whatever has been taken of the effects upon the fruit industry of climatal variability. Yet the growers' returns, the market rates, and the whole aspect of the fruit-growing question must depend ultimately upon this. Perhaps it was considered as outside the work of the Committee because no remedy could be suggested, but it has a most important bearing upon the prospects of the industry and the limits within which extension is desirable or likely to yield reliable returns. In this connection the annual returns of the fruit crops in Great Britain, which have been published by the *Gardeners' Chronicle* for over forty years, with the expenditure of much labour and money, would have furnished important information that would have well repaid careful analysis. These also have been quite ignored by the Committee, though every matter bearing upon their inquiry should at least have had some consideration. The report for the present year is given in the current issue (see pp. 82—87).

Insufficient attention has been paid to the fact that a large portion of modern commercial fruit-growing is only a part of highly developed market-gardening, and the more generally the cultivator works upon this plan the better the average results. Ample proof could have been afforded of this in some of the districts visited by the Committee, and many of the most successful growers would refer their success mainly to having early learnt the imprudence of having "all their eggs in one basket." Intensive cultivation—i.e., the best form of market gardening or market farming, including as much fruit as can be safely and satisfactorily depended upon—is giving by far the largest returns from the land at the present time, and is most promising for the future. We cannot, therefore, help regarding it as a mistake on the part of the Committee that these points have not been adequately dealt with.

Turning to the Report it will only be possible to glance at the inquiry in a general way, as a full discussion would require more space than can be spared here. It is estimated that the total area under fruit in Great Britain does not exceed three hundred thousand acres, but "it is not possible to obtain absolutely accurate figures," partly because there has been a strange overlapping in the returns collected by the Board of Agriculture, and no account is taken of any orchards in holdings of less than 1 acre. The progress of the industry as shown by the increased acreage under fruits in recent

years is especially referred to, orchards having increased from 148,221 acres in 1873 to 243,008 acres in 1904; while small fruits have advanced from 69,792 acres in 1897 to 77,947 acres in 1904. This is an increase of 43.9 per cent. for thirty-one years in the case of orchards, and 11.7 per cent. for seven years as regards small fruits. During the corresponding period nearly all ordinary farm crops show a great decrease in area; the Wheat acreage, for instance, has fallen no less than 46.3 per cent. in sixteen years; and this fact has induced the Committee to state that fruit culture "is the only form of agriculture which has exhibited any sign of progress in recent years."

The increasing demand for fruit both in a fresh and in a preserved state was well established by the examination of several witnesses, some being experienced jam-makers. There was also a general consensus of opinion that fruit growing could be still further extended with advantage. Several very able cultivators, however, strongly urged cautious advance, and one witness appropriately pointed out that on a large area recently planted with fruit-trees the full bearing stage has not yet been reached.

As regards the improved value of land under fruit, both in rental and for sale, there can be no question, and ample evidence was given upon this point, also as showing the increased labour required in districts where fruit-culture has become an important part of the local industry. Reference was further made to the additional labour demanded for cider-making, jam-making, and basket-making, all of which are connected with the fruit trade; and the evidence tends to show that within judicious limits the extension of fruit-growing results in general benefit to the country.

In summarising the difficulties and drawbacks of the industry, the Committee classified the chief alleged disadvantages as follows:

I. Insufficiency of knowledge in regard to—

- (a) The right kinds and varieties of fruit to plant.
- (b) The character of the soil, and the effect of manuring.
- (c) The pruning and the general treatment of fruit-trees.
- (d) Diseases and insect-pests, and the methods of combating them.
- (e) Packing and grading.

II. Land tenure, especially the difficulty of obtaining land for the cultivation of fruit, and of adjusting equitably the respective interests of landlord and tenant.

III. Taxation grievances.

IV. Railway grievances.

V. Foreign competition and tariffs hostile to British fruit.

VI. The insufficient inspection of fruit, especially of foreign fruit.

VII. The difficulty of obtaining labour in country districts.

VIII. The insufficiency of markets.

IX. The ravages of birds.

X. The effect of the rise of price in sugar on the jam industry.

Under each of these heads a good deal of evidence was taken, much of which is open to considerable discussion or requires fuller explanation than is afforded in the Report to hand. As regards the first, want of knowledge is most marked in the case of diseases

LILIUM SUTCHUENENSE, A NEWLY-INTRODUCED LILY FROM CHINA: FLOWERS ORANGE-COLOURED WITH PURPLISH SPOTS.

and insect pests, packing and grading, and upon a point not mentioned, namely, the selection of suitable sites for fruit trees, which is quite distinct from the soil question. Reference is made to the work done by horticultural instructors under county councils and to various colleges and institutions, but though the Committee state they are "most anxious not to disparage any of the good work which has been accomplished so far," it does not seem that they give full credit to the efforts made by this and other journals, long before the County Councils came into existence, and to the lecturers and instructors who in many instances are highly qualified men who have performed most useful work.

It is recommended that a sub-department of the Board of Agriculture be formed to deal with horticulture and pomology, and it is most earnestly hoped it will lead to due action being taken in that direction. It is intended to perform a twofold service, first, as a bureau of information and an intelligence department; second, that an experimental fruit station should be established for research, with perhaps a demonstration farm in addition. Both the latter would be used as training establishments.

The whole scheme is commendable in its inception and principles, but a large part of its usefulness to fruit-growers and horticulturists will depend upon how it is developed and upon the capabilities of those who are entrusted with the task. A broad-minded appreciation of the requirements of cultivators, combined with thorough practical as well as scientific knowledge, is essential.

Under land-tenure the Committee rightly consider that every facility should be afforded for fruit-growers (on a small scale especially) to become the owners of the land planted; and on the question of valuation for tenants they express strong approval of the Evesham custom. In this system the incoming tenant pays a valuation to the outgoing tenant, and the landlord is only concerned in ascertaining that the new tenant is a reliable man. As a matter of fact the right of refusal is rarely acted upon.

As regards taxation it is especially suggested that the assessment of fruit-land for local rates should not be increased for five years from the time of planting in the case of small fruits, for seven years in the case of a mixed plantation, and for twelve years in the case of orchards, an equitable plan for assisting the fruit-grower to recover from the outlay necessitated in fruit planting. In reference to glass-houses it is also suggested that the allowance for repairs and depreciation, as concerns the income-tax rebate, should be increased from one-sixth to one-third, and the Committee further recommend that the "Agricultural Rates Act should be amended so that in future glasshouses used for commercial purposes may for the purpose of that Act be held to be land and not 'buildings.'"

Much evidence was taken upon the railway grievances which would require considerable space to deal with in detail. One point of some importance is the suggestion that owner's risk rate should be abolished, an increase of 5 per cent. on the present charges being considered a fair amount to bring it within the Company's risk. If, however, that is not done, it is considered that the

words "culpable negligence" should be substituted for "wilful misconduct" in the conditions as affecting the Company's servants. In view of the combination amongst railway companies, it is considered that an official or a department should be entrusted with the duty of watching over the companies' actions, and to report to Parliament accordingly.

The foreign tariffs, the inspection of foreign fruits, the labour difficulty, the question of increasing markets, and the ravages of birds, all bring out various subjects of interest and importance, but sufficient has been said to indicate the general scope of the Report. It will be remembered that the suggestions made are recommendations only. Unless the Board of Agriculture itself or some influential outside action be taken, the whole work of the Committee, as is often the case in such circumstances, will remain as a dead letter. Horticulturists and fruit-growers generally should therefore express their views fully and freely, and endeavour to bring some pressure to bear upon the completion of the work.

FRUIT CULTURE.—According to the Report on the Agricultural Returns for 1904, just published, the total area of land utilised for small fruit-culture in England was 70,612 acres, Kent heading the list with 22,519 acres, no other county having as much as 5,000 acres. The total area in England used for orchards was 236,705 acres, of which Kent occupied 29,055 acres; Hereford, 28,042; Devon, 27,316; Somerset, 25,265; Worcester, 22,387; Gloucester, 20,385; all the other counties having a very much smaller acreage under orchard culture. Scotland had 6,072 acres devoted to fruit-culture, and 2,490 acres to orchards.

IMPORTS OF FRUIT.—Some reductions appear in the imports of fruit in 1904, the two largest items—Oranges, and more especially Apples coming to our shores in diminished quantities. Grapes, Pears, and Cherries were nevertheless largely increased, the quantity of the two latter being twice that of 1903. All three were the highest since they have been returned in their present form by weight, instead of, as formerly, in measure. The heavy importation of Potatoes in 1903 was still further increased in 1904, and the total amount was only just short of half a million tons. Nearly half of these imports are credited to France, while Germany and Belgium together only make up three-fourths of the French total. Onions were also imported in very large quantity, although not quite reaching the total of 1903.

WOBURN EXPERIMENTAL FRUIT FARM.—A copy of the fifth report issued by the Duke of BEDFORD, K.G., and Mr. SPENCER PICKERING has been issued, and may be obtained from Messrs. EYRE & SPOTTISWOODE. The report deals especially with the results of observations made during the last ten years on the growth of Apple-trees, the effects of pruning, replanting, various methods of planting, watering, manuring, and many other points which are elaborated with much detail, and will demand further notice on our part later on. We can here only state that if the results of these experiments be confirmed elsewhere, fruit-growers must considerably modify their present notions as to the relative advantages of pruning, pinching, thinning the fruit, careful as opposed to careless planting, and so forth. Elaborate as are the experiments and the records relating to them, it is obvious that they must be repeated on a large scale in many different localities before accurate general conclusions can be drawn.

LILIUM SUTCHUENENSE? (see Supplementary Illustration).—This beautiful Lily of the Martagon section is a native of the Chinese province of Sutchuen, and was exhibited by Messrs. JAMES VEITCH & SONS, of Chelsea, at a recent meeting of the Royal Horticultural Society. It was originally introduced by M. MAURICE DE VILMORIN, and was shown among several other novelties introduced by Mr. E. H. WILSON. The narrow, almost linear leaves are spirally disposed, and closely approximate. The perianth segments are strongly recurved, deep orange with purplish spots. The plant was figured in the *Botanical Magazine*, t. 7715, and, judging from specimens from Messrs. VEITCH, is subject to considerable variation in stature, degree of branching, and size of flowers. It is nearly allied to *L. tenuifolia*.

THE MIDLAND CARNATION SHOW, will, we may remind our readers, be held in Edgbaston Botanic Gardens, Birmingham, on Wednesday and Thursday next, August 2 and 3. The Secretary and Treasurer is Mr. T. HUMPHREYS, Botanic Gardens, Edgbaston.

HOLLAND PARK AND THE WEST LONDON HOSPITAL.—On behalf of the Ladies' Association who are working in aid of the new casualty ward at the West London Hospital, the gardens at Holland House will be opened to the public, by permission of Lord and Lady ILCHESTER, on Saturday, July 29, from 2 to 5 P.M., on payment of 2s. 6d. each, and from 5 to 8 P.M., on payment of 1s. each. The Irish Guards' Band will play, and tea will be sold at 6d. per head.

COREOPSIS.—In Composites in general the outer florets, florets of the ray, as they are called, are flat and strap-shaped, whilst those of the disc are less conspicuous and regularly tubular. In a *Coreopsis* just brought under our notice the ordinarily flat or ligulate florets are developed in a tubular fashion, and are quite sterile, thus resembling the outer florets of *Centaurea*.

NATIONAL POTATO SOCIETY.—We are informed that, on the invitation of Professor MIDDLETON, Director of the Cambridge University Agricultural experiments, the National Potato Society will inspect the Potato trials at Impington, near Cambridge (Iliston Station), on Friday, August 4. Members who would like to be present and would travel from London are requested to communicate with the Secretary, Mr. WALTER P. WRIGHT, Postling, Hythe, in order that a special fare may be applied for. The Society's trials at Reading may be inspected on Wednesday, August 2. Visitors should communicate with Professor PERCIVAL, University College, Reading.

HORTICULTURAL CLUB.—About seventy members and friends visited the Wisley Gardens on Thursday, July 20, and spent an enjoyable hour in this Surrey woodland. The party was conveyed by special saloon carriages to Weybridge, where brakes were in readiness for the drive to Wisley. After an inspection of the Royal Horticultural Society's garden, lunch was served at the Hut Hotel. The drive was resumed through beautiful lanes to Chertsey, where a launch was waiting to continue the journey to Kingston. Here brakes were again in readiness to take the party, at the kind invitation of Mr. JAMES WALKER, to his charming garden on Ham Common. The magnificent fruit-houses were inspected, and a delightful hour spent in the grounds, where refreshments were provided. There were several guests, among them Mr. ARDERNE from South Africa. Among those present were Mr. H. J. VEITCH and Mrs. VEITCH, Mr. ARTHUR SUTTON, Mr. W. A. BILNEY (who was heartily thanked for his kindness in helping forward the arrangements), Mr. H. P. MAY, Mr. GEO. MONRO, Mr. A. WATKINS, Mr. G. INGRAM, Mr. G. GORDON, and Mr. ASBEE.

* *Lilium sutchuense*, FRÉCHET in MOROT, *Journal de Botanique* vi. (1892), p. 318.

VISIT TO MONIFIETH NURSERIES.—In the *Dundee Courier* for July 24 appeared a description of a visit of inspection from agriculturists and others to the nurseries of Messrs. W. P. LAIRD & SINCLAIR, Ltd., Monifieth, near Dundee. We are informed that the newest varieties of Potatoes to the number of forty are being tested there this year. Golden Wonder, Highlander, Conquering Hero, Eldorado, Sim Gray, Pearl, Diamond, Money Maker, Duchess of Cornwall, and many other well-known varieties are making fine growth and looking well. Mr. COLIN MACPHERSON'S three new varieties, introduced by this firm last year, namely, The MacPherson, New Victoria, and Early Champion, are said to be looking well.

ACCIDENT TO MR. GEORGE CUTHBERT.—Those of our readers who know the very kindly disposition of Mr. GEORGE CUTHBERT, Sen., head of the firm of R. & G. CUTHBERT, nurserymen, Southgate, will hear with great regret that he sustained a very serious accident on the 24th inst. While attempting to stop a runaway horse and van which had been unloading at the premises, Mr. CUTHBERT was knocked down, and his foot being caught in the front wheel, was dragged for a distance of about 25 yards, and frequently dashed against the kerbing of the path. Though Mr. CUTHBERT'S clothes were torn to pieces, no bones were broken, but the shock is naturally a very severe one. The condition of the patient is described as being as good as could be expected.

"BRITISH TREES."—Messrs. HUTCHINSON & Co. are bringing out in fortnightly parts a book bearing this title. The trees are drawn and described by REX VICAT COLE. The work is beautifully illustrated and well got up. Artists often see plants with very different eyes from botanists, hence it is not at all uncommon for an artistic representation to be unrecognisable from a botanical point of view. This cannot be said of Mr. VICAT COLE'S drawings. The landscape views are delightful, and the botanical details so accurately rendered as to satisfy the most fastidious. The text is similarly correct, though in his desire to avoid technicalities the author has often to employ a sentence where a word or two would suffice. It is not the people who really seek information and knowledge that object to scientific phraseology. The student soon gets accustomed to it and recognises its necessity. The present part is concerned solely with the common Ash; its varieties are not mentioned.

ROYAL BOTANIC SOCIETY.—Considerable difference of opinion exists amongst the Fellows as to the expediency of accepting, as a means of improving the financial position of the Society, the pending proposal of the Council to increase the Fellows' annual subscription from 2 to 3 gs. In many quarters it is thought that this proposal will, if carried, make the position worse, and that the necessity for such a change would not exist if more popular methods of management were adopted. Several Fellows who hold this view intend to support a resolution for the appointment of a committee of inquiry, which will be moved by Mr. J. S. RUBINSTEIN at the Fellows' meeting to be held in the Gardens at 4.45 on Friday, July 28. We cannot chronicle the result till next week.

SALVIA DICHROA has afforded a splendid spectacle with Mr. FITZHERBERT at King's Wear. It is over 8 feet high, with hundreds of flower-spikes.

"THE ART OF CONSERVING," by VERA GALWAY. (JOHN & ED. BUMPUS, LTD., Oxford Street, W.)—Viscountess GALWAY has filled a little book about conserving fruits and vegetables

that should prove useful to all who wish to accept her offer and have Plum-tart at Christmas and Raspberries-and-cream in March. The apparatus recommended is a German one, made by one Herr LEONHARD, and known by him as a Frisc-balter. Briefly, it is a scheme for sealing fruits, &c., in closely sealed jars and Pasteurising it. Viscountess GALWAY remarks that the excellent bottled vegetables procurable abroad are prepared when the vegetables are young. She adds: "I am assured that most of the Peas are preserved at Metz, which is the great Pea-growing centre. We are much too fond of large vegetables, and until we cultivate the small French vegetables, such as Carrots the length of one's finger, and the small soft Pea and delicate French Bean, I fear our efforts in vegetable conserving will be not all successful, as it is impossible to kill the germ without otherwise boiling the Pea." Apart from the last sentence we agree with these remarks; English market growers too often sacrifice quality to quantity. The recipes seem excellent, and have been tested by the writer; but the translator is not always sufficiently careful as to grammar. We read everywhere here of litres and grammes, and only find the British cook's equivalent for them in one place, yet the reading of a Centigrade thermometer is always translated into Fahrenheit. It must not be overlooked that the preservation of certain fish and savories is also mentioned in this little book.

IMPATIENS HOLSTII is doing well in the open-air with Mr. GUMBLETON at Queenstown.

SIR EDMUND LODER'S GARDEN at Leonardslee, Horsham, Sussex, is a most interesting one, and contains many tender species which Sir EDMUND has succeeded in acclimatising there. Our correspondent Mr. W. A. COOK, late gardener at Shirley Park, Croydon, has been appointed to take charge of Sir EDMUND'S garden as from July 12.

THE FARADAY HOUSE JOURNAL.—This is the official publication of the Electrical Standardising, Testing, and Training Institution known as Faraday House. The July number of the Journal chronicles the moving of the Association into larger and more convenient premises in Southampton Row, and it contains pictures of the old and of the new Faraday House, and portraits of the members of the Board of Control.

GARDEN CITY ASSOCIATION.—We learn from *The Garden City*, which is the official organ of the Association of that name, that an exhibition of Cheap Cottages was to be held in Garden City. The cottages were to be such as are most appropriate for the housing of garden citizens. The DUKE of DEVONSHIRE opened the Exhibition on July 25. Detailed information on the subject is to be obtained from the Secretary, Mr. W. COOPER, 347, Birkbeck Bank Chambers, Holborn, W.C.

TURNIP-SEED CASE.—Mr. Justice BUCKNILL has recently given judgment in a case where a farmer brought an action against a firm of seedsmen for breach of contract in supplying the plaintiff with something that was not what he expected it to be. The seedsmen relied on the now familiar exemption clause in their invoices, and the judge found in their favour with costs. The case was one of "sporting," which, as everyone knows, is very common among Brassicaceous plants. It by no means follows that the seedsmen are to blame in such cases, for, as a general rule, they exercise great caution to prevent accidental admixture. Their reputation is at stake, and the fierce competition that now exists is a great safeguard to the purchaser. Whether the "sport" in this case originated from accidental cross-breeding, from reversion, or natural varia-

tion, was beyond the power of the judge to decide, but, at any rate, he has absolved the seedsmen from responsibility in the matter.

PUBLICATIONS RECEIVED.—*Annual Report on the Government Cinchona Plantation and Factory in Bengal, for the year 1903-4*, by Colonel Prain, I.M.S. There has been an increased out-turn of quinine and cinchonidine, but less cinchona febrifuge was required than in the previous year.—*Annual Report of the Royal Botanic Garden, Calcutta, for 1904-5*. Among the chief out-door works of the year were the deepening of several of the tanks, and alterations in the gardens. Colonel Prain and Mr. Drummond completed their investigations into the species of Agaves. The herbarium is greatly improved by the addition of new cabinets, and the library has also been enlarged. It is desirable that the botanic staff should be increased, as the work becomes increasingly heavy.

NEW OR NOTEWORTHY PLANTS.

STANHOPEA DEVONIENSIS, LINDL.

A NATURAL HYBRID?

I HAVE received from Mr. P. Wolter, Magdeburg, our zealous and skilful German hybridist, the flower of a Stanhopea he has raised by crossing *S. tigrina*, Lindl. × *S. insignis*, Frost. Unfortunately he does not remember which was the seed-bearing plant, but he is quite sure of the plants themselves and of the correctness of the names. I was highly astonished to find that the hybrid is exactly and in every respect like the Duke of Devonshire's Stanhopea, figured more than sixty years ago by J. Lindley in his *Sertum Orchidaceum*, Plate I. In this figure the blade or epichilium had an undivided apex, whilst it is in fact three-pointed, an error already pointed out by Reichenbach in the *Xenia Orchidacea*, L., p. 119 (and repeated in Walper's *Annales*, VI., p. 586). It is remarkable that already Dr. Lindley was astonished at the close resemblance of *S. devoniensis* with the two other species (the supposed parents). In his valuable work *Folia Orchidacea*, Pt. I. (Stanhopea), he adds to the Latin text some interesting remarks. He says: "Resembles *S. tigrina*, from which it is distinguished by the slightly divided epichil and almost wingless column. To *S. insignis* it approaches in form, although so different in colour; but the hypochil is very deep, broader than long, and prominent in front instead of being pressed backwards. The flowers are extremely sweet-scented, yellow with deep crimson blotches; the lip is white with a few spots here and there, and a deep purple stain over half the hypochil. . . . I am indebted to General Doreier for a variety with a deep blood-red hypochil, said to come from Guatemala." Thus Dr. Lindley's text, and I have nothing to add to this masterpiece of description.

The native country of *S. tigrina* is without any doubt Mexico, where this striking plant already in olden times of Montezuma had the tongue-breaking name "Coatzonte Coxoahitl," and also for *S. devoniensis* the Central American source is stated, but *S. insignis* is of doubtful origin. From the days of *Botanical Register* until our days, Brazil is said to be the native country, but even Dr. Cogniaux, the author of the most recent and exhaustive monograph of Brazilian Orchids, says, "Habitat in Brasilia, loco haud indicato" ("Grows in Brazil, but nobody knows the place"), and he cited Loddiges, the author of the *Botanic Register*, and M. Gaudichand, as authorities for his statement. Moreover the habitat "Brazil" is extremely vague and quite worthless. Other authorities declare the plant to be a native of the Peruvian Andes, but Lindley asserts, in the *Folia Orchid.*, l.c., p. 7, that the Peruvian plant is not *S. insignis*, but *S. Bucephalus*. Under these circumstances, and considering the well-known carelessness of early collectors and importers in respect to the habitat.

of their plants, it is not impossible that *S. insignis* is a native of Central America. The amount of doubtful notes about the native habitats of *Stanhopeas* cannot be better illustrated than by the fact that of twenty-three species quoted by Reichenbach in the sixth volume of Walper's *Annales*, no fewer than nine are of uncertain origin. "Allata esse dicitur e Mexico," "Brasilia," "Guatemala," and other similar notes occur very often. After all, the flower at hand is so exactly similar to the typical *S. devoniensis* that the most hair-splitting description cannot show any real difference, and we are indebted to Mr. P. Wolter for this unintentional but nevertheless very interesting result of his efforts. *Dr. Kranlin, Berlin.*

attached, and in summer whole streets of fore-courts are gay with flowers.

It is only within comparatively recent years that the Corporation of Norwich has taken up public gardening. The principal of the city gardens is Chapel Field. It is a spacious triangular enclosure containing five avenues of Elms and Limes. Formerly a dismal waste, it was railed-in about 1866, but no attempt was made to cultivate it until about a quarter of a century ago, when it was re-turfed, flower-beds were formed and shrubs planted, and it was then used as a public park. For some years the gardening work was put out to tender, and the contractor had also charge of the Castle gardens, taken over by the city upon the discontinuance

appointment was conferred upon Mr. James Ward. Under that gentleman's management a great improvement has already been effected in all the parks and gardens.

Chapel Field, the most popular as well as the most important of the public gardens of Norwich, has never been more beautiful. From early spring to late summer there is a remarkably brilliant display of flowers. There is no carpet-bedding in the gardens, but some 28,000 plants are used, and every variety is systematically labelled with its popular name, its order, and habitat. Last autumn extensive work was carried out in the formation of new beds, the re-edging of walks, and other improvements which will greatly tend to the development of the gardens.

FIG. 31.—VIEW IN THE CHAPEL FIELD GARDENS, NORWICH.

NORWICH PUBLIC GARDENS.

Norwich has long been known as "The City of Gardens," and the distinction is not altogether misapplied. Evelyn, who visited it in October, 1671, says, "The suburbs are large, the prospects sweet, with other amenities, not omitting the flower gardens, in which all the inhabitants excel." The city covers a very extended area, and behind many of the residences, even in the main streets, there are fine pleasaunces which, all unknown to the crowds who throng the thoroughfares, are laid out in quaint old-fashioned style. Every suburban villa has its garden, and there are at least half a dozen residences within fifteen minutes' walk of the city which stand in park-like grounds. Many artisans' dwellings have garden-ground

of the Castle as the county prison. Then, through the action of the Norwich Playing-fields and Open-spaces Committee, other areas were transferred to the Corporation, including four churchyards which have been transformed into gardens, and last year, through the munificence of a private individual, an additional pleasure-ground, the Woodlands Park, passed into their keeping.

To the north-east of the city is Mousehold Heath, of 300 acres, which has been planted with trees and shrubs, and intersected with rural walks and roads. Minor places of public resort are Waterloo Park and Gildencroft Gardens.

Rather more than two years ago the Corporation, in consequence of the great extension of this part of their public work, decided to discontinue the contract system, and placed the whole of the gardens under a Parks Superintendent. The

The Castle gardens are situate in what was the moat of the ancient stronghold. The Castle itself has been converted into a museum, and its precincts laid out as a garden. Upwards of 10,000 plants are planted out in the Castle and museum gardens. At Waterloo Park 30,000 Wallflowers are planted for flowering in spring, and the extent of the work in the other gardens, &c., may be estimated from the following figures: Gildencroft and St. Augustine's Churchyard, 12,000 plants; Haymarket (open space), 1,860; Isolation Hospital Grounds and Garden, 7,000; St. John de Sepulchre Churchyard, 5,000; St. Clement's Churchyard, 4,500; St. Saviour's Churchyard, 3,000. The pot plants at the cab shelters, the plants in the shrubberies at Prince of Wales' Road, St. Catherine's Plain, and St. Andrew's Hall Plain, brings the total number

to 104,560. Mr. Ward also has the superintendence of the Norwich Officials' bowling-green, the Riverside Road slopes, the Carrow Bridge Garden, and the Corporation Nurseries.

Norwich has the unenviable reputation of being one of the most heavily rated municipalities in the United Kingdom, but the citizens do not object to the increased expenditure involved by the development of its public gardens, and probably no work is more appreciated than that of the Parks Superintendent. *Correspondent.*

FUNKIAS.

As hardy border plants or in appropriate corners of the rockery, there are few finer subjects than the Funkias, and among them the finest is *F. Sieboldi* (fig. 32). The bold glaucous foliage and the conspicuous fragrant pale lilac blossoms are most attractive. No special cultivation is required; but it must be remembered that snails appreciate the plant as much as we do. In our own experience we have found it difficult to keep the Funkias to ourselves. For the photograph we are indebted to Miss Wallace, of Ardnamore, Donegal.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from p. 65.)

May 8. — To-day's journey was through new country to me, my highest point hitherto having been the Hsin-Luog-Tan. The country in some respects resembled that around Ichang, the hills having the same pyramidal shape. Forts or redoubts were common, crowning the tops of the higher hills. These date back to the time of the Taiping disturbance.

The character of the flora began to change somewhat. I gathered several fresh plants to-day, including—

Houttuynia cordata, *Lysimachia Henryi*, *Ligustrum sinense*, *Saxifraga sarmentosa*, *Catalpa Fampferi*, *Populus adenopoda*, *Bischofia javanica*, and *Koelreuteria bipinnata*.

This was the first time I have seen the *Koelreuteria* in the actual Yang-tsze valley, and the same remark applies to the *Bischofia*. The latter grows to a large size, and is known as the "Wu-yang" amongst the Chinese. The wood is soft and of little value.

I also noted a Euphorbiaceous tree allied to *Sapium* which was quite new to me. Its bright orange-coloured leaves made it conspicuous; these were the old leaves about to be replaced by new ones. It only grows 10 to 15 feet high. Its seeds are used medicinally in cases of diarrhoea. It is the "Pa-tou" tree of the Chinese. *Deutzia scabra* was very common to-day on the cliffs. *Cupressus funebris* was particularly abundant, giving the hillside the appearance of being well wooded. Clumps of small Pines occurred at intervals.

Silkworm raising is a common industry. I looked into one house where there were thousands of the worms in large trays being fed. The room was frightfully stuffy and the air foul. I very quickly made my exit. The worms were fed on the leaves of the Mulberry (*Morus alba*), which by the way has black fruits hereabouts. These fruits are much smaller than those of *Morus nigra*, but quite equal to them in flavour.

We encountered no rapids of any consequence to-day, and made good progress—30 miles. We moored for the night about 12 miles below Wan Hsien. The day was the hottest we have had so far; at 3 P.M. it was 87° F. in my cabin. The crew rested for a couple of hours after noon on account of the fierce sun.

May 9. — We made our usual early start; reached the city of Wan at 2.30 P.M., and moored well above the town. Near the east end of the city the river takes a bend almost at right-angles. The left bank is strewn with huge boulders, and the right is a sloping shingle-bank. Wan is unquestionably the most beautiful city on the Yang-tsze, being picturesquely situated on the sides and summits of a number of hills arranged in a half-circle. Many Banyan and other trees give it a peaceful air, and the number of junks moored here testify to its great commercial importance. Several fine pagodas built on lofty eminences ensure good luck for the town. The hill-sides around are all highly cultivated, and in March are one mass of yellow "Rape." Of this so-called "Rape" there are two distinct kinds—one with lyrate, and the other with amplexicaul leaves,

It is undoubtedly one of the most valuable timbers in Central and Western China. The tree is exceedingly common from Ichang westward, both in the immediate vicinity of the river and on the mountains north and south up to 3,000 feet altitude. Its handsome appearance is well deserving of Fortune's eulogy (see *Gardeners' Chronicle*, 1880, p. 228). This Cypress deserves the attention of the authorities of the Hong Kong Botanic Gardens in particular for planting in the new territory of Kowloon; and not only ought it to be largely planted there, but in other of our colonies with a warm temperate or sub-tropical climate. Not only is the timber valuable for boat-building, but also for house-building and general carpentry. *Cupressus funebris* is certainly one of the handsomest and most useful of all the Asiatic Conifers.

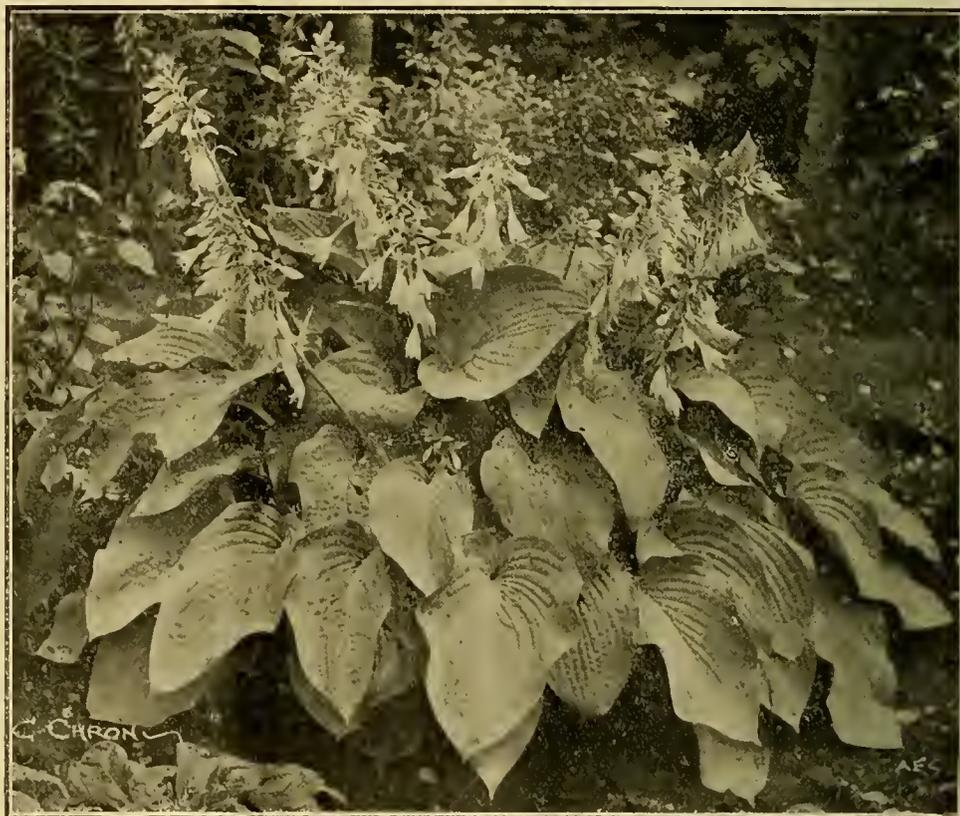

FIG. 32.—FUNKIA SIEBOLDI, FROM A DONEGAL GARDEN.

called respectively the "great" and "little" Rape. The latter is the earliest and less grown of the two. Wan is considered halfway to Chungking, and a feed of pork for the crew is the usual custom. I had hoped to get a little further to-day, but the Fates in the shape of the crew willed otherwise, and I was forced to be content to remain here till the following day.

Here our useful little lifeboat left us and returned to Ichang. The crew of this boat were good-natured and obliging, and went about their work in a quiet and businesslike manner, a pleasant contrast to the crew of my boat, who were for ever shouting or quarrelling. I gave them the customary present of silver, and they seemed very well pleased.

Close to where we were moored the people were busy building boats. With the exception of a few slabs of Oak-wood athwartships, these boats are built entirely from the timber of *Cupressus funebris*. The timber, which is very close-grained, is known as "Peh-mu," "White-wood."

Planted near some graves I noted several trees of what I take to be the *Thuja plicata*, mentioned by Dr. Masters in the *Index Florae Sinensis* (*Journal of the Linnean Society*), vol. xxvi, p. 540.

The only fresh plants to-day were *Thalictrum minus* var., *Scutellaria rivularis*, and *Lonicera affinis*. The Honeysuckle is near *L. japonica*, but differs in having glabrous leaves and more slender flowers in much larger corymbs. I only saw one plant trailing over a cliff.

Pears and Plum trees are common around Wan. Loquats were ripe, and we bought some excellent Cherries. The crops continued to be the same as those already mentioned, and sun was badly needed to harvest them. Owing to the long-continued rain the officials have forbidden the killing of flesh or fowl and the capturing of fish, in order to appease the angry god. Thus we were unable to replenish our larder, though we were badly in need of supplies. The pork for the crew was obtained surreptitiously under cover of night.

(To be continued.)

THE METFORD LEMON.

On a former occasion we had an opportunity of figuring the fruit of this variety, remarkable for its large size (see *Gardeners' Chronicle*, April 28, 1900, p. 267). That it is also worthy of notice as a decorative plant for the conservatory is shown by our illustration (fig. 33) of the tree as growing in the temperate-house at Kew. The photograph was obligingly forwarded to us by Mr. C. P. Raffill.

teristic mottling of *C. Chamberlainianum*. The flowers are produced in succession; the scape is erect, 1 foot to 15 inches in height, and densely covered with whitish hairs. The dorsal sepal is rounded in form, of a brownish-green in the centre, shading to a whitish-green at the edge. The petals are spreading, twisted, and almost linear, about 2 inches in length, with a distinct ciliate margin; the ground colour is white, which is densely blotched with red-brown. The pouch is rose-

more in length; the blade is cordate-acuminate in form, 1 foot to 18 inches in length. The inflorescence is borne on a stout, erect peduncle, 6 inches in height. The spathe is 6 inches long by 4 inches broad, of a dark brown-red colour on the inner surface, and densely marked all over with almost black linear markings; the outer surface of the spathe is deep green. The spadix is very thick, almost as long as the spathe, and of the same brown-red colour. The species was figured in the *Botanical Magazine*, t. 7242. *W. H.*

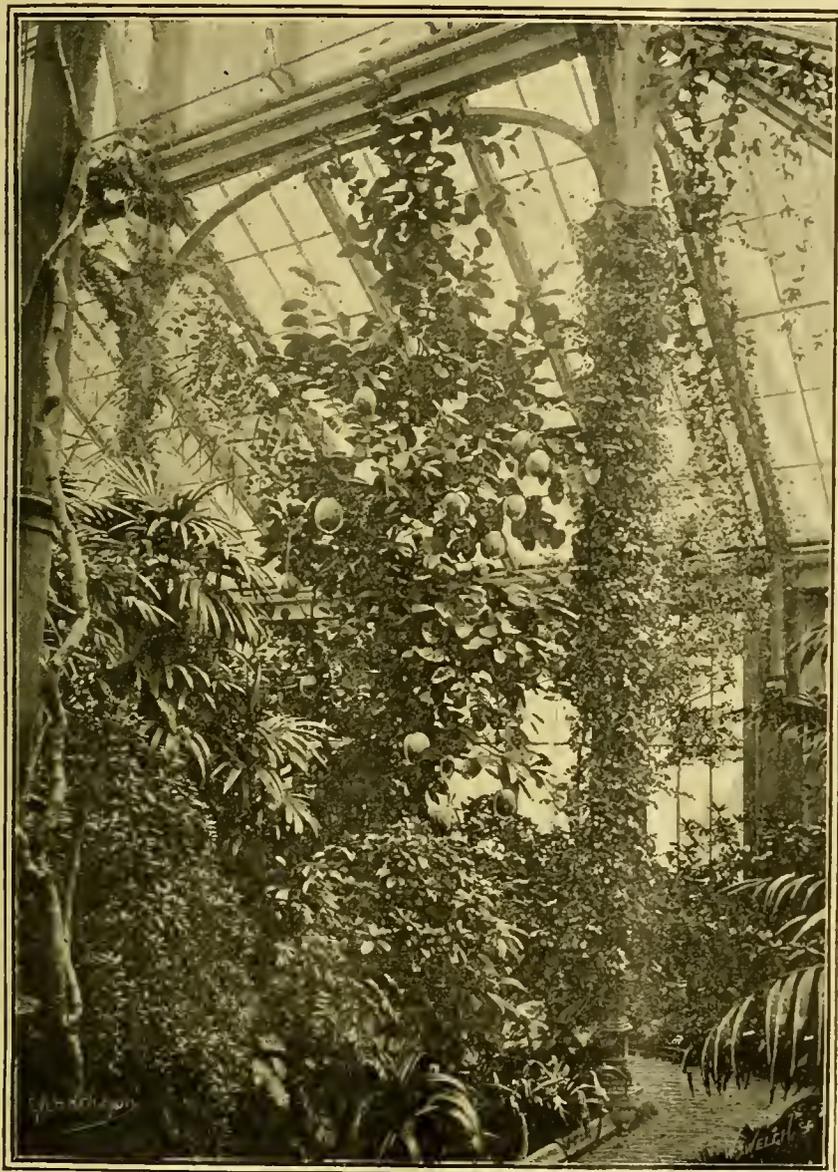

FIG. 33.—THE METFORD LEMON IN THE TEMPERATE-HOUSE OF THE ROYAL GARDENS, KEW.

KEW NOTES.

CYPRIPEDIUM GLAUCOPHYLLUM, *Smith*.—A plant of this recently-introduced species is now flowering in the Orchid-house. It is a native of Java, and was first discovered and described about five years ago. The Kew plant was obtained from Messrs. Sander & Sons, St. Albans, in the early part of the present year, and since that time it has grown vigorously, having all the appearance of being a strong, robust-growing species. It is allied to *C. Chamberlainianum*, which it resembles somewhat in general appearance, though it is totally distinct. The leaves are fleshy and distinctly glaucous, about 8 inches in length by 2½ inches in breadth, without any of the charac-

coloured at first, turning to violet-purple with age. A flower of this charming species is figured in the *Orchid Review* (fig. 44) for July of this year.

SYNDROSPADIX VERMITOXICUS, *Engler*.

This extraordinary Aroid is now in flower in the Begonia-house. It is a native of Tucuman, where the tubers are said to attain to a weight of 4 lb. They are very much like those of an *Amorphophallus*, except that they are rather more globular in form. In this genus the leaves and flowers are produced at the same time, not, as in some allied genera, wherein the leaf succeeds the inflorescence. The strong petiole is a foot or

NURSERY NOTES.

SWEET PEAS.

I was recently at Marks Tey, where Messrs. Dobbie & Co. have established a large seed-farm, and in the company of Mr. Cuthbertson, the head of this firm, I was much interested in all the various crops of seeds which were being grown. It was the Sweet Peas, however, that I went to see, and the sight of these was well worth the journey. More than four acres of ground are devoted to the culture of Sweet Peas for seed; but it was the trial-ground, where only a limited number of each sort was grown for trial, that interested me most. Mr. Cuthbertson pointed out to me that their aim was to supply seed as true to character as possible, and such as they were unable to grow themselves in the first year were given a trial before offering them to the public.

In the trial-ground it was proved beyond doubt that Countess Spencer was very sportive. In the rows of this variety there could be seen more variation than in any other sort, and probably several other varieties which have since been named have come from this parentage. Coming to Gladys Unwin, we found a slight variation here and there, but generally the stock was very true, and proves that this is a variety worthy of attention, for in addition to most stems producing four flowers on each, it is remarkably vigorous and free-flowering.

Coming to the standard varieties which have stood the test for market culture, I found Lady Grizel Hamilton very good; but I think that Miss Philbrick, which is similar, but of a still more pleasing shade, will supersede the older favourite, for as seen at Marks Tey it was certainly one of the best we have. Of the deeper shades, Hannah Dale was one of the best; it is a colour difficult to describe, for the deep purple has a peculiar tinge of red in it. D. R. Williamson is undoubtedly an improvement on Countess Cadogan. Orange Countess closely resembles the variety Helen Lewis, which gained a First-class Certificate and the Silver Medal of the National Sweet Pea Society this season. Mr. Cuthbertson has made some selections from the best varieties, and has already a decidedly improved form of Lord Rosebery, which is one of our best Sweet Peas. Other sorts are being looked after in the same way, and from what I saw when going round I feel there is no doubt that we may get better results from careful selection than from all the cross-breeding that can be done.

We already have too many varieties, but what we want is the best standard sorts kept up to their present standard, or improved upon, and it is only by careful selection that this can be done. I do not mean to say we could not find room for slightly varied shades of colour, but we must look for the best results from carefully weeding out all that show signs of deterioration, and saving the stock seed from the very best types of the various sorts. In my early experience of all seed-saving it was the practice to take a few of the very best plants for sowing, and while ensuring the best for ordinary sale we were keeping up the type, if not improving it, from year to year; and this is what is being done at Marks Tey. *A. H.*

GARDEN NOTES.

THE "BALLARDS," SHIRLEY, the residence of C. H. Goschen, Esq., is situated on the top of the far-famed Shirley and Addington Hills, and commands a splendid view of the surrounding country on the one side, and of London and its suburbs on the other. There is a kitchen and fruit garden of about 3 acres, situated on a south slope, surrounded by high walls, where some excellent crops are secured. Gardening is not carried out to such an extent as it was a few years ago, but some relics of the past show what has been accomplished. The pyramidal fruit-trees, Apple and Pear, are wonderfully good, and usually carry fine crops, this year being no exception. I noticed, fit to cut, some fine rows of Veitch's Extra Early Cauliflower, which were sown in March of the present season; excellent rows of Veitch's Criterion Pea, quite the best I have seen in the district, and a fine batch of Veitch's Golden Ball Lettuce. Over 1,000 plants of Royal Sovereign Strawberry are forced each year, and there is a good bed of plants in the open garden. Peaches and Nectarines and Grapes are looking well, especially a house of Muscat of Alexandria, which have been planted twenty-eight years, and have never failed to yield a good crop of fruits. Mr. Whittle, the present gardener, has had charge of the gardens for more than a quarter of a century. The lawns are well cared for, and on a gentle slope the shrubs and trees present a fine picture.

"HEATHFIELD," SHIRLEY.

This is the residence of H. Goschen, Esq. The gardening is principally outside gardening. All the lawns have nice slopes, and are dotted with flower-beds. Bulbs abound everywhere. A neat little rockery has recently been formed, which bids fair to add materially to the interest and beauty of the garden. The mansion is covered with climbers. There are some fine examples of Rambler Roses trained in different shapes. I noticed some very good Iris and *Chelone barbata* in the herbaceous borders, and a fine lot of *Chrysanthemums*.

In the kitchen-garden the crops were looking well, especially Potatoes and Asparagus. Several ever-flowering beds on the lawn are most useful. One bed contained mixed Tulips, Iris, *Lilium barbatum*, and *Tritoma Uvaria*, so that there is a constant show of flowers without having to rearrange the bed. An Ivy-covered arbour or tunnel is interesting. In the greenhouses were fine batches of *Gloxinias* and *Streptocarpus*, which flourish well under the care of the head gardener, Mr. Fry. W. A. Cook, *Leonardslee Gardens, Horsham*.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

CUCUMBER "SPOT."—I enclose for your inspection a few shoots of Cucumber plants having a few old leaves that had been affected with the "spot" disease and several young leaves made on the same shoots since the affected plants had been vaporised with sulphur on July 8. You will please observe that the young leaves are, so far as I can see, quite free from the disease, which in the case of affected plants during the two previous years attacked every young leaf as soon as it began to unfold. Thus it will be seen that the sulphur-vapour will not only prevent the "spot" disease from attacking Cucumber plants, but that it will also destroy the actual spot itself if applied in time. The house in which the "spot" appeared on the plants is 24 feet wide, and in addition to a row of plants set on ridges running parallel with the side walls, two rows of plants were planted in a ridge formed on the 4-foot-wide pathway, and trained up an X-shaped trellis, the top ends of the frame-work being screwed to the rafters, and the bottom ends let into the ground under the hot-water,

pipe on either side pathway. No. 14 galvanised wire was strained and fastened thereto, and the two rows of plants set anglewise in planting in order to afford mere space for training up the lower part of the sharp-angled trellis, which benefits equally by the morning and afternoon sun. Very little fire-heat was afforded this house, and after the trellises had been pretty well furnished and the plants showed signs of exhaustion, I purposely relaxed the precautionary measures observed in order to be able to test the efficacy of the vaporising sulphur machine on affected leaves. The spot, as might be expected in the circumstances indicated, appeared on the plants grown under less favourable conditions on the X-shaped trellis. The plants were cleared off to-day to make room for a fresh batch of plants growing on in 32-size pots, a little lime being ferked into the ridges before setting the plants thereon. Unfortunately for the purpose of sending you fresher samples of leaves, the plants were pulled and exposed to the sun a short time before I went to obtain specimens of growth to send for editorial inspection and opinion. However, I hope those sent herewith will answer the purpose. [Corroborated. Ed.] *H. W. Ward*.

RED CURRANTS.—We are in danger of getting a little mixed over Red Currants. Various persons, in getting hold of such fine-fruited varieties as *La Versailles*, *La Fertile*, *Red Cherry*, *Fay's Prolific*, or by whatever names these large fruited may be known in commerce, hastily jump to the conclusion that they have something novel, and then give them names. Mr. Harrison Weir refers to "Comet." Why is it that neither Messrs. Veitch nor Messrs. Bunyard catalogue it? Simply because they have found it to be, as Messrs. Bunyard state in their list, the same as *Fay's Prolific*. Mr. Harrison Weir also refers to one named *Star of the North*, very possibly, by the description he gives of its growth, *La Versailles*. So recently as the 8th inst. a large-fruited variety was put before the Fruit Committee with a new name, but it was an old variety. I trust now there is ample room at Wisley a plantation of all the Red Currants in commerce will be made to clear away these objectionable synonyms. *A. D.*

STAGING CARNATIONS AND PICOTEES.—Like all florists' flowers, such as Dahlias, Tulips, *Chrysanthemums*, &c., Carnations are so arranged as to exhibit the best shape and quality of petal, form, and colour, irrespective of any artistic effect. I do not see why the florist should not have a little of his own way in the manner in which he stages his flowers. In connection with all special societies we have to listen to annual bewailings by some persons who are not florists themselves and cannot possibly have any sympathy with the ways of the florist. If every Society which is wishful to encourage the extended growth of the Carnation were to institute classes for other exhibits than the stiffly-arranged flowers they would do much to encourage the extended growth of the flower. If classes should be provided for bunches of Carnations and Picotees arranged as grown with Carnation foliage, splendid exhibits would then be forthcoming, showing well the value of the flower in its true decorative sense. At our small local show, in a neighbourhood where Carnations are highly prized, there used to be classes for individual blossoms which were scantily filled and little admired; but since bunches have been encouraged we can always reckon upon a good entry and an attractive display. *E. M.*

CAMPANULA TURBINATA "ISABEL."—Through the kindness of Mr. Prichard I have grown a plant of this *Campanula* and am delighted with it. In growth, freedom of flower, colour and natural tendency to exhibit its blossoms to the best advantage, I think "Isabel" is much the finest of dwarf-growing *Campanulas*, even better than *C. Rainier*, which is so difficult to obtain true to name, and is not so good for the rockery or for an edging to a path. *E. Molyneux*.

TRILLIUM GRANDIFLORUM.—In my garden here I grow two fairly large beds of *Trillium grandiflorum*, which bloom freely and produce ripe seeds in quantity each year. About two

years ago I instructed my gardener to sow this seed, which he did in a shallow box and placed it in a cold-frame. None of the seed germinated during the first year, but this year, being more than two years from the date of sowing, about half a dozen young plants appeared, and these have now all disappeared for the season or from decay. I may say some of the seeds have been placed in heat without the slightest effect in the way of germination. As I have a quantity of *Trillium* seed now ripening, I shall be obliged if any reader can give me a hint as to the best way to hasten the germination of this seed. *O. O. Wrigley, Wansfell, Windermere, July 24, 1905.*

SCENTS IN A MENTONE GARDEN.—As I spend much time in my little Mentone garden, and as that garden is, as all are, full of scents, I have fallen into a habit of thinking about them as I work, comparing them and noting their qualities, and the memories or ideas they evoke. Some are powerful, some delicate and elusive, some suggestive of far-away England, and some of still more far-away childhood. One of the most delicious scents, spicy rather than sweet and cloying, like the *Narcissus* and *Hyacinth*, of which one wants rather a whiff than a prolonged draught, is that of *Clematis montana*, which for some weeks is one large sheet of bloom. This and many another scent are only to be described when in the future the subject has been systematised and the descriptive terms settled, but it pervades a large portion of the garden and is only surpassed in strength by the Orange and Lemon blossoms, which fill not only the garden but the house, and that day and night for a certain season. I may recall in this connection what a surprise I once felt on opening my window after a very heavy hailstorm at a time of year when these trees were not in blossom, and yet the air seemed full of the scent. It was, I found, that of the leaves, bruised and battered by the hail. What can be more like Orange-blossom (but attenuated to a degree that requires close proximity to smell it) than the so-called *Syringa*? It is known here by its prettier name of *Citronelle*. [Two or three plants are so-called; which is the one intended?] The real *Syringa* is, of course, the *Lilac*, which has very little scent in my garden. In hot and sunny times the *Heliotrepe* breathes odours reminiscent of the childish name of *Cherry-pie*. The great white and blue *Irises* again are to me redolent of a certain period of my childhood, when I had, among other "treasures," a strange hard piece of wood, or what seemed such, which on being scraped gave out a strange smell. It came to me from some deceased elder member of my family, and I was told it was called *Orris-root*. In later times I discovered that *Orris* and *Iris* were the same thing, and when I am cutting off dead heads among my *Irises* I smell that *Orris-root* once more. I am thankful that only 6 inches or so now remain of what was once a large specimen of the evil-smelling *Eucalyptus*. Very healthy, they tell me. Yes; so are tar-soap, chloride of lime, and other disinfecting things, but never will I grow it in a garden. It "wafteth perfume o'er us which few can e'er forget." *Coronilla glauca* I grow, and overlook, so to speak, its powerful, rather rue-like smell on account of its fine masses of yellow blossoms in the spring, followed by its curious claw-like seed-vessels. The *Garlics* again, which insist on thrusting themselves in where they are not wanted like intrusive acquaintances, give me many an unpleasant moment, either when I dig them up or merely tread them down accidentally. Identical in scent with these are the really lovely *Triteleias*, which must always be planted well away from the edge of the flower-beds, since, sweet as they are to look at, a brushing skirt is enough to fill the air with a perfume of a most undesirable kind. Among the plants in my gardens which require handling to make themselves obvious to the sense of smell are the ever-sweet *Lemon Verbena* (*Aloysia*), scented *Pelargoniums*, and the very characteristically-scented *Nasturtiums*, which here grow so rampantly that they have to be kept down with a firm hand lest they should strangle all around them. They have a curious pungent odour unlike that of any other plant I know. The *Lequat*, or Japanese *Medlar*, when in bloom has a smell quite its own; so have the

SOCIETIES.

THE ROYAL HORTICULTURAL Scientific Committee.

JULY 18.—*Present*: Dr. M. T. Masters, F.R.S., in the chair; Dr. M. C. Cooke, Professor Bouger, Messrs. Masee, Gussow, Worsdell, Worsley, Saunders, and Clittenden (Hon. Secretary).

Diseased Potato-leaf.—Dr. COOKE reported on the Potato-leaf brought by Mr. SAUNDERS to the last meeting:—"The black blotch on Potato-leaves bears a superficial resemblance to that caused by *Macrosporium Solani*, but in the specimens submitted to examination no mycelium or conidia could be detected, the spots being entirely barren." The leaves were curled and blotched with yellow and black.

Contorted Teasels.—Dr. MASTERS remarked further upon these, that some plants, specimens of which he showed, had after persistent pinching at last begun to twist, a peculiarity which Prof. de Vries said was an inherited character, but which Dr. Masters, after cultivating the plants (grown from seed received from Prof. De Vries) for ten or more years, had not been able to observe before.

Diseased Mulberry-leaves.—Mr. SAUNDERS showed specimens of Mulberry-leaves from Algiers, apparently attacked by some fungus, which Dr. Cooke and Mr. Gussow undertook to examine.

Dry-rot in Floor-boards.—Mrs. DAVIES sent specimens from Deal of this too well-known trouble, caused by the fungus *Merulius lacrymans*.

White Poplar with two forms of Leaves.—Mr. HOLMES sent shoots of White Poplar showing glabrous dark green leaves on the lower part of the shoot, and white woolly-looking ones above.

Furze Dying.—Mr. HOLMES also sent twigs of Furze, which Mr. SAUNDERS will report upon.

Insects on Biota, &c.—Mr. WORSLEY remarked upon this, reported on at the last meeting by Mr. SAUNDERS, that many garden forms had been attacked and killed by the insects, while the species like *Juniperus chinensis* seemed to be little injured. He suggested that this might be due to the decrease in vigour shown by the vegetatively propagated varieties, as compared with the species usually raised from seed.

NORTH LONSDALE ROSE.

JULY 14.—During the twenty-two years of its existence the North Lonsdale Rose Society has provided the residents in the district with many floral treats. The schedule this year contained several new attractions to the grower of Roses, Sweet Peas, &c., notable amongst which was the Challenge Shield offered as a memorial to the late Mr. Jas. Hodgson. That the extension was justified is amply proved by the fact that the entry was so far in advance of last year; indeed, it was a record for the Society, and Ulverston may feel proud of the fact. The Sweet Peas also were a sight it was refreshing to behold.

MESSRS. A. DICKSON & SONS and Messrs. J. SIMPSON & SONS divided the honours in the nurserymen's section for Roses, the former carrying off amongst other prizes the "James Hodgson" Memorial Shield and the Bronze Medal for the best Rose in the show.

In the amateur classes Mr. R. L. GARNETT was the most successful, his prizes including both the Gold and Silver Challenge Cups (which he now takes for the second time in succession) and a Bronze Medal for the best Tea or Noisette.

Mr. F. J. HARRISON was also a prominent winner again, and for the third time in succession he became the possessor of the Ulverston Urban Council Challenge Cup. The "Myles Woodburne" Challenge Cup went to Mr. JOHN FRAGLE, of Rosside, Ulverston; and Miss NINA DICKSON, of Newby Bridge, took away the "Mr. Myles Kennedy" Challenge Cup.

For Sweet Peas the prizes were well distributed, both the "J. Towers Settle" Challenge Trophies going to Canforth district, the winners being Mr. R. BOLTON, Warton; and Mr. T. PROCTOR, Yealand.

WIMBLEDON AND DISTRICT HORTICULTURAL.

JULY 19.—The thirty-third annual exhibition of this flourishing suburban Society was held, in fine weather, on the above date, the tents and marquee which served to shelter the exhibits being pitched in a field adjoining the Worple Road. There were the usual groups of mixed flowering and ornamental-leaved plants, crowded or otherwise as suited the taste of the exhibitors, and no two were exactly alike. Another form of exhibit, more useful perhaps than the other, consisted of two decorated fire-places. In one of them two or three Cattleyas were placed in the grate and Sweet Pea blossoms in glasses on the mantel-shelf above, the in-

congruity being painfully obvious. Certain species of foliage plants, such as *Dracenas*, *Pandanus*, exotic Ferns, *Caladiums* and *Coleus* were shown in meritorious examples of cultivation; and the flowering plants, viz., zonal *Pelargoniums*, *Fuchsias*, *Gloxinias*, and *Roses*, left little to be desired. *Lilium lancifolium* in variety and *L. auratum* were freely made use of. Tuberous-rooted *Begonias* and herbaceous perennials formed an important part of the display; these last, being contributed mostly by the trade, were not entered for competition. *Roses* were not very abundant, whilst *Sweet Peas*, on the contrary, occupied a good deal of the available table space.

Groups of Plants to cover 50 square feet in semi-circles.—A satisfactory group was arranged by Mr. W. Thornton, gr. to T. E. CROCKER, Esq., "Draymont," Vice-President. The plants chiefly employed were *Gloxinias*, *Francoa racemosa*, *Lobelia tenuior*, *Dracenas*, and *Codiaeums*, these last of quite small sizes. This exhibitor was awarded the 1st prize, and there were in all six groups of varied degrees of effectiveness.

Groups not in the competition were set up at each end of the marquee, that by Mr. J. NASH, Belvedere Nursery, Wimbledon, consisted chiefly of *Lilium lancifolium album*, *L. l. rubrum*, *L. auratum*, *Nicotiana Sanderi*, *Verbena Miss Willmott* in considerable numbers, arranged in small compact groups, and pink and scarlet-flowered zonal *Pelargoniums*. The filling-in and ground-work plants consisted of *Caladium argyrites* and *Adiantum Capillus-Veneris*. This was the most effective group.

The corresponding group arranged by Messrs. D. S. THOMSON & SONS, nurserymen, Wimbledon, took a quadrangular form, and consisted of small pyramidal groups of various plants, such as *Golden and Silver Gymnogrammas*, *Codiaeums*, *Rex Begonias*, red-leaved *Dracenas*, the intervening spaces being filled with dwarf Ferns and flowering sprays of *Gypsophila*. The central group consisted of *Caladiums*, and the back line of the panicle *Hydrangea*, an effective feature of the whole.

For six tuberous *Begonias* (open) Mr. A. SKEGGS was 1st with finely-flowered plants, consisting of five double and one single-flowered varieties, *Salmon Queen* and *Henshaw Russell* being the prettiest ones as regards colour and form.

Single specimen plant in flower (open).—1st, Mr. G. HUTTON for *Clerodendron Balfourianum*, covered in every part with leaves and blooms.

ROSES.

Mr. Gibson, gr. to J. WORMALD, Esq., Morden Park, showed a stand of *Twenty-four Single Blooms with leaves as gathered*, not fewer than eighteen varieties, which took the 1st special prize of £2, given by Mr. and Mrs. Percy Mortimer, Ricards Lodge, Wimbledon Park. Very good were the blooms of *Maman Cochet*, *Marie Rady*, *Capt. Christy*, *Duke of Teck*, *Frau Karl Druselki*, &c.

For *twelve Roses, Distinct, Single Blooms, with leaves as gathered*.—1st, Mr. J. Wilkins, gr. to J. BRIDGEWATER, Esq., Wilton House, New Malden, with choice examples of *Horace Vernet*, *U. Brunner*, *F. Michelon*, *Marquis de Litta*, and *Mildred Grant*. 2nd, Mr. A. Snudden, gr. to J. JEEVES, Esq., Well House, whose flowers were of irregular size, and had suffered much in transit. There were smaller Rose classes, but of no great merit.

SWEET PEAS.

For the best exhibit of six varieties in bunches, Mr. J. WATSON, Junior, was 1st with good robust blooms set upon dense bunches. 2nd, Mr. C. S. JONES, whose flowers were loosely arranged, and with their own foliage and tendrils, a much better way of showing them. There were special prizes for Sweet Peas, the exhibits pleasing as regards colour and variety, if not in the manner of setting them up; and there were competitions for four bunches numbering eight.

FRUIT AND VEGETABLES.

But few exhibits of hothouse or of out-of-doors fruits were observed. The best three bunches of black Grapes, shown in the open class, came from Mr. G. HUTTON, the variety being *Black Hamburg*. The 2nd prize fell to Mr. W. Barnett, gr. to G. H. WILLIAMSON, Esq., Currie Hill, who had the same variety; and Mr. G. HUTTON was awarded 2nd prize for three bunches of some kind of Sweetwater, probably *Foster's Seedling*.

Excellent *Bellegarde Peaches* were shown by Mr. R. S. BARNETT, gr., Ricards Lodge, an exhibitor who was likewise 1st for a dish of beautiful-looking *Lord Napier Nectarines*; as also for a collection of four dishes of fruit, showing *Bellegarde Peaches*, *Lord Napier Nectarine*, *Early Transparent Plum*, and *Moore Park Apricot*. Mr. C. S. Jones, gr. to G. HAMPTON, Esq., Oxford Lodge, was 2nd in this class; and he took 1st for a dish of *Fillbasket Strawberries*, a variety that is being squeezed out of gardens by the larger-fruited, more acidulous modern varieties.

Tomatos were abundantly shown, and the 1st prize for a dish of twelve fruits was taken by Mr. J. DOWNING, gr.

Jasmine and the Japanese Honeysuckle—the latter not a bit like those grown in England. I will not dwell on *Mignonette* or *Violets*, nor can I venture on the large field of the *Roses*, for here a whole chapter would be needed. It is a remarkable thing, it seems to me, if it be true that all cultivated *Roses* come from two or three original stocks, that the scents of various kinds are so peculiar that I doubt not that a little study would enable us to classify them by scent, and to know them in the dark. When the *Roses* are over the garden scents are at an end, for here in *Mentone* "the winter flower is to the winter sweet," and with this I make my bow and resume my digging. H. A. FREEMAN, Parkside, Bromley, Kent.

ESPALIER-TRAINED APPLE-TREES.—Is there growing up a greater taste for flat-trained Apple-trees than has for a long time been evidenced? The popular bush-tree has for many years been most favoured in gardens, and has rendered great service in fruit production. Probably our Apple exhibitions now owe more to dwarf or bush trees for the fine fruit seen than to any other form of tree. But when in the fine kitchen gardens at Hackwood Park, Basingstoke, recently, I saw that during the past few years no fewer than some eighty espalier-trained trees, nearly all on the *Paradise* stock, had been planted, my mind naturally turned to the great value in gardens of this type of tree. I also wondered whether what was there seen was to be taken as indicative of a revival of a form of training and Apple production that has for a long time been too much neglected. That the espalier method of training is derived from the continent there can be no doubt, and one of the earliest recorded references to such trees in English gardens is that of Sir William Temple, who planted a large number in his gardens at Sheen, Richmond, about the close of the 17th century. It is written of these trees that after producing abundant crops for some eighty years they were destroyed, the ground having been purchased by the Crown. That statement seems to be proof conclusive that espalier-trained trees were most successful. A further instance is recorded at Twickenham, where Mr. Secretary Johnston, towards the end of the eighteenth century, planted many flat-trained trees both of Apples and Pears, and those bore heavy crops of fruit. An espalier-trained tree was mentioned and measured in 1831, which had a length of 99 feet from point to point of the branches. It was also a great bearer, and had been planted over forty years. Even now there are many fine old espalier trees about. One of the finest I have seen for a long time was a tree of the variety *Lord Derby*, at *Madresfield Court*, which several years since produced grand crops, and no doubt does so still. At Hackwood Park, Mr. Bowerman found that a few trees of *Lane's Prince Albert*, *Warner's King*, and others, as they extended, gave him splendid fruit yearly. That led to others being planted at the rate of a couple of dozen or so yearly, until now the number is, as said, about 80. The trees are planted 5 feet back from the edges of the broad grass walks, allowing ample room in front for dwarf flowers, herbs, or close-growing crops. Stakes alone are used for supports, and are probably better in some respects than are wire trellises. Certainly at Hackwood stout stakes are cheap. The general distance apart of the trees is 15 feet. Of varieties planted besides those named are *Early Victoria*, *Ecklinville*, *Peasgood's Nonsuch*, *Stirling Castle*, *Tower of Glamis*, *Newton Wonder*, *Beauty of Kent*, *Gloria Mundi*, *Hamburg Seedling*, *Bismarck*, *The Queen*, *Lord Grosvenor*, *Cox's Pomona*, and others. Kitchen Apples are in the majority, but such good dessert sorts as *Cox's Orange Pippin*, *King of the Pippins*, *Ribston Pippin*, *American Mother*, *Allington Pippin*, and *Adam's Pearmain* are included. The immobile nature of well-secured espalier trees is most favourable to large-fruited varieties, as the fruits are scarcely disturbed by wind, and can hang a long time with entire safety. A special reason, also, for favouring the rigid method of training is that the trees can be so easily netted over, not only to protect the bloom in the spring, but also the fruit in the autumn, from the depredations of the birds. A. D.

at Derwent House. 2nd, Mr. R. S. BARNETT, the varieties being respectively Best of All and Satisfaction.

In the Amateurs' division, for a collection of vegetables consisting of six kinds, distinct, Mr. J. H. SULLOCK, Arterbury Road was 1st, his Egyptian Beets, Carentan and Horn Carrots, Peas, Kidney Potatoes, Tomatos and Vegetable Marrows being nice productions.

In the classes for vegetables many of the exhibits were shown in competition for special prizes, and Mr. W. Smith, gardener to S. WILSON, Esq., Old Rectory, Wimbledon, was 1st for Messrs. Thomson & Sons' prize for ten kinds, distinct. His Potatos, Peas, French Beans, Tomatos and Turnips were excellent. 2nd, Mr. J. Dudley, gardener to J. C. PINK, Esq., with productions but little inferior to the foregoing.

Messrs. Sutton & Son's prize for six kinds, the produce of seeds supplied by the firm, was won by Mr. J. WILKINS with capital Tripoli Onions, Peas and Potatos.

There were special prizes for Peas and Tomatos, and the products shown were as a rule of more than average quality. The favourite Pea was Duke of Albany; and the Tomatos consisted of Holmes' Supreme, Sutton's Al and Princess of Wales.

NON-COMPETITIVE EXHIBITS.

Messrs. D. S. THOMSON & SONS showed hardy flowers, including the best of everything that blossoms at this date. This firm staged likewise twenty-seven single blooms of Roses, large and fully developed, besides being particularly fresh-looking. They also showed ten varieties in triplets equally good. F. M.

DURHAM, NORTHUMBERLAND, & NEWCASTLE BOTANICAL AND HORTICULTURAL.

JULY 19, 20, 21.—The summer show at Newcastle was held under exceptionally favourable conditions in respect to weather, the attendance being almost a record one for the Society. The exhibits were generally above the usual standard, and competition was keen in most of the classes. The trade exhibits were more extensive than usual.

Messrs. KENT & BRIDON, Darlington, had a large exhibit of ornamental trees and shrubs, "Malmaison" Carnations, Liliums in variety, Roses, Verbenas, and foliage plants.

Messrs. J. BACKHOUSE & SONS, York, included a miscellaneous collection of rock plants, arranged in their usual characteristic style. They had also a collection of stove and greenhouse foliage and flowering plants.

Mr. J. FORBES, Howick, had a large exhibit of herbaceous and border plants, the Delphiniums and Pentstemons being of exceptional merit. The Phloxes were very remarkable and exceptionally well grown.

Messrs. ORD BROS., North Shields, had a collection of Palms and other fine foliage plants, intermixed with specimen plants of zonal Pelargoniums.

Messrs. DOBBIE & Co., Rotheray, had a fine stand of hardy flowers, a collection of Sweet Peas, and one of Roses.

Messrs. DICKSONS, Chester, had a mixed collection of hardy flowers, the Liliums in this collection being very fine, and the Roses and Carnations making an effective display.

COMPETITIVE CLASSES.

In Class 1 for a group of miscellaneous plants arranged for effect, Mr. T. PATTISON, West Hartlepool, won the 1st prize with a neat and effectively arranged group.

The class for six specimen plants in flower is perhaps the most interesting feature of the whole show, as the exhibitors consist almost entirely of pitmen, who fill in the spare time at their disposal in the cultivation of specimen plants, the Statice, Allamandas, Stephanotis, Clerodendron, Lapagerias, and Rondeletias being remarkable examples of perfect cultivation. Messrs. R. GARDINER & GUYMER were 1st.

In the class for four specimen plants, Mr. J. DIXON, Woodside, Ryton, was 1st, the Rondeletia, Statice profusa, and Clerodendron Balfourii being perfect specimens of cultivation. Messrs. HUNTER & Co., Hexham, were 2nd.

In Class 10 for a collection of Roses arranged for effect, Mr. HUGH DICKSON, Belfast, won the 1st prize with a neatly arranged and extensive collection of good flowers. Messrs. MACK & MILNE, Darlington, were 2nd; and Messrs. HARKNESS & SONS, Bedale, 3rd.

For thirty-six Roses, distinct, Messrs. G. and W. H. BURCH, Peterborough, were 1st.

In a class for forty-eight Roses, distinct varieties, Messrs. J. SIMPSON & SONS, Dundee, were 1st.

For twelve Rose blooms of one variety, Messrs. SIMPSON & SONS were 1st with fine examples of Frau Karl Druschki; and Mr. J. GARDENER, Whickham, 2nd, with the same variety.

The best exhibit of twelve blooms of a Tea Rose was also from Messrs. SIMPSON, with the variety White Maman Cochet.

FRUIT.

In a class for a collection of eight dishes of fruit, Mr. J. C. MCPHERSON, Londesborough Park, Market

Weighton, won the 1st prize, the Grapes, Apples, and Peaches in this collection being of exceptional merit. Mr. E. COMBEY, Lambton Castle, was 2nd; and Mr. W. NICHOLLS, Carlton Towers, 3rd.

For a collection of four dishes of fruit, Mr. MCPHERSON was again 1st; and Mr. COMBEY, 2nd.

For four bunches of Grapes Mr. W. Mark, gr. to Miss MARCHAMP, Farnley Hill, Corbridge, was 1st; and Mr. J. C. MCPHERSON, 2nd.

The best exhibit of two bunches of white Grapes was from Mr. J. C. MCPHERSON.

Mr. D. WILLIAMS had the best dish of Nectarines, and Mr. NICHOLLS the best dish of Peaches.

Mr. J. C. MCPHERSON was 1st for twelve Tomatos.

For a collection of vegetables in eight varieties, Mr. E. KEATH was 1st; Mr. F. BRIGGS, 2nd. Mr. J. C. MCPHERSON won 1st prizes for collections of eight and six dishes respectively.

CUT FLOWERS.

The best bridal bouquet was shown by Mr. T. BATTENSBY, and the best hand bouquet (Orchids excluded) by the same exhibitor. Mr. EDMONSON won the 1st prize for a basket of Roses. For a dinner-table arranged for effect Mr. BATTENSBY won the 1st prize, and the best basket of cut flowers was arranged by the same exhibitor. The best collection of Sweet Peas was from Mr. KEATH.

In the class for twenty-four bunches of hardy flowers Messrs. HARKNESS & SONS were most successful, and for eighteen bunches Messrs. GIBSON & Co., Bedale, were 1st.

The whole of the Amateur and other restricted classes were well filled, and a keen competition in most classes was the result.

Sweet Peas were far more extensively shown than in previous years. H. J. C.

BRITISH GARDENERS' ASSOCIATION.

JULY 21.—The newly-elected Executive Council held its first meeting on the above date, at the Hotel Windsor, Victoria Street. The Secretary, Mr. Watson, reported the progress made since June 1. Twenty-seven new members had joined, bringing the total number up to 650, and donations amounting to £11 17s. had been received, including £10 from Mr. A. K. Bulley, who wrote:—

Dear Mr. Watson—I am afraid I am too far from the centre of action to enter effectually into your movement. But the substitution of organisation amongst gardeners for the present vexatious and chaotic conditions, seems to me wholly good. Its main object must of course be the benefit of gardeners by the thousand-and-one channels which association is always able to command. But it will also be a great advantage to all employers who believe in good work and good pay, for it is certain that it will be the most enlightened and intelligent section of the workers who will be the most prompt to join an Association for the common good.

I wish you well, and enclose £10 towards your initial expenses. Try as soon as you can to get the Association free from any charity basis, even if it means considerable pinching and work done without pay; it is better to do what you can on the saved pennies of the gardeners.—Yours faithfully, ARTHUR K. BULLEY.

Attention was called to the remarks of Sir W. T. Thistleton-Dyer, as well as to those of the Duke of Westminster at the annual dinner of the Gardeners' Royal Benevolent Institution, on June 16. His Grace then said: "But the life of the gardener was not literally a bed of Roses, nor were his gains great. He was a skilled workman who gave an infinite amount of pleasure to the community at large by his labour and ingenuity, and yet his wages compared very unfavourably with those of skilled workmen in other branches of industry. Few gardeners could afford to lay by from their wages a sufficient sum to enable them to meet the rainy day or the inevitable prospect of old age. He therefore commended the charity to their notice, confident that when its objects were more generally known further generous contributions would be forthcoming."

The Council decided to make arrangements for a Conference of members and others interested, to take place in October, during the great autumn fruit show of the Royal Horticultural Society. To this Conference branches of the British Gardeners' Association will be invited to send delegates. A proposal to engage the services of a paid secretary to devote his whole time to the work of the Association was considered, but the Council decided that in the present condition of the Association it would be unwise to incur the expense of a paid secretary and a central office. The Council hopes before long to make arrangements for monthly meetings to take place in or near the Royal Horticultural Society's Hall in Vincent Square concurrently with the meetings of the Royal Horticultural Society.

On the motion of Mr. Winter, seconded by Mr. Watson, Mr. J. Weathers was unanimously elected

hon. secretary of the Association. All communications affecting the British Gardeners' Association should therefore in future be addressed to Mr. J. Weathers, Talbot Villa, Isleworth, Middlesex.

The members of the Executive Council are:— T. H. Candler, The Gardens, Warley Place, Great Warley; G. H. Clack, Putney Park, Putney; W. E. Close, Superintendent of Parks, Fulham; C. H. Curtis, 2, Adelaide Road, Brentford; W. Dallimore, Royal Gardens, Kew; G. Gordon, Priory Road, Kew; J. Lawson, Horticultural College, Swanley; R. Hooper Pearson, 40, Brookelbank Road, Wandsworth; W. Taylor, The Gardens, Tewkesbury Lodge, Forest Hill; W. Watson, Royal Gardens, Kew (Chairman); J. Weathers, Talbot Villa, Isleworth (Hon. Secretary); T. Winter, Superintendent of Parks, Marylebone.

Grapes, Alicante, per lb. ...	0	8-1			

REMARKS.—The Strawberry season may be considered over. There are a few in punnets and pecks, but these are mostly bought by the smasher for the making of jam. Cherries are still arriving in moderate quantities, and the best samples make good prices. Peaches and Nectarines are plentiful, and very good prices are obtained for them, considering the large quantities arriving daily. Rock Melons are arriving from France in very good condition. Prices for these are a little lower, owing chiefly to the hot weather, which turns them soft very quickly. English Grapes are coming on to the market. There is not much trade for Muscats yet, and only good ripe fruit is saleable. A few good bunches of Madresfield Court were to be seen on this market last week, but there was little demand. Gros Colmar, Black Alicante, and Black Hamburgs sell best. Trade generally is very good.

DOVET GARDEN FLOWER MARKET.

The London trade for pot plants is now practically over for the season. A few best flowering plants may still be wanted, and there is a little trade for country orders. We are still getting very good Pelargoniums, but the "show" varieties are not quite so plentiful. Zonal varieties are very good, especially F. V. Raspail and King of Denmark. The Ivy-leaved varieties vary much, but Galilee is the best. Verbenas are overplentiful; a variety called The King, from Mr. Sweet, is very fine. Rose Dorothy Perkins is very good from the same grower. Fuchsias vary much in quality; some good plants are seen, but others are of rough appearance. Campanulas are very good; C. isophylla alba is the general favourite. There are several varieties with blue flowers, but the true isophylla appears to be even better than C. i. Mayi, though the latter may be a little deeper in colour. C. pyramidalis, white and blue varieties, are very pretty. Heliotrope is now very good and over plentiful. A few well-flowered plants of the new Gypsophila paniculata flor-pleno are seen. Of Marguerites, white and yellow varieties are still seen, but they are not quite so plentiful. Rhodanthe is very good. Hydrangeas are now nearly past, and what are left are not of the first quality.

Liliums are plentiful, L. Harrisii in good dwarf plants make only about 12s. per dozen. L. lancifolium, both white and rose-coloured varieties, are good. To Ferns there are now some fine plants of Nephrolepis Miersonii, but I find this does not sell so well as might be anticipated. N. Fosteri is also good, and N. Westonii is a good market Fern. These come from Messrs. Cragg, Harrison & Cragg, who were the raisers of the last-named variety. Small Ferns in variety are very plentiful. From Messrs. Denson Bros. are some very fine plants in large 6's. Euonymus, Golden Privet and other hardy shrubs are now filling up some of the stands. Palm growers still send plants, but the trade for them is very quiet.

CUT FLOWERS.

We are already getting some very fine Chrysanthemums, the yellow and the white varieties of Madame Desgranges, from Mr. P. Ladds, are remarkably good. It may be too early to suit some, but they sell well at 3s. per dozen blooms, and some may make more. This useful early Chrysanthemum has certainly been improved by careful selection of stock since it was first distributed. A few years ago, when growing it in Sussex, I found there was considerable variation in a large batch growing in the open ground. All growers will do well to be careful in selecting for stock purposes. Liliums are plentiful; the best L. auratum make 3s. per bunch, but L. lancifolium and longiflorum are very uncertain in price. I also find that Lily of the Valley varies very much. There are large supplies of Roses coming in; the best sell well, but many have to be sold very cheaply. Carnations are now low in price; best American varieties on long stems may be had at from 2s. to 2s. 6d. per dozen. Stephanotis was scarce this morning, but it has previously been very cheap. Tuberose, Gardenias, and Eucharis may be had at moderate prices. Sweet Peas are still fairly good, but prices are low. Hardy flowers are overplentiful. Several growers are sending the Shasta Daisies in large quantities. Gypsophila is seen in large "heaps." Calliopsis, Gladioli, especially The Bride and brechenleyensis, are overplentiful. There are large supplies of all kinds of cut foliage. The Oak with bronzy-red leaves is now very pretty. Hardy grasses in variety, and fronds of hardy Ferns are very plentiful. A. H., Wednesday, July 26.

duration ranged from 58 in the Channel Islands, 57 in England, S., and 55 in England, E., to 19 in Scotland, N., and to only 13 and 12 respectively in Ireland, N. and S."

THE WEATHER IN WEST HERTS.

Again very Warm, Dry and Sunny.—Another warm week, and the sixth in succession. On the warmest day of the past week the temperature in the thermometer-screen rose to 81°, and on the warmest night the exposed thermometer did not fall lower than 58°. The ground is now very warm, the readings at both 1 and 2 feet deep being about 3° warmer than is reasonable. There has been no rain worth mentioning since the 9th inst., or for over a fortnight. Consequently the soil is becoming dry, but every morning a few drops still trickle through the bare soil percolation gauge. As in the two previous weeks there was again a splendid record of sunshine. Taking the week as a whole the mean daily duration was nearly 8 hours a day, which is 1½ hour a day in excess of the July average. Calms, and light airs again prevailed, the direction of these light airs being exclusively from some westerly point. The mean amount of moisture in the air at 3 P.M. was 1 per cent. less than is usual at this season. E. M., Berkhamstead, July 26, 1905.

[For actual temperature and condition of barometer at time of going to Press, see p. 90.]

TRADE NOTICES.

BEDFORDSHIRE SEED COMPANY, LIMITED.—The above-named company has been registered with a capital of £2,000 in £1 shares. Object, to carry on the business of seed growers and merchants, nurserymen, market gardeners, forage contractors, produce dealers, salesmen, manure merchants, box manufacturers, land agents, &c. No initial public issue. The first directors (to number not fewer than two nor more than five) are to be appointed by the signatories. Qualification (except first directors) 100 shares.

REIGATE MUSHROOM COMPANY, LIMITED.—This company has been registered with a capital of £5,000 in £1 shares. Object, as indicated by the title. No initial public issue. The first directors are F. J. Bolton (permanent governing director), and others to be appointed by the signatories. Remuneration of F. J. Bolton £150 for the first year, rising by annual increments. Registered office, Willow House, Godstone, Surrey.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending July 22, 1905.

1905.	TEMPERATURE OF THE AIR.				TEMPERATURE OF THE SOIL AT 9 A.M.			RAINFALL.	SUNSHINE.	
	At 9 A.M.		DAY.	NIGHT.	At 1-foot deep.	At 2-foot deep.	At 4-foot deep.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending July 22, is furnished from the Meteorological Office:—

"The weather was generally fine and dry over England, but slight falls of rain were rather frequent in Scotland and Ireland. Thunder was heard at a few Scotch stations during the earlier half of the week.

"The temperature continued above the mean, the excess ranging from 1° in Scotland, N., to 4° in Ireland, S. The highest of the maxima occurred, with few exceptions, either on the 21st or 22d. In England, S., the thermometer rose to 83°, and in several other English districts to 82°; but in Ireland, N., and Scotland, W., the respective values were 72° and 75°. The lowest of the minima were recorded mostly on the 19th, and varied from 35° in Scotland, N., and 39° in Scotland, E., and England, S.W., to 51° in Ireland, S., and to 54° in the Channel Islands.

"The rainfall was slightly in excess in Scotland, N. and W., and Ireland, N., but was again less than the mean in all other districts. In some parts of central England the week was almost rainless.

"The bright sunshine exceeded the mean over England, the Channel Islands, and Scotland, E., but was deficient elsewhere. The percentage of the possible

CATALOGUES RECEIVED.

THE STREBEL SECTIONAL BOILERS.—These boilers are made in many varieties, and are constructed of sections of the same pattern without changing the relations between heating-surface, grate, fire-box, and flues. The Strebel apparatus is used in the Hamburg Botanic Gardens, at Versailles, Zurich, and many other widely-known places. The London agent is R. O. Meyer, Ltd., Norfolk House, Norfolk Street, Strand.

GARDENING APPOINTMENTS.

MR. JOHN TOY, several years Gardener to Sir E. BLACKETT, Bart., Matfen Hall, Corbridge-on-Tyne, as Gardener to J. W. SIBNER, Esq., Newbiggen House, Kenton, Newcastle-on-Tyne.
MR. JAMES JEFFREY, from the Royal Nurseries, Craigmillar, Edinburgh, as Gardener to the Right Honble. Earl of ANCASTER, Drummond Castle, Perthshire.
MR. T. CATTLEY has succeeded Mr. J. PEACOCK in the charge of Sir EDMUND LECHMERE'S Gardens, Whitwell Hall, York.
MR. E. CROOK, Gardener at Lostock Dene, Bolton, for nine years, as Gardener to E. ASPINALL, Esq., Overdale, Bolton.
MR. R. WATSON, late of Letton, as Gardener to R. J. COLMAN, Esq., Crown Point, Norwich, entering his duties August 1.
MR. J. KILDING, who has been Foreman for five years under Mr. LEACH at Albury Park, as Gardener to Lady MARY HOLLAND, Kneesworth Hall, Royston, Herts.

ANSWERS TO CORRESPONDENTS.

ACALYPHA LEAVES: *W. J.* The warts on the under surface of the leaves are most probably due to the irritation caused by the bites of an extremely minute insect—a mite. Pull off and burn the affected leaves, and apply Tobacco-water freely to the lower surface of the remaining leaves as far as you can do so.

ALSTROEMERIAS: *Barnham Nurseries.* The Alstroemerias seen in the market vary a little in colour, some are much deeper in shade than the ordinary *A. aurantiaca*; they are bunched in about eight to twelve stems to each bunch. There is not a big trade for them, all hardy flowers are abundant at the present time, and trade for them is very uncertain.

ANTS IN ORCHID-HOUSE: *M. L.* We have frequently answered a similar question. Kindly refer to our issue for July 1, p. 20, col. 1.

BEET: *L. F. F.* The fault is not with the soil or manures, but with the variety. You have probably what is known as a green-leaved Beet, but the roots may be as blood-red as any other. In the variety known as Cheltenham Green Top, for instance, the contrast in colour between the root and the foliage is extreme. If you want a Beet for ornamental purposes, Victoria is one of the best.

BEGONIAS: *Derbyshire.* The soil appears unsuitable.

BOOKS: *Rosarian.* There are plenty of modern books on Roses, but none give many plans of the nature you require. You had better obtain *The Rose Garden*, by the late William Paul, from our Publishing Department, price 11s. 2d., with plain woodcuts; or 21s. 8d. with coloured plates, post-free. This work is the best of those published on the Rose, and contains a number of plans for the formation of Rose gardens.

COUNTY COUNCIL PARKS: *A New Reader.* Apply to Colonel Sexby, General Superintendent of the London County Council Parks, at his office, 11, Regent Street, London, W. We cannot express an opinion upon the length of time you would have to wait for an appointment, but provided your application is entertained, any delay would be occasioned by the lack of a suitable vacancy.

DUTIES OF AN ENGLISH FORESTER: *Perplexed.* The nominal duties of an English forester are such as those mentioned by you, and there is no reason why your experience in South Africa should not qualify you for a post in England, provided you can acquire the necessary experience in the practical details which are more or less peculiar to this country, such as fencing, sale of timber and other produce, and other matters which have only local application to forestry practice. But you will probably find that the class of appointment you are desirous of obtaining is limited to a few large estates in England and Scotland, and when vacancies occur they are usually filled by men who have spent the best part of their lives on similar estates in a subordinate position, or as assistant-foresters or foremen. Even on such estates it is often the custom to combine the duties of a forester with those of other departments, and the forester is often a sort of handy-man who is expected to do any work which comes in his way, and to occupy a position which is occasionally trying to an educated man. Whether you would be willing to occupy such a position in return for a salary varying from £70 to £150 per annum, you must decide for yourself, but unless you have exceptionally good fortune or can command a good deal of influence amongst estate-owners and their agents, your only chance of obtaining such a post would be by working under an experienced forester for two or three years, and thus joining the class from which forestry appointments are filled. Probably the Colonies offer the best field for a man in your position and with your experience, and appointments in them are occasionally made through the Colonial Office, to which you might apply.

EMPLOYMENT AT KEW: *H. Davies.* See reply published in this column in our last issue. Write to the Curator of the Royal Gardens for a form of application.

FAILING PLANTS: *H. Boyd, Blackburn.* Too much water is the principal cause of the trouble. The plants are quite free from any injury caused by insects or fungi.

FERNS: *A. H. P.* The fronds appear to have been taken from an old, worn-out stunted plant. It is better to bring on young stock than to keep old plants. Steep the fronds in tobacco-water mixed with a little soft-soap.

FIGS: *W. J.* The fruits appear to have no disease, and the decay is therefore caused by lack of sufficient ventilation at a time when the atmosphere is very moist. Do not syringe the fruits at this stage, and if any of the leaves are disfigured, as if by disease, you may send them for our inspection.

FUNGUS WITH GRASS: *P. B. & Sons.* The fungus sent is an imperfect state of Polyporus (*Fomes*) *lucidus*.

FUCHSIA: *De St.* It is impossible to guess what species or variety of Fuchsia you may have cultivated about the year 1835, because there were already at that date, and even ten years earlier, at least half a dozen species in cultivation, to say nothing of varieties raised in gardens. Probably it may have been the one which was then known as *coccinea*.

INSECT: *A. G.* The insect (?) arrived in a putrid condition.

"MALMAISON" CARNATIONS: *Juvenis.* The name is an abbreviation of *Souvenir de la Malmaison*, which in English would mean "In memory of the Malmaison." Malmaison was the name of a very celebrated palace at Versailles, near Paris, where the Empress Josephine lived, and the Carnation may have been named in memory of that palace, but of this we are not certain. Regarding the history of this type of Carnation, Mr. Brotherton states in *The Book of the Carnation* that the original plant was raised from seed by M. Laine, a Frenchman, in 1857. Mr. David Thomson cultivated the plant at Archerfield in 1864, having received the stock from Mr. William Young, of Edinburgh. The variety Lady Middleton is stated to have appeared at Luffness, in East Lothian, in the year 1870, and the pink Malmaison a few years later (1875) in a garden near Musselburgh. Since that date, Mr. Martin R. Smith and other raisers in England and on the Continent have succeeded in obtaining numerous varieties of this type by cross-fertilisation.

MELONS: *W. F. O.* The fruit has cracked owing to the plant having been afforded too much water at the roots. In order to get good Melons of high flavour, it is necessary to decrease gradually the amount of water afforded to the roots, and also the degree of moisture in the atmosphere as soon as the fruits have attained to their full size. Some growers may push this practice to the extreme, and by the time the fruits are ripe the plants die from drought. We do not advise this, but at the same time slightly drier conditions are necessary in order to develop flavour and to prevent the fruits from cracking.—*H. C. D.* There is nothing in the fruits themselves to explain why they have fallen from the plant, and you have furnished no particulars.

MELON SEEDS: *G. G.* We have frequently seen the seeds of Melons and similar fruits germinating while still within the fruit. The conditions are so favourable for such germination that we wonder it does not occur more frequently.

ORANGE RUST: *H. A. E.* Burn the leaves and spray the plants with the Bordeaux-mixture.

ORNAMENTAL FOLIAGE PLANTS: *W. H. S.* Unless the schedule states that Ferns are excluded, we should expect them to be admitted in a class for ornamental foliage plants. We may point out, however, that at many exhibitions there are separate classes for Ferns, and in such cases the schedule generally excludes Ferns from the class for six ornamental foliage plants.

NAMES OF PLANTS: *J. F.* *Staphylea pinnata*, Bladder Nut.—*T. B. B.* *Quercus coccinea*, *Pyrus terminalis*.—*H. K. G.* 1, *Taxodium distichum*; 2, *Hypericum androsaemum*; 3, *Cupressus Lawsonia* variety; 4, *Lysimachia nummularia*; 5, *Thuja orientalis*; 6, *Juniperus chinensis*. *G. F. S.* *Brounus erectus*.—*No sender's name, but apparently from Easing-stoke.* 14, *Spiraea hypericifolia*; 15, *Leycesteria formosa*; 16, *Dentzia crenata*; 17, *Spiraea callosa*.—*W. B. G.* *Portulaca Gilliesii*.—*B.* *Catalpa bignonioides*.—*G. P.* *Calycanthus occidentalis*, The hybrid *Dianthus* is interesting.—*P. L. H.* *Cypripedium Godefroyi*.—*F. L. 1.* *Epipactis latifolia*; 2, *Pyrus salicifolia*; 3, *Pyrus* not recognised; 4, *Crataegus tanacetifolia*; 5, *Quercus coccinea*; 6, *Fagus sylvatica* var. *heterophylla*—the cut-leaved Beech.—*F. E.* *Anerley.* *Medicago scutellata*.—*G. F. & Co.* *Astrantia minor*.—*Ted.* *Fuchsia fulgens*; any of the larger nurserymen.—*F. T.* 1, *Adiantum pedatum*; 2, *Nipholobolus lingua*; 3, *Lastrea filix-mas*; 4, *L. decomposita*; 5, *L. serra*; 6, *Pteris scaberula*.—*A. B.*, *Hereford.* 1, *Spiraea callosa*; 2, *S. Douglasi*; 3, *Leycesteria formosa*; 4, *Rhus Cotinus*; 5, *Lysimachia clethroides*; 6, *Aconitum Lycoctonum*.—*W. U.* *Spiraea Douglasi*; for name of beetle see next week's issue.

PEACHES: *E. L.* The cause cannot be determined from the over-ripe fruits sent. It is certainly not due to any fungus.

PEACH LEAVES: *L. F.* The brown patches and subsequent holes in the leaves are not due to the soil, but to what is termed the "shot hole fungus" (*Cercospora circumscissa*). The best preventive means consist in spraying the trees with an ammoniacal solution of copper carbonate just when the leaves are expanding early in the season, and repeating the operation at intervals. You should not use the Bordeaux-mixture upon Peaches, as it causes injury to the leaves and the shoots, even when the mixture is diluted.

PRESERVING PEAS: *T. S.* To bottle green Peas, shell the Peas, put them into dry wide-mouthed bottles, and shake them together so that they may lie in as little space as possible; cork the bottles closely, and seal the corks. Bury the bottles in the driest part of the garden, and take them up as they are wanted. They ought to keep good for some months. Or try this recipe. Choose Peas which are large and fully grown, though not old. Put them into perfectly dry, wide-mouthed bottles, shake them down, cork securely, and cover the corks with bladder. Tie a wisp of hay round the lower part of the bottles to prevent their knocking against each other in the pan, put them side by side in a large saucepan, and pour into it as much cold water as will reach to their necks. Put the saucepan on the fire, and let the bottles remain standing in the water for two hours after it has reached the boiling point, then take them off, but do not remove the bottles until the water is cold. Seal the corks, and store in a cool, dry place.

ROSES: *Hoyleake.* Watch in the evening to see if there is not some insect at work.

TOMATOS: *H. R. H.* and *H. R.* The black spot is due to a fungus, and has been repeatedly figured in these pages. Burn the affected plants, and spray the healthy ones with weak Bordeaux-mixture or liver-of-sulphur, $\frac{1}{2}$ oz. to a gallon of water. Procure a copy of the *Calendar of Garden Operations* from our Publishing Department, price 7½d. post free. You will find full particulars and illustration in that little book.

MARKET GARDENING AT EVESHAM.

FEW centres of horticultural industry present so many features of interest as that comprised in the general term, "the Vale of Evesham." Picturesque, varied and beautiful scenery, highly developed intensive cultivation, a busy colony of workers, with fertile soil yielding to tenants and owners an ample return, constitute a pleasing and instructive study.

The river Avon takes a long curving course through Evesham, and winds some fifteen miles to Pershore, with high banks and hills on either side, a large proportion of which is occupied with fruit-plantations. Thousands of acres upon these slopes with varied aspects have the lines of trees running almost from the water-level to 100 feet or more above it. Plums largely predominate, and at flowering time these banks of snowy blossom afford a most beautiful spectacle, which attracts numbers of visitors from the large manufacturing towns. This spring the display was most profuse; in fact trees could not bear a greater number of flowers, but now some could not have a smaller number of fruits—rather a striking descent from the poetic ideal to prosaic reality. But such risks and vicissitudes are part of the horticulturist's lot, and the Evesham growers have learned by experience to make provision against possible losses. Few rely upon fruit alone, and every available space under the trees to within a few inches of the stems is occupied with a crop of some kind during the greater part of the year.

Throughout the winter and early spring cabbages and Lettuces fill up a large pro-

portion of the space. Radishes and spring Onions form important crops, which come off the land before the trees are in leaf, followed by Asparagus, Peas, and Broad, dwarf, or Runner Beans, with Vegetable Marrows. The Asparagus is, of course, a permanent crop, but the beds are commonly taken between the lines of trees, and often very close to them. Where the slope of the land is convenient and the aspect is good, particularly near Greenhill, which rises above the Great Western station on the Worcester and Alcester roads, the trees are planted closely in lines 20 or 30 yards apart, the spaces between, having a southerly slope, are devoted to vegetable or flower crops, or occasionally to Strawberries. A continual close intercropping is followed, and it is astonishing what large quantities of produce are obtained from comparatively small areas of land. The soil is naturally fertile, and well repays cultivation. A large part of the fruit-land cropped in market-garden methods is forked or dug entirely by hand, and it must have had this treatment for many years. Indeed, the Abbey gardens, that are now let as allotments in small plots (the rent of which is from £40 to £50 per acre), have been under cultivation for hundreds of years, from the day when Evesham Abbey was one of the most flourishing establishments of its kind.

Manure of organic origin is scarce and costly in the district, but artificials of various kinds are extensively used, together with fish and other manures. The application however which is most valued in the district for Asparagus especially, but also for other crops, is soot, of which heavy dressings are employed, and the supply of this substance is quite an important trade in the neighbourhood. Though of low manurial value as regards its percentage of ammonia, there is no question that it produces some marked effects, and if one might feel a prejudice against it theoretically, experience proves that it is by no means to be despised, as the physical action on the heavy land is conspicuous.

One point as regards the Plum-trees cannot fail to strike the observer, and that is the close planting adopted; numbers can be seen of considerable size not more than 10 feet apart, and many are within 6 feet of each other in the lines. It seems regrettable, and likely to shorten the profitable period of the tree's life very materially, while thinning is scarcely practicable when the trees have reached full size. Careful examination of many plantations shows, however, that this crowded planting has at least one important advantage from the fruit-growers' point of view, namely, the reduction of growth and the consequent promotion of early fertility. In all the stronger soils around Evesham young Plum-trees make an astonishing growth. I have seen shoots over 6 feet long of the current season's growth, and some that were pruned this year to about 18 inches length have on each shoot four or five growths averaging nearly 4 feet in length already. It is obvious that while a tree is quickly formed in this way, it is rather opposed to fruit-bearing, and the Evesham growers, like others, have found that close planting corrects the tendency to excessive growth, and no doubt the constant cultivation around the trees has an effect in the same

direction. Certainly, in the crowded plantations every branch and shoot is in bearing condition, and very little superfluous growth is produced. Still, some have gone to the extreme, and undue crowding leads to other troubles; for instance, an invasion of insect pests is more disastrous and difficult to deal with in these dense plantations. It is scarcely probable also that the trees are so lasting, though when a cultivator is concerned to obtain immediate returns for a living, it is not likely he will overlook that for a possible advantage ten years hence.

Taking it altogether, the cultivation in the Evesham district compares favourably with that in any market gardening centre known to me, and in my opinion the general system is the right one, namely, a combination of vegetable-growing with fruit. In a good season the fruit crops come as a substantial addition to the resources, but if by the closest intercropping and the best cultivation, a grower can manage to pay expenses and keep himself on his intermediate produce, he is in a sound financial position, in a measure independent of bad seasons. At least he has not the reason to fear a total collapse, as may occur when he has out-door fruit alone to rely upon.

For a small population the proportion of growers who have raised themselves from humble beginnings to easy circumstances is considerable. But such results have not been secured without hard and continuous work, not only for the man but often for the wife, together with the sons and daughters as they reach an age to be useful. It has not been a case of sitting down and waiting for the Plums to fall into their mouths. During the busy season Evesham workers are about between 3 and 4 A.M., and many work until late in the evening. This is solid toil which few town-dwellers could endure for a week, and whatever results have been secured have been well earned. Perhaps the chief mistake committed is that of taking too much land before the workers are in a position to employ sufficient labour to keep it in the right condition. Many plots range from 3 to 10 acres in extent, and occasionally one man may hold several plots widely scattered around the town, two or three miles apart. This necessitates much loss of time in travelling backwards and forwards, and some of the plots which may not be in a productive state are partially neglected while the crops are being obtained elsewhere. On the heavy soils the land quickly becomes foul, and when once in arrears with cleaning work it is very difficult to overtake it again; besides much future mischief is provided by the innumerable seeds produced.

Allotments that are not occupied with fruit or Asparagus are eagerly sought because the grower knows that by stocking the land with either crop he is ensuring a safe investment for his labour and expenditure in addition to the produce he actually raises. The "Evesham custom" has been strongly recommended by the Board of Agriculture Departmental Committee for adoption in some modified form, as the law of the land provides a simple means of dealing with the difficult question of compensation. The majority of the small holders are yearly tenants, and might therefore have their rents raised continually unless there is some agreement on the

matter. But for all crops on the land the tenant when leaving his holding obtains compensation from the incoming tenant, unless the landowner wishes to take possession himself, when he would have to pay the requisite compensation by valuation. The landlord also has the right of refusing a proposed new tenant; but it is only in extreme cases that this is exercised. The arrangement seems to work very well, and plots sometimes change hands at valuations ranging from £20 to £100 per acre, the latter being only secured for the best fruit-land, well cropped and cultivated. *R. Lewis Castle.*

whose garden it flowered, and to whom I owe the opportunity of describing it. This new species is allied to *A. striata*, Haworth, and is best placed in the section *Saponariae*, though through its sub-stipitate perianth it shows possibly some relations with the section *Grandes* of Mr. A. Berger. *S. Schönland, Albany Museum, Grahamstown, June 24, 1905.*

STANHOPEA WOLTERIANA, *Kranzl., n. hybr., artef., S. MARTIANA ♂ × S. TIGRINA ♀* (see fig. 35).

We cannot better describe this new hybrid than by stating that it is like *Stanhopea tigrina* with the colours of *S. oculata* var. *crocea*, or of *S. devoniensis*. The dorsal sepal is ovate-oblong, the

more or less regular lines; the petals and the base of the lip have larger and rather deeper coloured blotches; the horns of the blade (the so-called epichilium) of the lip are spotted in the same manner; the back of the column is greenish. The fully-expanded flowers when measured across are between 5 and 6 inches broad; the lip is 2 inches long. The horns at their greatest divergence are 2 inches apart, the deeply three-pointed blade or epichil is $1\frac{1}{2}$ inch long and broad. The perfume of the fresh flower is very strong, but it seems to be not so overpowering as that of *S. tigrina* when in all the full splendour of its freshly-opened flowers.

The plant was raised by Mr. Paul Wolter, of Magdeburg. The sowing was made just four years ago, and the seedlings are now producing their first flowers. The first spike I received had three flowers, the lateral ones diverging at right angles, the axil and the ovaries densely covered by sheaths and bracts. Four years seems to be the usual age at which *Stanhopea* seedlings

FIG. 34.—ALOE CHABAUDII: FLOWERS RED.

NEW OR NOTEWORTHY PLANTS.

ALOE CHABAUDII, SCHÖNLAND, N. SP.*

THIS apparently very distinct new species was collected by Mr. J. M. Brown some five or six years ago when on a hunting trip to the Zambesi. Its exact locality is unknown. It was given by him to Mr. John A. Chabaud, of Port Elizabeth, a well-known enthusiastic amateur gardener, in

* *Aloe Chabaudii*, *Schönland, n. sp.*—Acaulescent. Leaves eighteen to twenty-four, forming an irregular rosette; up to 19 inches long and 6 inches broad near the base, about $\frac{3}{4}$ inch thick, ovate-lanceolate, unspotted, somewhat glaucous; upper surface indistinctly striate, nearly flat, except near the apex, where it is channelled; lower surface slightly convex; margin with a narrow lacy border; prickles $\frac{1}{2}$ inch long or even smaller, at first flesh-coloured, brown in older leaves, straight or (especially in the upper portion of the leaf) curved forward, about $\frac{1}{2}$ inch apart, interspaces straight. Inflorescence a loose panicle with squarrose ascending branches 24 to 30 inches in height, about 18 inches in diameter; racemes lax, floriferous portion 6 to

lateral ones are obliquely ovate and somewhat falcate; the petals much narrower, linear, waved at the edges and curled backwards; the lip has exactly the form of that of *S. tigrina*, but is perhaps somewhat smaller; the column has the characteristic broad wings of *S. tigrina* in the middle of its length; the foot is wingless, but there are two small wings at the top that are wanting in *S. tigrina*. The ground-colour is dull straw-yellow or pale-orange; the sepals have obscure wine-red blotches and spots in

8 inches long; bracts deltoid acuminate, membranous, lowest about $\frac{1}{2}$ inch long, upper gradually smaller; pedicels spreading, lowest $\frac{1}{4}$ inch long, upper only slightly smaller; perianth $1\frac{1}{4}$ inch long, slightly curved, distinctly obconical at the base, swollen round the ovary, with three decided oblong indentations above it (in a line with the inner segments); outer segments pale brick-red with nearly white wings near the apex, inner with red median line and pale wings, which are yellowish at the apex; tube of corolla nearly two-thirds its length; filaments yellow, slightly exceeding the perianth in length, anthers pale terra-cotta; ovary broadly oblong, green; style yellow, not exerted; stigma very small, capitate.

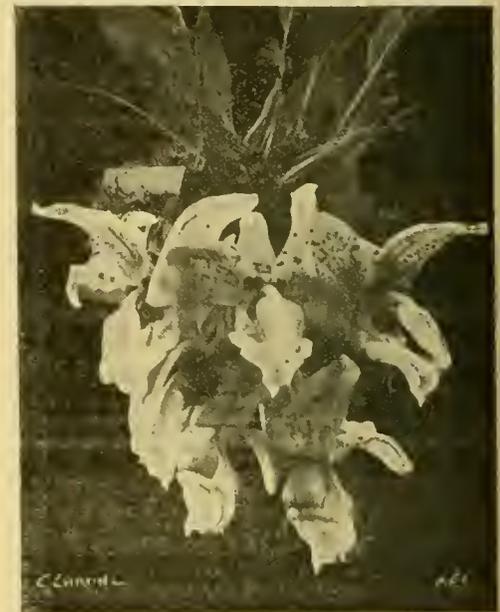

FIG. 35.—STANHOPEA WOLTERIANA X.

bloom. The first hybrid of this genus, *S. Spindleriana*, *Kranzlin* (*S. tigrina* × *oculata*), also flowered after that time.

Stanhopeas generally speaking are not in favour in England, though it is hard to understand why they should not have their place in amateur collections. To cultivate they are the easiest of all Orchids, as they require neither special treatment nor a great amount of heat. They keep their bright, gay-looking foliage all the year round, and a dozen baskets of these plants hanging in a greenhouse in summer-time, or on the branches of trees in a garden, producing their drooping spikes of fantastic flowers, have a pleasant effect, and give us some idea of the treasures of the (western) Garden of the Sun. Sixty years ago the English gardening world must have had other tastes, the volumes of the *Botanical Magazine* and *Botanical Register* being full of plates representing *Stanhopeas* and their varieties, and from the remarks made in the text we learn that those plants were then highly appreciated. Many of the garden and botanical worthies of this period are immortalised by a *Stanhopea*.

Certainly *Stanhopeas* "do not pay," nor do the Ivory Orchids (the Eborilungues of botanists), and professional gardeners will certainly decline to grow them; but fortunately there are still some places in this world not devoted to the *auri sacra fames*, and for these and their owners such plants are well suited. *F. Kranzlin, Berlin.*

ROSEHILL, FALMOUTH.

GARDENS situated on the southern shore of Cornwall are exceptionally favoured in the climatic conditions which they enjoy, so much so that, in visiting some of these sheltered retreats, one might almost imagine that they were as exempt from the rigours of winter as were the fabled "Fortunate Isles," in such vigorous health are the rare and tender shrubs and plants, denizens of all portions of the globe, that find sanctuary there.

The garden at Rosehill, the residence of Mr. Howard Fox, though not extensive, is very charming and replete with interest, for the planting has been tastefully carried out, and the fine collection of tender subjects that it contains leaves nothing to be desired on the score of health. The view from the front of the house is very pretty, the eye passing over the gently-sloping lawn, through a vista of trees, Cordylines, Bamboos, and Phormiums, to catch a glimpse of the sea's blue horizon-line in the distance.

Among the trees and shrubs I have noted the following:—*Abutilon vitifolium*, white variety, the finest specimen that I know of, 20 feet in height and as much in diameter; *Acacia armata*, *A. dealbata*, *A. lophantha*, rare in the open-air (it is 12 feet high and flowers through the winter); *Acacia longifolia*, bearing seed freely; *A. melanoxylon*, 30 feet in height; *A. verticillata*, *Olearia (Aster) argophylla*, with Musk-scented leaves, over 20 feet in height; *Berberis Bealei*, a bush of *Beronia megastigma*, 4 feet 7 inches high, that was in flower in the first week of last April; *Cerrea viminalis*, the handsome Peruvian *Cantua dependens*, 6 feet in height, as a bush in front of a wall; a large shrub of *Coronilla glauca* that flowers all the winter; *C. viminalis*, also a large bush; *Cordyline australis* in quantity, the largest being an immense specimen, with numerous heads and with a trunk circumference of 5 feet 5 inches at 1 foot from the ground. This is about 20 feet in height, and often perfects ten or more flower-spikes. The only example that will probably compare with this is one at Enys, forty-five years from seed, which has a girth of just under 6 feet. *Cytisus racemosus*, 12 feet high, generally blooms through the winter, as does *Cestrum (Habrothamnus) elegans*. *Datura sanguinea*, 10 feet in height and 18 feet through, often bears flowers as late as February, as does *D. flava*, 8 feet in height. *Desfontainia spinosa*, 7 feet high, blooms profusely, and bears seed. There are also present *Edwardsia (Sophora) microphylla*, *Embothrium coccineum*, which in a young state had curiously cut foliage; *Eugenia apiculata*, *E. Ugni*, *Eupatorium micranthum*, better known as *E. Weinmannianum*; *Eucalyptus cornuta*, which has borne seed; *Grevillea rosmarinifolia*, 8 feet across; *G. robusta*, in good health; *Leptospermum baccatum*, *Melia Azedarach*, 7 feet in height; *Myoporum laetum*, an Australian tree with lanceolate leaves dotted with countless transparent spots, bearing small, white, purple-spotted flowers, seeding freely here, height 15 feet; *Mitraria coccinea*, as a bush, 5 feet across; *Olearia ilicifolia*, *O. stellulata*, 8 feet high and 10 feet through; *Piptanthus nepalensis*, which here bears seeds; *Paliurus aculeatus* (the Calvary Thorn), *Pavia macrostachya*, *Phytolacca icosaandra*, *Pinus Webbiana*, *Pittosporum eugenoides*, *P. tenuifolium*, forming a hedge; *P. Tobira*, 20 feet in height, that often flowers through the entire winter; *Podocarpus andina*, *Ribes speciosum*, *Schinus molle* (Pepper tree), 9 feet high; *Skimunia japonica*, 6 feet in height and 8 feet in diameter, flowering and fruiting profusely; a great bush of *Solanum crispum*, the New Zealand *S. aviculare*, which has been out four winters unprotected, and bears purple flowers

2 inches across, followed by large, yellow, egg-shaped fruits, 7 feet 1 inch in height, and 7 feet 8 inches through; *Sparmannia africana*, almost a tree, flowering all the winter, and the rare *Taxodium pendulum*, also known as *T. distichum microphyllum*, and as *Glyptostrobos pendulus*. Another seldom-seen shrub that flowers well at Rosehill is *Viburnum rugosum*, from the Canary Islands. *Arundo donax* grows marvellously, some of the canes being fully 20 feet in height. *Asparagus Sprengeri*, *A. deflexus*, and *A. tenuissimus* are perfectly happy in the open ground, as is *Begonia*

Great bushes of *Fatsia japonica* spread their deeply-cut foliage over the lawns; Tree-Ferns, *Woodwardia radicans* and *Lomaria magellanica* show luxuriant growth, while the great arching leaves of the *Musa*; have a noble effect. *M. Ensete* presents a splendid appearance in the autumn, and for the last two years *M. japonica* has flowered and fruited. Of the latter species there are now four fine specimens about 10 feet in height. *Melianthus major* is 12 feet in height, and a bush of *Salvia leucantha* 5 feet high, while a mass of *Senecio Petasites*, fifty years of age, is

FIG. 36.—ROSEHILL, FALMOUTH.

metallica. Numbers of Bamboos are grown, all of which are in vigorous health. I was informed by Mr. W. Jenkins, the head gardener, that *Phyllostachys fastuosa* had in two weeks made 5 feet 9 inches of growth. *Clematis balearica* or *calycina*, and *C. cirrhosa*, two species often confounded, are growing on the same arched trellis, where the differences in their flowers and foliage can be easily noted. *C. montana* has ascended fully 30 feet into a tall *Cupressus macrocarpa*, and *C. Jackmani* has taken possession of an old Apple tree. Of *Crinum*s a clump of *C. Moorei* is 8 yards in circumference, and the flower-heads exceed 5 feet in height. A few years ago *Furcraea longæva* perfected a towering spike of inflorescence.

about 12 feet in height, and *S. Heritieri* and *S. grandifolius* are also grown. Hybrid *Hippeastrums* do well in the open, and a large bed of *Hedychium Gardnerianum* often perfects fifty flower-spikes in September. *Marica californica* increases from self-sown seed, and fancy *Pelargoniums* grow and flower freely. *Hypericum uralum* is 7 feet in height, and a great plant of *Sempervivum holochrysum* from Tenerife, with thirty heads of foliage, measures 5 feet by 4 feet. Three years ago I saw this plant in bloom, when the flower stems were 42 inches in height, and the golden flower-heads were 15 inches in length, and 43 inches in circumference. *Semele (Ruscus)*

androgyna, from Madeira, grows well, flowers and fruits. *Tacsonia mollissima* makes rampant growth over a portion of the house; *Trachelospermum* (*Rhyncospermum*) jasminoides flowers freely well into latest autumn, and *Rhodochiton volubile* proves perennial. On a sloping bank Persian *Cyclamens* are at home, and produce their scented blossoms in the spring, while at the same date another portion of the slope is white with countless flowers of *Triteleia uniflora*. In the first week of April the Citrons on the open wall were bearing full-sized fruits and flowers. At Rosehill the Mistletoe has found a rather uncommon host in a Mountain Ash. *S. W. Fitzherbert.*

ORCHID NOTES AND GLEANINGS.

ORCHID SEEDLINGS.

WE have already alluded to the curious interaction observed between certain fungi and certain Orchids, and we now add some further particulars taken from a report of M. Noel Bernard in the *Journal de la Société Nationale d'Horticulture*, May, 1905:—

I used, says M. Bernard, glass tubes closed with a wad of dry cotton, in which I placed a small piece of absorbent cotton soaked in nutritive liquid, and I sterilised these tubes in such a way as to kill all germs of mould or microbes. I sowed the seeds on a piece of damp cotton; for this purpose entire capsules not yet open were necessary, and the seeds were taken with every reasonable precaution not to sow mould or microbes of any sort with them. I was easily able to keep the seeds under these conditions for six or seven months without any mould developing. The Orchid seeds under these circumstances did not germinate at all, even in tubes placed in a greenhouse and in full light. As a rule the seeds swelled a little and turned green during the first few weeks, and then remained stationary. I have, for instance, some *Phalenopsis* seed which has been in this state for three and a half months. The small embryos that turned green did not exceed a millimetre (about $\frac{1}{5}$ inch), and they died some months later without further development.

To induce germination a fungus must be introduced into the tube; a species of mould formed of long white filaments, which I cultivated in a separate tube. As soon as the seeds come in contact with the threads of this fungus they begin to germinate. This is seen by comparing the above-described *Phalenopsis* seed with a second sown with the fungus at the same time; the young plants are in perfect condition and showing already the size of Peas.

In our hot-houses the circumstances are identical. If there is none of the fungus in the seed-pans the seeds do not germinate, and when seeds do germinate it is owing to the collaboration of the fungi. In looking at the little plants through the microscope, the filaments of the fungus are seen inside them. In introducing suitable fungi into seed-pans, as was done with the tubes, a certain and regular germination is secured, as M. Magne has found and reported.

Now, what is the particular fungus that is required? Is the same one suitable for all Orchids, or a special one for each? This question I have decided. I consider that the same description of fungus may cause many Orchids of different kinds to germinate. The *Cypripedium* fungus is also of use in the case of *Cattleya*, *Lælia*, and *Bletia*—that is to say, for Orchids whose germination is, as is well known, comparatively easily induced, and which are not very particular in their choice of a fungus.

But those Orchids which germinate with difficulty have special requirements. Thus, *Phalenopsis* will not germinate with the *Cypripedium* fungus, nor with that of the *Cattleya*, nor with

that of the *Odontoglossum*. They will only germinate with the *Phalenopsis* fungus; but this last-named is also suitable for the *Vanda*. Such is also the case even with the *Lælias*, for instance, which will germinate with one or the other of these fungi with more and with less success. Taking two young seedlings of *Lælia*, one germinated with the *Phalenopsis* fungus, the other with the *Cypripedium* fungus, and although both are of the same age, the former is seen to be more advanced than the latter.

Thus, in order to ensure success it is not sufficient to supply any fungus at random, but a special variety may be sometimes required for each species of Orchid.

At present the fungi are available which are requisite for the germination of species of *Cattleya*, *Lælia*, *Cypripedium*, *Phalenopsis*, and *Vanda*; it may also be said of *Odontoglossum*, as the fungus for this has also been discovered, but during the last six months I have not succeeded in procuring a fruit to make the experiment, the result of which I consider to be certain.

But before being certain as to all instances long and varied experiments are necessary.

For these experiments collaboration is necessary, and this M. Bernard solicits. M. Bernard does not tell us what the particular fungus is in the several cases he mentions. Probably he has not cultivated it up to the fruiting stage.

SALADS AND SALAD-MAKING.

CONTENTED should be the amateur living in the country who can go into his garden and cull the materials for his salads these warm summer days. In doing this it is advisable for him to choose the early morning hours, whilst all vegetation is at the coolest and dew-laden, in the case of Lettuces pulling the plants up and placing the roots till wanted in a shallow vessel of water in a cool cellar or pantry. And the various herbs may be likewise gathered, inserting the butt-end of the shoots in water.

The consumption of salads has enormously increased in modern times in England, not alone of "salted things," as of Lettuces, Radishes, Cresses, Celery, Onions, Beetroot, Chicory, Endive, and Cucumbers, but of the more elaborate "dressed" salads. Among Europeans the French, the German speaking nations, Italians, Bohemians, and Hungarians are gourmards in the matter of salads and adepts in their concoction, but too much addicted to the use of garlic as an ingredient in them to suit English tastes. A favourite salad with the Germans in the cold season is made with *Celeriac*, or Turnip-rooted Celery, which in that country of severe winters takes the place of the blanched Celery of our gardens. The tubers, which grow and develop on the surface of the soil and are moulded-up, are taken up late in the month of September, and after pulling off the larger leaves and leaving merely a rosette of heart-leaves, are embedded in sloping banks of earth formed in cellars, the rosette not being covered with earth, but left, so as to make a slight amount of growth.

Before being eaten the tubers are thoroughly cleansed from soil, the root-fibres cut off, immersed in a saucepan filled with cold water, and, like Beetroot, they are boiled till tender throughout, and then laid aside on a strainer to get cold. When required for use as a salad, the tubers are carefully peeled and cut into slices about $\frac{1}{4}$ -inch thickness before being placed in the bowl along with, perhaps, sliced Beetroots and cold Potatos. As with ourselves, Lettuces of the small Cabbage varieties, some of which are curiously spotted with crimson, are those most commonly consumed, the Roman (as the Cos varieties are called) not finding much favour, although they

have their uses in the kitchen, being stewed in a little strong soup with an accompaniment of shelled Peas, or the whole pods of the *sans parchemin* varieties, and the necessary condiments. Cabbage Lettuces, served simply with olive oil and white wine vinegar, are found on the table in most households and restaurants, and are eaten with either hot or cold meats.

In French households of the better class one does not find, perhaps, so much Garlic employed as a flavouring agent in salads as in Italy and Central Europe; nor is *Celeriac* so much in favour. Watercress and Radishes are abundantly employed, but not in mixed salads; and Endive, both mossy and the smooth-leaved Batavian varieties, are greatly liked, also Chicory similarly blanched by growing it in warmth in darkness. The so-called French Breakfast Radishes in all varieties are great favourites with our neighbours across the Channel, and are to be obtained during the greater part of the year. Blanched Celery is largely grown in those parts of the country enjoying mild winters, forming a considerable article of export to those countries which are too cold in winter to allow of its being grown. The French, like their neighbours across the Rhine, consume certain varieties of Potatos possessing a waxy consistency that allows of slicing without crumbling in the process. We have a few which can be thus employed—viz., the Walnut-leaved, Myatt's Ashleaf and the common Ashleaf, and the Fir-cone, a long, thin, blue-skinned tuber, now rarely met with in our gardens, which is of no value except as a salad Potato, or as a botanical specimen demonstrating the bud-like character of the tuber. There are various sweet herbs which no sensible maker of salads can possibly dispense with, and of these I will now mention the more important in common use abroad and in our own country—viz., Tarragon, a hardy, tall-growing perennial plant of easy culture in most soils, the young leaves good for mixing with green salads; Corn-salad, of which three or four sowings may be made in the summer, and which needs no blanching; various Cresses, as the Normandy or curled; the seed-leaves of Mustard and common Cress; young Onion plants when but 6 to 8 inches in height, sown at various times; the young leaves of garden Sorrel, and Lettuce, useful as a salad ingredient or as a garnish. Garlic, previously mentioned as being commonly used on the Continent, should never be employed excepting as a flavouring, rubbing the "cloves" of the bulbs in a little oil round the sides and bottom of the bowl, afterwards extracting any pieces that may have become detached in the process.

Cucumbers and Tomatos should not be omitted from the list, the latter having become a great favourite as compounds of a salad, either by themselves or mixed with other things, the Currant and Cherry-fruited varieties being especially nice.

A rule to be generally followed in preparing leafy salads is never to make use of a knife when the finger and thumb will answer the purpose of dividing the leaves into small pieces. Never, if it can be avoided, let leafy salads be left soaking in water, nor allow them to get wilted by exposure to the air. Strong vinegar should be diluted with warm water to an agreeable strength; it will mix better with the oil than when used cold. Salt should be sparingly used, and added to the salad at the last moment.

The best kind of Pepper for salads is the coarsely-ground black, which affords a fine zest to a salad, and is not so apt to cause choking as the finely-ground white Pepper. The oil should be the best Lucca; and, as the last word, the contents of the bowl should be thoroughly incorporated by a vigorous stirring with a wooden spoon or fork. *F. M.*

COLONIAL NOTES.

RAINFALL NEAR CAPE TOWN.

It may interest some readers of the *Gardeners' Chronicle* to know that the rainfall here for the month of June was as much as 23.20 inches. *Jas. Taylor, Head Gardener to A. Ohlsson, Esq., Montebello, Newlands, near Cape Town.*

MISLETOS IN NEW ZEALAND.

Thinking that readers of the *Gardeners' Chronicle* may be interested in the subject, I send you an account of some of our Missetos (*Loranthus*), notably one that grows readily on many sorts of trees in this central part of North Island. It forms large bunches of foliage and shoots on the limbs of the foster-parent, the shoots being covered with crimson flowers about the size and shape of those of a Myrtle. It is very conspicuous when in flower. Imagine a huge bunch hanging in the centre of a lot of other foliage covered with the crimson flowers! The berries are scarlet, viscid, and the leaves are rather broader than those of the English variety. Another sort has greenish-yellow flowers and berries. It is very hardy, growing on many varieties of native trees; but I wish to draw attention to its having adapted itself to European fruit-trees, including the Plum, Pear, &c., also to the pseudo-Acacia. I have seen it in the South Island orchards as well as here. There are many sorts of Misseto which are natives of this country of which you will probably receive descriptions later [Many thanks]. We have a Poplar-tree here that was erected in honour of King Edward VII.'s accession to the throne. It was cut and erected as a flagstaff about 50 feet high, and to our great surprise it started and grew, and is now well feathered with shoots—truly a loyal tree, and probably the biggest readers ever heard of which made roots as would a cutting of *Pelargonium*. *Joseph Mayo, Tokaanu, Lake Taupo, New Zealand.*

FORESTRY.

THE LOCUST TREE.

MAY I just say that my letter on this subject had reference exclusively to growing the Locust tree in Britain as a crop, and had nothing to do with German woods or coal mines. Can Mr. Booth answer my questions on that head? As to the Douglas Fir, no one expects a greater future for the tree than I do, but "at present," as I said, timber dealers regard it as a Spruce. As sold standing I should like to know how much more Mr. McCorquodale got per foot for his Douglas (after felling, hauling, and all expenses were deducted) than good Spruce was fetching at the time. I put this question when the article appeared in the *Perth Constitutional*, but got no answer. The price of the timber standing in the wood is my price, not the delivery price. The comparative dimensions given by Mr. Booth of Larch and Douglas are no doubt correct. Lately sections of beautiful Douglas forty years old were shown in the forestry section, Park Royal, as big as Larch at 100 years, as the two examples from Lord Powis's estate, I think, showed.

Some of the most ugly and mis-shapen trees in the London squares and suburbs at present are Locust trees—what timber merchants would call "brutes." *J. Simpson.*

— There can be no doubt that the Locust tree (*Robinia*) grows equally well in France, Britain and in Germany. And all that has been said in my different letters about the wood applies as well to British-grown woods and to British coal mines as to our German forests.

Ugly and ill-formed specimens of the Locust tree, such as are to be seen in the London squares

and suburbs, and which timber merchants call "brutes," may be found also on the continent. We see everywhere "brutes" of Pines, Firs, Oak, Beech, &c., without condemning the species on that account. So it is with the Locust tree. If I had 1,000 acres of this tree in England, and the English timber merchants combined to discredit the value of the wood and not to buy it, I could very likely not make any use of it, but in the absence of such an unexpected opposition my

CATTLEYA AMETHYSTOGLOSSA.

This pretty *Cattleya* is frequently seen in gardens bearing the name *C. guttata* Prinzii, the error having been made by Reichenbach in *Bonplandia*, iv., p. 327, and adopted by some authorities. There is no doubt however that it is a distinct species, and one of the most beautiful of its section. It is a native of Bahia, and its fine wax-like flowers have the sepals and petals vary-

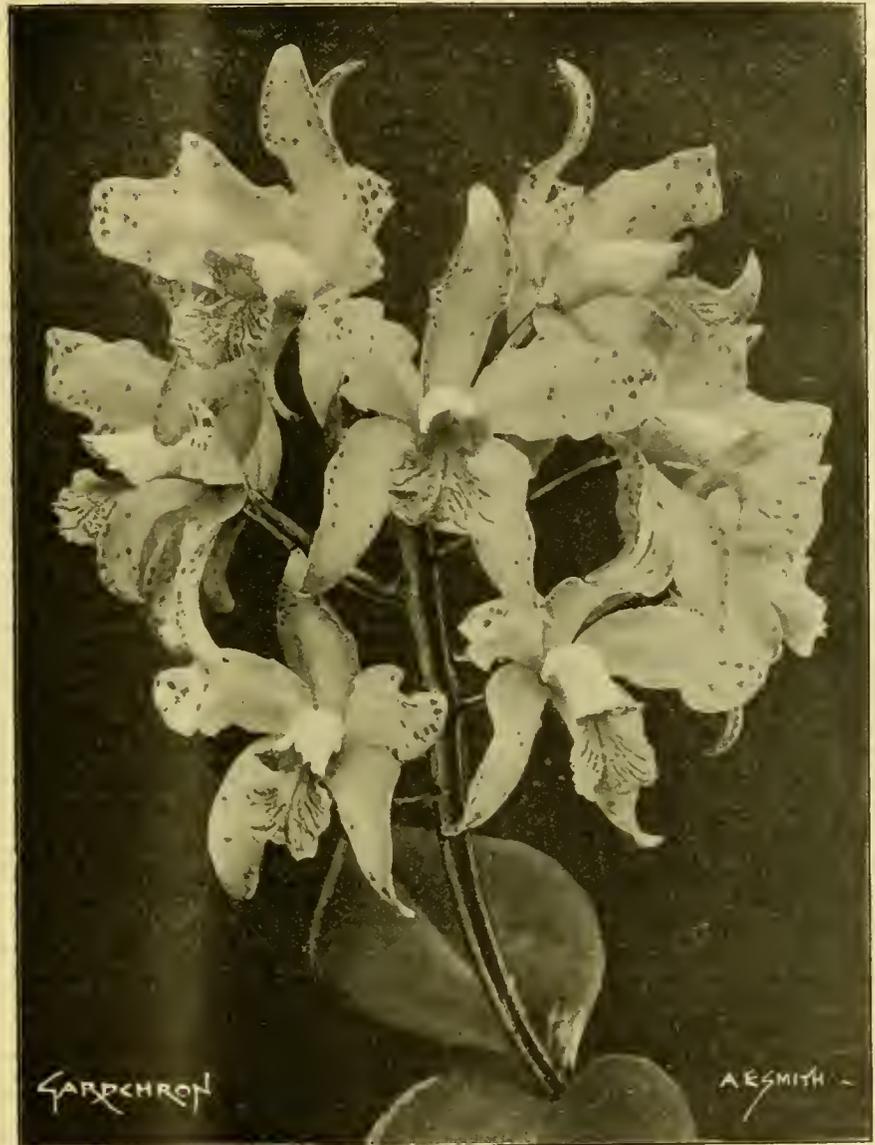

FIG. 37.—CATTLEYA AMETHYSTOGLOSSA.

answer as to German and French-grown wood of this tree is equally applicable to English-grown wood.

As to Mr. McCorquodale's thinnings of the Douglas, Mr. Simpson overlooks that when Larch and Douglas fetched 1s. per foot the Douglas Fir was only half the age of the Larch and stronger, and contained more than double the number of cubic feet that the latter did. The thinnings brought this price at a public sale, not standing in the wood; the price was delivery price. The prejudices of the timber merchants must be overcome; but here is the trouble—we want to sell wood which is unknown to them. *John Booth, 39, Mozartstrasse, Gross-Lichterfelde, Berlin.*

ing from yellowish-white to light rose spotted with purple, the labellum, which bears numerous raised lines, being of a rich amethyst-purple.

Cattleya amethystoglossa is of very easy culture in the intermediate-house, provided a distinct dry season of rest be given.

PLANT PORTRAITS.

PYRUS MALUS NIEDZWETZKYANA.—*Bulletin d'Arboriculture, &c., July.*

PEROWSKYA ATRIPLICIFOLIA, André, in *Revue Horticole*, July 16. A western Himalayan shrub of the Labiate family, with grey lanceolate leaves and small blue flowers in spikes, as in some *Sativas*. Useful for summer bedding.

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and General Summary, ante, pp. 81-87.)

O, SCOTLAND, N.

ORKNEYS.—The poor appearance of the fruit crops this year is due to frost towards the end of May. At the beginning of the season there was every sign of an excellent crop of all kinds of fruit. *Thos. MacDonald, Balfour Castle Gardens.*

SUTHERLANDSHIRE.—Gooseberries have done better than was expected, as the frost and snow showers early in April when the bushes were in bloom threatened at the time to spoil the crop. There was a moderate amount of bloom on Apple trees, and no frost interfered with the setting, but they set badly nevertheless, and the crop is very much below average. The soil is of sandy loam, and is of good depth. *J. Melville, Dunrobin Castle Gardens, Golspie.*

I, SCOTLAND, E.

ABERDEENSHIRE.—There was plenty of blossom on Apple trees, but the crop is poor, and several of the trees have none. All sorts of small fruits are good crops, except Gooseberries. Black Currants and Raspberries are very abundant. The soil is a medium loam on a hard pan subsoil. *Jas. Grant, Rothienorman Gardens.*

— The prospects of good hardy fruit crops were very promising in early spring, when every tree bore a mass of bloom. But the late frost and the long-continued drought have ruined them. All the fruit-trees are infested with insects. Caterpillars have done much damage to Gooseberry bushes. All crops are sorely in need of rain. The soil is stiff and heavy and rests upon clay. *John Brown, Delgaty Castle Gardens, Turriff.*

BANFESHIRE.—The fruit crop gave every appearance of being abundant. Blossom was plentiful on Apple, Pear, Plum, and Cherry-trees, but during the flowering stage the weather was very cold and there were cutting winds, in consequence of which the crops are very thin, especially the finer varieties of Plums on walls. Victoria Plums on standard trees are satisfactory. Pears are under average. Apples are a good half crop. Cherries are fairly good, especially Morellos. Rain is wanted badly. *J. Fraser Smith, Cullen Gardens.*

CLACKMANNANSHIRE.—The Apple blossom was destroyed by rain. The soil here is irregular, being partly stiff and partly light. *A. Blackwood, Academy Gardens, Dollar.*

FORFARSHIRE.—The fruit crops in the gardens here are moderate. Apples promised well when in flower, but the flowers set irregularly, and the crop is not an average one. Plums are mostly grown on walls, and have required a good deal of thinning, the set being abundant. Small fruits are an average crop, but owing to the very dry summer Strawberries are below average. *W. McDowall, Brechin Castle Gardens.*

HADDINGTONSHIRE.—Apples are almost a failure, the blossom having been distorted to a very large extent, and scarcely any set. Other crops are fairly good, but none is superabundant, though Strawberries, Gooseberries, and Raspberries, since the rain, have swelled up to very large crops. Our rainfall in 1905 up to July 14 was just over 6 inches. It is not improbable that other causes than cold are responsible for the failure of the Apple crop (p. 81). Here, for instance, we escaped the severe frosts that were common when the Apple blossom was mostly cut. Yet with the exception of 1880 the crop is the smallest I can remember. It was quite clear to me at the time of blossoming that the chance of a crop was

small indeed, and a visitor who came on purpose to see the Apples flourishing was quite sceptical when I pointed out the slight chance there was of a set. Much of the blossom was contorted in the petals, many of which too were incomplete, and quantities of the blooms were devoid of ovaries and stigmas, while the anthers in many instances were aborted and incapable of producing pollen. As to why this condition existed, I think the abnormally dry summer, autumn, and winter of 1904 were the sole cause. Ground that was trenched 2 feet deep in October was absolutely dust-dry. That these conditions remained till long after the flowering season of Apples is certain from the abnormally low rainfall, and the ground was still so dry after the fall of an inch early in July that the soil about some Evergreen Oaks I tried to transplant was found, all except a few inches on the surface of the soil, to be so extremely dry that the attempt to lift them had to be given up. I think, therefore, that the failure of Apples, at least in some instances, is due, if not solely, at least to a very large extent, to the exceptionally severe drought, which elderly people have been comparing with the year 1826, of which they heard accounts from an earlier generation. Why Strawberries, Gooseberries, and other small crops have been a success may be attributed to the roots getting the full benefit of any rains that fell. It is rather curious that the Apples that are bearing here are not late but early-flowering sorts, and though Peaches and Apricots were hard frozen a sufficient number escaped to produce a good crop of these. *R. P. Brotherton, Tynninghame Gardens, Preston-kirk.*

— Small fruits in this district are again heavy crops and of first-rate quality. There was a profusion of blossom on all other fruit-trees, but the quantity of fruit that set is far below the average. Insect pests were very numerous early in the season, and did great damage to Apple and Pear-trees in cases where no measures were taken to destroy the pests. *William Galloway, Gosford Gardens, Longniddry.*

MIDLOTHIAN.—The fruit-crop is very disappointing. All kinds of fruit-trees showed a great abundance of blossom, and during the flowering period the weather was very dry, with constant east winds and very cold nights, resulting in many of the trees not setting any fruit. Only early varieties of Apples and Pears have a crop. There is a moderate crop of Victoria Plums. All small fruits are good crops, and after an unusual drought the rain came in time to save them. The soil is light, and the subsoil gravel. *James Whytock, Dalkeith Palace Gardens, Edinburgh.*

PEEBLESHIRE.—Apples are a failure here this season owing to spring frosts. The blossoms were destroyed even before they opened. Plums are scarce through the same cause. We have fine crops of Cherries, Strawberries, Raspberries, Gooseberries, and all small fruits, and as the bushes are all young and healthy they are of good quality. The soil here is light, good, and deep, with a gravel sub-soil. *W. Young, Stobo Castle Gardens.*

PERTSHIRE.—The spring frosts spoiled a great amount of blossom on Apple and Pear-trees in this district, the appearance being exceptionally fine at the time of flowering. Small fruits have suffered from want of rain. The soil in this district being of a heavy loam has withstood the drought well. *J. Farquharson, Kinfauns Castle Gardens.*

— Insect pests of all sorts have been unusually bad this season. *James Ewing, Castle Menzies Gardens, Aberfeldy.*

6, SCOTLAND, W.

ARGYLLESHIRE.—Apples and Pears are a poor crop. There was a superabundance of fine

blossom, but at the time of flowering we had cutting winds. Strawberries and small fruits are very abundant and of first-rate quality. The soil is a light sandy loam. *D. S. Melville, Pottallock Gardens, Lochgilphead.*

AYRSHIRE.—The fruit crops are all under average, and in some gardens they are a total failure. Black Currant mite has destroyed all the crop of this fruit in this garden. This is the driest summer we have had for many years, and insect pests of all kinds have been very destructive to fruit crops. *W. Priest, Eglinton Gardens, Kilwinning.*

DUMFRIESSHIRE.—Apples and Pears this year are a very thin crop in our district. Early in the season fruit trees with us looked exceedingly well, but a cold "snap" did terrible damage on the mornings of May 18, 19, 20, 21, and 22, when in the gardens here we registered 7°, 8°, 11°, 10°, and 6° of frost respectively, followed by cold, damp evenings, with slight frosts in the mornings. This continued till June 1, but since that date we have had very warm, dry weather, with an unusual amount of bright sunshine. We have Strawberries, Raspberries, Currants, and Gooseberries of first-class quality, although in no individual case is the crop a heavy one. *John Mackinnon, Terregles Gardens, Dumfries.*

— Strawberries are an excellent crop and of good flavour. The rain came just in time to save the crop. We apply heavy mulchings with rough stable manure, which suits Strawberries in our light soil, it also keeps the fruit clean after being washed with rain; we put it on early in spring. In our experience results are better from digging between the rows with a four-pronged fork, instead of with a spade in autumn. Apple trees flowered profusely and expectations were high, but 6° and 7° of frost on May 23 and 24 ruined the crop. Apples are almost a total failure, there being only a few fruits on wall trees. The soil is a light sandy loam. *Jas. MacDonald, Dryfeholm Gardens, Lockerbie.*

KIRKCUDBRIGHTSHIRE.—I have no the least doubt but the Apple crop would have been a good one but for the severe frost we had on May 23, when all the trees were in blossom. *N. Macfayden, Glenlie Gardens, New Galloway.*

RENFREWSHIRE.—There was a fair promise of blossom at first, March being mild though wet April was cold and sunless, with sharp frosts, which thinned Gooseberries and Currants considerably. The month of May until May 23 was remarkable for withering winds and frosty nights. *Jno. Methven, Blythwood Gardens.*

WIGTOWNSHIRE.—Bush-fruits and Strawberries are heavy crops, and in size and quality they are equal to former years. Apples, Pears, Plums, and Cherries are light crops, owing to the long-continued east winds and frosts during May. The soil is a moderately deep friable loam; the situation is low and well sheltered. *James Day, Galloway House Gardens.*

2, ENGLAND, N.E.

DURHAM.—Apples, Pears and Plums are under average owing to the cold winds from the sea causing the fruits to drop soon after setting. Black Currants are scarce, which is due to the blight of last year, which caused the leaves to fall in July. Strawberries are poor owing to the very dry season. The soil is a dry limestone. *R. Draper, Seaham Hall Gardens, Seaham Harbour.*

— The fruit crops this year on the whole are considerably below the average, owing chiefly to the severe frosts in the early part of April. We have a strong clay soil, and the want of rain in this district cut short the Strawberry crops. *Jas. Noble, Woodburn Gardens, Darlington.*

— With the exception of Strawberries and Gooseberries, all other hardy fruits are much

under average. Our garden stands high and is somewhat exposed, consequently the trees suffered very much from north and east winds, which prevailed more or less all spring, particularly during the blossoming period. The long-continued low night temperatures and frosts, lasting till the end of May, caused the destruction of what promised to be a fair average crop. *J. Machar, Snell House, Howden-le-Wear.*

YORKSHIRE.—The fruit crops are unsatisfactory, Apples, Pears, and Plums are very poor. There was very little blossom on Apple trees; some varieties of Pears on walls are good, but all fruit trees are suffering much from the long drought. Strawberries are very good on young plantations in some situations. Fruit trees were damaged by the severe frosts in May, Potatoes also were damaged by the frost. The soil varies much. The subsoil is chalk on the hills and clay in the valleys. The fruit crops on the hills are dried up. The Loganberry seems to stand the dry weather better than anything, there is an excellent crop of fruits, which are in great demand for tart and jam making. Apricots and Plums in a glass shed are carrying good crops of fruit, and show what is required to grow satisfactory crops of these fruits—a warm situation with good soil. *Bailey Wadds, Birdsall Gardens, York.*

— With the single exception of Strawberries the fruit crops are very light hereabouts. This remark is particularly applicable to stone fruits. Apples are a very thin crop; Lord Suffield, Keswick Codlin, and the old Yorkshire Greening are the only varieties that have any fruit on worth mentioning. Of Pears, Comte de Lamy, Louise Bonne of Jersey, Jargonelle, Summer Franc Réal, and Olivier de Serres have thin crops. *H. J. Clayton, Grimston Park Gardens, Tadcaster.*

(To be continued.)

KEW NOTES.

ALLAMANDA.—This genus is well represented by many profusely-flowered specimens in various houses at the present time. The largest and best plant is that of *Allamanda Schottii* var. *Hendersoni*, flowering on the roof of the Palm-house, and which may be seen best from the gallery. It is planted in one of the beds and trained up a pillar on to the roof. It is never dry at the roots, nor ever quite denuded of its foliage. In the early spring the branches are shortened, but not pruned hard back. Under such conditions it produces enormous growths, some of which are probably from 40 to 50 feet from the root-stock. From April until November the plant produces a great profusion of flowers, such as is never equalled when grown in a pot. The flowers are large and yellow, with brown markings in the throat. *A. Williamsi* is also in bloom in the same house, where it grows and flowers very freely, covering a large area of the roof; the blossoms are about two-thirds the size of *A. Schottii*, and much the same in colour. On the stage at the south end of the Palm-house is a specimen of the bushy *A. cathartica*, which is the smallest-flowered species grown at Kew. The flowers are about the size of those of a small *Gloxinia*, light yellow in colour, with rounded segments. *A. neriifolia* is a closely allied species, deep in colour, rather larger in the flower, and has acute segments. This species is represented in the Mexican-house by a bushy plant about 3 feet in height. Several plants of *A. grandiflora* are making a fine display in the stove. Although the flowers are smaller than those of the *A. Schottii* type, the beautiful bright, clear yellow of the blossoms fully compensate for what they lack in size. *A. violacea* is also to be seen in the same house, having flowers about the size of *A. Williamsi*, but of a violet-purple colour, being very distinct from all the other members of the genus, and one which

should be more widely known and cultivated. *A. Schottii* var. *magnifica* is a fine form, with very large yellow flowers, but unmarked in the throat. It is flowering in the Begonia-house. *W. H.*

ROSE-GARDEN AT LUSCOMBE.

THE illustration at fig. 38 represents the Rose and rock-gardens at the residence of Peter Hoare, Esq., Luscombe, near Dawlish, in South Devon. The beds are planted with the choicest varieties of Tea and hybrid Tea Roses. Surrounding the beds there are rambling Roses trained on chains, where such varieties as Turner's Crimson Rambler, Queen Alexandra, Dundee Rambler, Euphrosyne (a very pretty miniature pink Rose), Perle des Jardins, Pink Gloire de Dijon, and Agara, make a very pretty effect.

On the rockery, which may be seen in the illustration, many somewhat tender species of plants are cultivated successfully. *Coronilla glauca* and

SOUTHWOOD, BICKLEY.

[SEE SUPPLEMENTARY ILLUSTRATION.]

THE village of Bickley, in Kent, is on the south-eastern fringe of London's vast suburbs, for hereabouts the great city becomes merged with the cornfields and the woodlands until the country nature of the district holds full sway, and the fruit plantations, for which Kent is so justly famous, become numerous. As the radius from the metropolis extends, so does the area available for large and beautiful dwellings; and Bickley may truly be said to consist of a collection of charming homesteads, comprising large and delightfully-arranged gardens and grounds.

Of such a one is Southwood, the residence of A. E. Baddow, Esq., with its ten acres of gardens and grounds, with flower-beds and borders, conservatories, pergolas, rock-gardens, and ornamental water, the last-named of which forms the subject of our Supplementary Illustration. For the

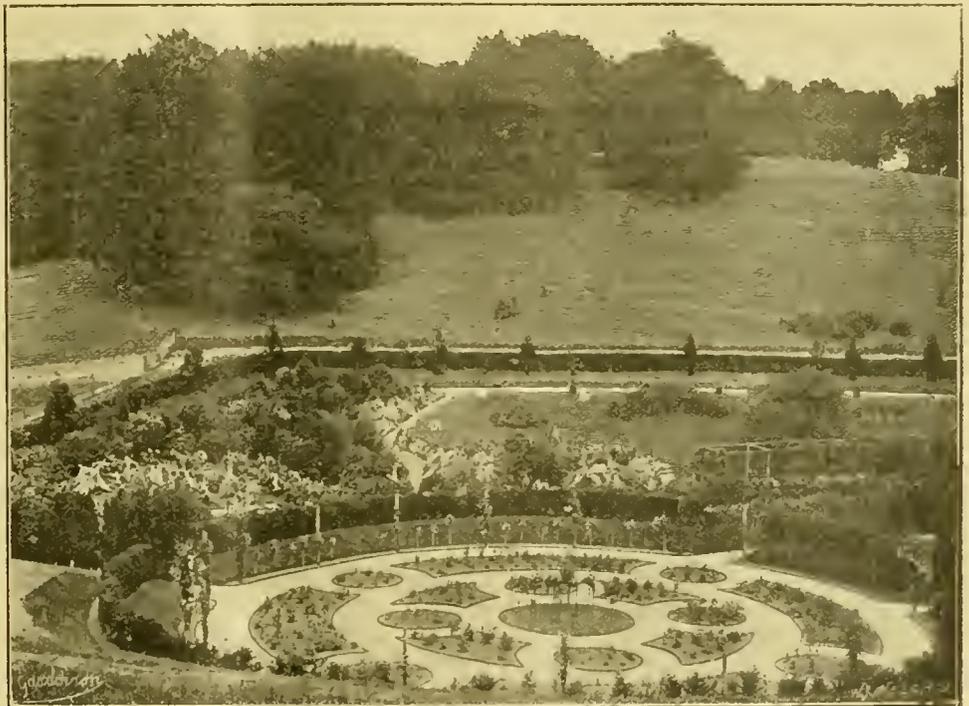

FIG. 38.—VIEW IN THE GARDENS AT LUSCOMBE, S. DEVON.

Cytisus fragrans are hardy during winter. *Clianthus puniceus* makes a fine show from the beginning of April until the end of June, and is likewise hardy. *Fabiana imbricata*, *Olearia stellulata*, *Lupinus arboreus*, and numerous other flowering shrubs and rock plants have made good specimens here.

Luscombe Castle is situated in one of the most beautiful localities in Devon, and from the Rose-garden a very lovely view of the sea is obtainable. We are indebted for our illustration to the head gardener at Luscombe, Mr. R. Seaborne.

NICOTIN—POISON.—At Reigate recently a seedsman was summoned for infringing the law requiring the word "Poison" to be placed on vessels containing certain dangerous substances. In the present instance the quantity of nicotin proved to be contained in a bottle of XL-All liquid was sufficient to cause the death of at least seventy-five persons, but there was no label indicating that it was a poison, and other requirements of the law had not been complied with. A fine of £3 and costs was imposed, or in default fourteen days. We believe that the word "Poison" is now affixed to the bottles.

photograph whence this was taken we are indebted to Messrs. Pulham & Son. The dwelling is a large modern house, commanding a view of the gardens and grounds from an elevated terrace, which has been made the most of to accommodate flower-beds and borders, set off here and there with such subjects as Roses, ornamental Conifers, and flowering shrubs. The house may be said to literally stand in the garden, for the flower-beds and borders encroach to the very walls, up which climbing and trailing plants, such as Roses, Wistarias, *Ceanothus thyrsiflorus*, *Spiræas*, &c., have been trained.

A large winter-garden forms an adjunct to the residence, and from which it is entered. This structure forms a cool and pleasing retreat, and has been laid out in the manner of a rock-garden or fernery; indeed it largely partakes of the latter character, for Ferns abound on every side, and from the way in which they luxuriate seem quite at home. Ferns do not entirely occupy the structure, but share it with such things as *Camellias*, *Phormium tenax*, *Gloire de Dijon* Roses, *Ficus repens*, *Clianthus puniceus*, *Clematis*, &c. One specimen of *Ficus repens* was extremely interesting. It had accommodated

itself on a plant (now dead), probably a Myrtle, and when several feet high had assumed the arborescent form, and was fruiting freely, the strong upper growths being so unlike the graceful climbing sprays that it was difficult to recognise them as belonging to one and the same plant. A fountain and water-pool add further charms to this place, and in the area covered by the spray of the water mosses and Liverworts grow undisturbed, furnishing the rockwork with a pleasing carpet of greenery. To the right of this structure is an admirably constructed rockery, which even at this season is bright with many plants in flower. The rock-garden terminates in a water-pool—quite a wild spot, given over to the numerous British aquatic and bog plants that have established themselves in its vicinity, together with others that have been planted, such as Bamboos, *Osmunda regalis*, *Equisetums*, *Iris*, *Spiræas*, *Astrantia major*, *Myosotis palustris*, and many others. In the pool itself was a batch of the common Water-Lily flowering grandly.

Passing by beds of Roses and an arcade of these same flowers, the walk is interrupted by a stream that is crossed by stepping-stones. The water flows from a dripping-well, and trickles down past hardy Ferns, which have taken advantage of every crevice and ledge in which to ramify, and nowhere could they succeed better. This stream supplies the ornamental pond seen in our picture, which is a delightful piece of artificial water. The bridge spans the pond at about its centre, so that the lake is really of much greater area than would be imagined from the view we give. *Wichuraiana* Roses are interlaced between the rustic wood-work of the bridge, the view from which is excellent. A small island finds a place in the water at the background of our picture; this is planted with Yew-trees and Pampas-grass, several clumps of which are also planted around the pond.

The banks of the pond are bright with *Iris*, species of *Lysimachia*, Brambles, *Yuccas*, Bamboos, *Phloxes*, and numerous alpine and rock-plants, which have been planted wherever opportunity has afforded. There are also clumps of *Nymphaea alba*, the hardy Water-Lily, in the margin of the water itself. Additional charm is added to the surroundings by beds of *Azaleas*, and trees and shrubs with ornamental foliage, such as *Acer Negundo* and the golden-coloured species. We admired the healthy appearance of *Bambusa Simoni aurea* and the well-developed colour of its handsome foliage.

Passing the well-kept lawn, in one side of which a series of flower-beds in the form of a star has been cut, one arrives at a shrubbery that contains some remarkably fine examples of Holly trees. Sufficient space has been allowed to permit the inclusion of herbaceous plants in the foreground of the border, which at the time of our visit was bright with the many flowers in season. Herbaceous flowers are grown around the borders of the fruit and vegetable garden, which also includes an extensive border of Roses, that furnishes cut flowers for decorative purposes in the mansion. The fruit trees, unfortunately, are almost bare of fruit, a feature we fear only too common in gardens this year. Plum-trees were carrying satisfactory crops, their blossom having escaped injury from the disastrous late frosts; but with this exception there will be little fruit to harvest.

There are several good glasshouse, vineries, Peach-houses, conservatory, stove, &c. The plant-houses are filled with such subjects as are useful for decorative purposes in the residence or for furnishing cut flowers. One may truly say there is a little of almost everything, including *Orchids* and *Nepenthes*. A batch of *Gloxinias* reflected credit on the gardener, Mr. E. Quantrell, who has been charged with the care of these grounds and gardens for the past ten years.

The Week's Work.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Peaches.—Continue to syringe daily all trees that have been cleared of fruit, giving them an occasional syringing with Quassia-extract or some other approved insecticide. Apply to all trees that appear to require it the same generous treatment with liquid-manure and other stimulants after the fruits are gathered as before. Do not be guided by the surface-soil appearing wet, which may be caused by the syringing, but examine the soil near the roots, and if it is dry apply water in quantity. Houses containing trees with fruits that are ripe, or approaching to that stage, should be ventilated rather more freely. Direct syringing of the fruits should be discontinued, but the stems of the trees, the surface of the walls, and other available spaces should be damped at least twice daily. Trees which are now swelling up heavy crops of fruit will require applications of liquid-manure and other stimulants, although the borders are well mulched with rotten manure. It is much better to feed the trees liberally at this stage, even if they are making too much growth, than to starve the fruits, because the roots can be easily lifted in the autumn and pruned if necessary. See that the fruits are fully exposed to the sun by keeping the leaves drawn aside, for highly-coloured fruits are so much superior to others. As soon as the fruit has been gathered remove all the shoots that are not required for furnishing the trees, and lose no time before syringing them vigorously with water, ventilating the house to the fullest extent.

Houses containing Later-ripening Trees.—Pinch the laterals, tie down and regulate the shoots as they advance in growth, and allow plenty of space between them to permit of full development. Remove altogether any gross shoots which interfere with the proper extension of the trees. If syringing is vigorously carried out and the borders are well mulched and kept supplied with nourishment, red-spider will not make much headway. Follow the directions given in the preceding paragraph as to syringing and feeding the trees, and exposing the fruits when they approach to maturity. See that young trees are well syringed and supplied with water; also examine any ties which may be too tight, or they will cause "gumming" in the stems at a later season.

Shading.—Many gardeners have a strong objection to shading fruits. It is, however, much better to lightly shade Melon and Cucumbers (in some districts) from the midday sun when it is as hot as it has been recently. This will help to keep the foliage clean and healthy, when better fruits may be expected from the plants than would be the case if the leaves were scorched. It may be advisable to shade other fruits with a thin coat of limewash or with $\frac{1}{2}$ -inch netting if the foliage has become thin from any cause whatever.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Pclargoniums.—As these plants pass out of flower, let them be removed to a position in the open garden where the sun's rays will reach them and ripen the wood thoroughly previous to their being pruned. Sufficient water only should be afforded them to prevent the foliage dying off too quickly. Cuttings may be taken when the wood is in a moderately hard condition.

Primulas.—The earliest batch of these from seeds should be ready now for potting into 6-inch pots. Let the compost to be employed for the purpose consist of two parts loam, one part rotten leaf-soil, and an equal proportion of silver-sand. Good drainage by means of broken crocks, charcoal or clinkers is very essential to success. The plants after being potted should be stood in a cold frame as near to the light as possible. Keep the atmosphere of the frame rather close for a few days, and shade the plants, but afterwards a free circulation of air should be

permitted, and during warm nights the lights may be removed entirely, allowing the dew to fall on the plants.

Primula kewensis ×.—The earliest propagated plants are making much headway, and a weak application of sheep-manure water should be given them. Allow a free circulation of air among the plants. Plants propagated later should be ready now for being potted on.

Cinerarias.—Let the plants raised from a late sowing be repotted when they are ready, employing a similar compost to that advised for *Primulas*.

Poinsettias.—No time should be lost in getting the later-struck cuttings potted into 5-inch pots. Those that have been potted for some time and are rooting freely should be afforded more air, and must be kept in a position near to the glass to prevent them becoming drawn or weakly.

Mignonette.—Make another sowing to follow the earlier sowing, which should be ready now for repotting into larger pots.

Humea elegans.—Pot up the seedlings into small 60-size pots from the seed-pans as soon as they are large enough, and place them on shelves near the light in a warm, moist atmosphere.

Carnations H. J. Cutbush, Cecilia, and Lady Mini.—For effective grouping in a corridor or conservatory the three varieties mentioned are of the best, and they are easily cultivated. For providing plants to flower next June and July, let those now passing out of bloom be layered as advised in a previous Calendar, and when they have made roots pot the plants up into 60-size pots, shifting them again into 6-inch pots when they are ready for these.

THE KITCHEN GARDEN.

By W. FIFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Winter Spinach.—When Spinach for winter use is sown very early the plants generally develop too quickly, with the result that flower-stems are formed. To have this vegetable in good condition during the winter and early spring months, sow seeds from the beginning of August to the end of September upon soil well prepared previously, and if the situation is sheltered for the latest crop all the better. Sow the seeds in drills 2 inches deep and 18 or 20 inches apart, and apply water to the soil before sowing the seeds. Occasional sprinklings of soot will help to keep wire-worms from destroying the roots. The prickly Spinach is the one generally sown for winter use, but with the summer or round-seeded variety equally good results may be obtained. I was asked the other day when Spinach was fit for use, the enquirer's crop being then running to seed. When the leaves are large enough nothing is gained by allowing them to remain on the plants. Young leaves are much superior to older ones. The practice of picking a leaf here and there is not so good as making a clean sweep of all leaves that are fit for use. The succeeding crop will then follow in that order.

Seakale is practically in use for six months out of the twelve, and for that reason is deserving of marked attention. The task of producing good, medium-sized crowns is simple when propagation is effected by cuttings. Let the surface-soil be hoed frequently amongst the plants. Apply occasional dustings of soot, and afford a good supply of water.

Coleworts for Autumn and Winter use should now be planted, and even if the weather is dry the work must not be delayed. On the day before planting is done, however, the ground should be well saturated with water. Allow a distance of 15 inches between the lines and 12 inches from plant to plant.

Peas.—Without a good supply of water upon the vine and at the roots some difficulty will be experienced in keeping up the supply. We have just completed staking our latest crops, which look remarkably well, due in a great measure to the "revolving sprayer," which is kept at work during the night to provide a very fine spray upon the plants and their surroundings.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Standard Apple-trees.—Examine the trees, and if there are any on which the fruits are too numerous, thin out the clusters. Do not allow a crop to remain on young trees that will weigh down the branches, causing them to break or split off. This can be prevented by removing the fruits from the extremities of the branches, or by affording support to those kinds which habitually fruit on the ends of the shoots. Early varieties of Apples, such as Irish Peach, Mr. Gladstone, Beauty of Bath, &c., should not be allowed to become too ripe before gathering, otherwise the flavour will be impaired. By keeping the fruits in a cool fruit-room for two or three days the flavour will improve. A few of the American varieties are much improved in flavour by being grown on a wall. Washington, King of Tompkins County, Northern Spy, Melon Apple may be counted among them. Remove all shoots that cross each other in standard trees, and any others that are unduly taking the lead should be stopped. Securely fasten all trees to prevent the westerly winds and equinoctial gales from swaying them about. Let trees which have been chafed by rubbing against their stakes be treated on the affected parts as a preventive against American Blight attacking such wounds.

Ornamental Crabs, such as John Downie, Mammoth, Siberian and Transcendent, so useful for making jellies, may have the fruits lightly thinned where the crop is too heavy. These Crabs are liable to overcrop themselves.

Hardy Vines growing on Walls.—Stop the laterals at one leaf and the leading shoots at two leaves beyond the bunch of fruit. Shoots that are intended to cover bare spaces should be stopped when they are 4 feet in length. Expose the fruit to full sunlight and thin the bunches moderately to get increased size in the berries. If mildew is noticed promptly syringe the Vines, on two evenings each week until the pest has been checked, with sulphide of potassium, at the rate of $\frac{1}{2}$ -oz. to each gallon of soft water, afterwards syringing the Vines with clear water.

Quinces and Mulberries should be thinned early. The size and flavour of the fruits may be much improved by applications of manurial stimulants to the roots.

Stirring the Surface-Soil.—Let the surface-soil in all fruit plantations be stirred periodically. Although this work does not compensate for lack of watering, yet if time cannot be spared for applying water, frequent hoeings will do much good.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Sobralias are usually stigmatised as worthless on account of the fleeting character of their blooms. But this fault, if fault it be, is compensated for by each flowering reed producing four or five blooms in succession, thus providing us with fresh flowers instead of one of diminishing beauty. Most species may be grown together in an intermediate compartment that is not heavily shaded, but is rather freely ventilated during the late summer and early autumn months. A few selected species and hybrids will produce a succession of flowers from March until October, commencing with the various forms of *S. macrantha*, of which the lovely pure white *S. m. Kienastiana* or *alba* is the gem, followed by *S. x Veitchii*, *S. leucoxantha*, *S. xantholeuca*, *S. Wiganii*, *S. Wilsoni*, *S. Lucasiana*, *S. pulcherrima*, and others. When potting these plants it is desirable to afford them large-sized receptacles, so that further shifting will not be needed for a number of seasons. Specimens that have become inconveniently large may now be turned out and cut into sections with a spade or edging-iron, it being useless to attempt to separate or disentangle the mass of thick, fleshy roots. Place them in the desired receptacles to the proper level, with crocks beneath and around to about half their depth, filling in to near the rim with a compost consisting of one-fourth part of good fibrous loam, one-fourth part of sphagnum-moss, and two-fourths of good lumpy peat, with a liberal sprinkling of coarse silver-sand and

small crocks added. Should any dry coddling be at hand, a very little dusted into the compost will prove beneficial. Water should be applied sparingly until new roots are visible in the compost, but absolute dryness must be avoided. Undisturbed plants will need a generous supply of water throughout the summer and autumn months, with an occasional weak dose of liquid farmyard manure. The old reeds which have flowered may in many instances be cut quite away to allow the young developing growths greater freedom, and to admit light and air into the centre of large specimens. To prevent thrips and red-spider, spray the under sides of the foliage once or twice a day whenever the weather is favourable, and occasionally spray them with a solution of some approved insecticide. If sponging be done, the young growths must be carefully handled, for if the terminal leaf be dislocated the growth will not flower.

Cattleya Bowringiana.—This useful autumn-flowering species is rapidly developing its growths, and great care is needed to prevent an accumulation of water in the sheathing-bracts. The plants should occupy a part of the Cattleya-house where most heat is obtainable, together with free ventilation, and a good light. Until a new series of roots appear the base should only be kept just moist; and if any potting is needed, it should be done immediately the new roots are seen. This *Cattleya*, and the many beautiful hybrids of which it is a parent, thrive exceedingly in a compost with which decaying Oak-leaves are incorporated. The receptacles should be furnished with drainage material to nearly half their depth, and the surface of the potting compost may be finished off with chopped sphagnum-moss, or peat and moss as in the ordinary way. Care must be taken to prevent the new material getting too wet. It may be kept in a suitable state for some time by judicious sprays and dampings amongst the pots, with a thorough watering now and again when the whole has become moderately dry. During the resting period few *Cattleyas* will keep in condition for so long a time without water as do the members of this group.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Meconopsis Wallichii flowers at this time, and requires an abundance of water, as the plants thrive in a compost of gritty loam and peat in a damp and shady position which is sheltered from strong winds.

Mertensia virginica and other varieties are also good plants for cultivation in sheltered corners in peaty soil.

Cornus mas elegantissima is an excellent plant for cultivation in large rockeries. Its creamy-white foliage tinged with red colour is improved by grafting it on to the green-leaved variety.

Herbaceous Border.—Cut away old flower stems of *Delphiniums*, *Inula Hookeri*, *Papaver pilosum*, &c. Afford a rich top-dressing to the plants to encourage them to make new growth that will flower later. *Dicentras*, *Eremuri*, *Paeonias*, *Veratrum*, &c. will be dying down, and if bare spaces occur let them be filled up with *Paris Daisies*, *Salvias*, &c., that have been grown on in pots for this purpose.

Verbenas.—Commence to propagate a stock of plants to be kept through the winter and supply cuttings next season. It is preferable to provide a good batch of stock plants, and thus have a liberal supply of cuttings on several occasions, than to be "nibbling" at a few stock plants for weeks. The aim of the propagator should be to get the cuttings rooted as soon as possible to prevent their being "drawn." Let a compost consisting of leaf-mould, fine loam, and sand be put into a frame and made firm, adding a layer of sand on the surface. Select fresh shoots as cuttings from the base of the plant. Cut just under the third joint, remove the two lower leaves, and insert the cuttings firmly. Afford water afterwards, and apply shade when necessary. If given careful treatment the cuttings will make roots before there is much top-growth. When the roots are about an inch long pot the little plants singly, or if a large quantity is required dibble them into pots or pans a little distance apart, using a compost of loam, well-

decayed manure from a Mushroom bed, and a sprinkling of sand. Afford slight shade on bright days until the plants are established, then ventilate freely and use no shade. Pinch the shoots occasionally, and do not let the plants flower, they will then be good specimens when they are put into their winter quarters at the end of September.

Propagating other Plants.—*Koniga variegata*, *K. maritima minima*, *Mesembryanthemum cordifolium* var. and other kinds, *Iresines*, &c., can be rooted in pans, boxes, &c., in a frame with a close atmosphere, but when they have rooted gradually inure them to the light. They will stand through the winter in the same pans, &c. *Lobelias*, *Heliotropes*, &c., that were potted some time since should not be allowed to flower.

Annuals and Biennials.—Where these are used for spring-bedding some ground should at once be prepared for sowing seeds of the favourite varieties. The beginning of August is a suitable date for sowing, or a little later will be satisfactory in warm districts. Sow the seeds thinly in drills and transplant the seedlings or thin them early so that the plants will become stout and hard before winter sets in.

Hydrangea Hortensis is a valuable plant for furnishing vases, tubs, &c., and can now be propagated by inserting the partially ripened points of shoots in 4-inch pots containing a sandy compost. Place them in a frame upon a mild hot-bed, shade them on sunny days until rooted, and gradually harden them off, taking care to get the plants thoroughly ripened before winter.

Sedum spectabile may be easily increased by division and by cuttings. The variegated form is very decorative.

Sedum pulchellum is a dwarf evergreen species well worthy of a good position.

Epilobium Fleischeri is a useful late summer-flowering plant for cultivation on a wall or rockery. It may be increased by seeds or by cuttings. *E. abyssinicum* is a good tall plant for the border.

THE APIARY.

By CULORIS.

"Robbing" and its Causes.—During the past few weeks I have had occasion to visit a number of cottagers and others who keep bees, and have been much struck by the careless manner in which pieces of comb, containing in some cases sealed honey, and in others only a small quantity of honey, are treated. Bees seem to take a great delight in obtaining honey in such an easy manner, because to secure in a natural manner a sufficient load to take home a bee must visit 80 to 120 flowers. To do this in an average season it must be absent from the hive from forty to fifty minutes. Can there be any wonder then, that when an opportunity arises of obtaining a load in a few minutes, that the insect takes full advantage of the easy mode and discards the legitimate methods? Having emptied the combs lying about the hives, the bees seem as though they lose their mental balance and become confirmed thieves, entering the hives of their weaker brethren. Those most likely to suffer are such as are queenless from some cause or other. These bees are possibly older, therefore weaker, and less able to defend their stores; also they seem to be indifferent to what the robbers are doing. The rogues push by the bees on guard and rush out, to be caught occasionally. Then a struggle ensues upon the alighting-board, and the robber and several of the defenders of the colony roll off the alighting-board to the ground, where the struggle continues until the thief either escapes or is killed. Later in the season robbing is caused by spilling syrup in the neighbourhood of the hives, and by placing on the feeders during the day, evening being the best time for this kind of work.

How to discover the Hive from which the Robbers come.—Flour the bees as they leave the hive or hives which are being robbed, and then notice where they enter.

How to stop it after it has commenced.—Unite all queenless stocks to nuclei, if they are weak from some other cause than queenlessness, then unite two or more weak colonies, and in both cases close the entrances so that only one bee can get in or out at a time.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

		Bank Holiday.
		Basingstoke Horticultural Society's Exhibition.
MONDAY,	AUG. 7	Dudley Horticultural Society's Exhibition.
		Seaham Harbour Horticultural Exhibition.
		Ramsey Horticultural Show (2 days).
TUESDAY,	AUG. 8	Flower Show in Abbey Park Leicester.
WEDNESDAY,	AUG. 9	Exmouth Horticultural Society's Show.
THURSDAY,	AUG. 10	Royal Botanic Society (Anniversary Meeting).

SALE FOR THE WEEK.

FRIDAY NEXT—

Importation of *Cattleyas gigas* and *aurea* received direct, also imported and Established Orchids from various sources, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30 o'clock.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—62.3°.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, Aug. 2 (6 P.M.): Max. 74°; Min. 54°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, Aug. 3 (10 A.M.): Bar., 27.7; Temp., 61°. Weather—Continuous rain.

PROVINCES.—Wednesday, Aug. 2 (6 P.M.): Max. 65°; Bournemouth; Min. 56°. N. of Ireland.

"Mutants" and Hybrids.

DR. T. MACDOUGAL, under the auspices of the Carnegie Institution at Washington, and with the assistance of Messrs. A. M. VAIL, G. H. SHULL, and J. K. SMALL, has published a paper on this subject which will be highly valued by those naturalists desirous of seeing in their own language the records of the evidence furnished by DE VRIES and others as to the existence and nature of the so-called "mutants." Instead of looking on the origination of species as a very gradual and a very slow process, DE VRIES, as we noted in a recent review of his lectures, shows that in some cases it occurs suddenly, without gradational or transitional forms, much in the same way as sports or bud-variations do. The absence of "missing links" is on this view a matter of no importance. Moreover, this phenomenon is stated to occur only at one particular period of the life of a species, and is not universal, but confined to certain forms.

The species may exist for years without any material change, and then all of a sudden the plant may enter upon a period of "mutation," new forms being developed in the manner already indicated. Why, how, and under what conditions this sudden change occurs is not explained. Still there seems to be no doubt of the facts, whatever be their correct interpretation. Their existence helps to explain the extraordinary degree of variation observable, say in our common Brambles and Hawkweeds, no less than in our Ferns. If these variations be proved to be constant and reproduced from seed or spore, it will become necessary to treat them as "species," and to give them names accordingly, for between permanent variations and species no line can be drawn.

Heretofore botanists have been content to frame their conceptions of "species" from comparative observations of the living plant in the field, or of herbarium specimens. Obviously, when observation can be supplemented by cultivation and practical experiment, a much closer approximation to the truth is likely to be gained. This experimental cultivation has been carried on by DE VRIES, and his experiments are now being repeated under other conditions by other observers. The first object of the American writers above-mentioned was to ascertain exactly what *E. Lamarckiana* really is, what is its history, whence did it come? From the statements here made it would seem that *E. Lamarckiana* is the same plant as that previously called *grandiflora* by PURSH in 1814, and by BARTON in 1821. In 1862 the plant was figured in the *Floral Magazine* by Rev. H. H. D'OMBRAIN, who states that it was introduced to our gardens by Messrs. CARTER, of Holborn. These gentlemen submitted flowers to Dr. LINDLEY, who is stated to have identified it as *E. Lamarckiana* (presumably of Seringe in DE CANDOLLE'S *Prodromus*, vol. iii.). In the *Index Kewensis* the plant so named is referred to *E. biennis* as a synonym. *E. grandiflora* of Solander in Aiton's *Hortus Kewensis* is similarly referred to *E. biennis*. So that according to usual practice *E. Lamarckiana* would be considered as synonymous with *E. grandiflora*, and as a variety of *E. biennis*.

The large-flowered form, though common in cultivation, was little known in a wild state. The interest of DE VRIES' experiments led to a diligent search in various parts of America, and at length the plant was found near Taensa on the Alabama river, a locality whence specimens were sent to FOTHERGILL by BARTRAM in 1773 or thereabouts, and by him submitted to SOLANDER.

The re-discovered plant was grown in the experimental plots in the New York Botanic Garden, together with other nearly allied forms and with artificially produced hybrids. "Mutants" also appeared among these plants. The paper before us is occupied with the record of the numerous observations and experiments made. The details are too numerous and too technical for us to do more than allude to them. The interesting fact for the gardener to note is the value of cultural evidence in determining the existence and limitation of species, and in estimating the possibilities of hybridisation.

THE SCOTTISH HORTICULTURAL ASSOCIATION.—Some fifty of the members had their annual trip on July 29, when the gardens of the Earl of HADDINGTON, K.T., Tynninghame, were visited. Mr. McHATTIE (President), Mr. LONEY (Secretary), MESSRS. TODD, FORTUNE, SCARLETT, KIDD, GRIEVE, WHYTOCK, MACFARLANE, SINCLAIR, and many other representative men in nursery, market gardening, florist, and private gardening, were present, and inspected with pleasure the fine timber, including a grand *Fraxinus Ornus*, with very large specimen *Garrya*, Strawberry-trees, *Nandina*, Hop-tree [*Ostrya*?], and many flowering shrubs not at all common. The Apple-covered walk and the original Tynninghame Muscat were other objects of interest, while an ancient Mulberry-tree bore testimony to the mildness of the climate. Roses were practically over, Carnations in pots being the chief feature among flowers, with the usual lines of Sweet Peas, quantities of bedding plants, and in numerous borders a large selection of the best hardy plants.

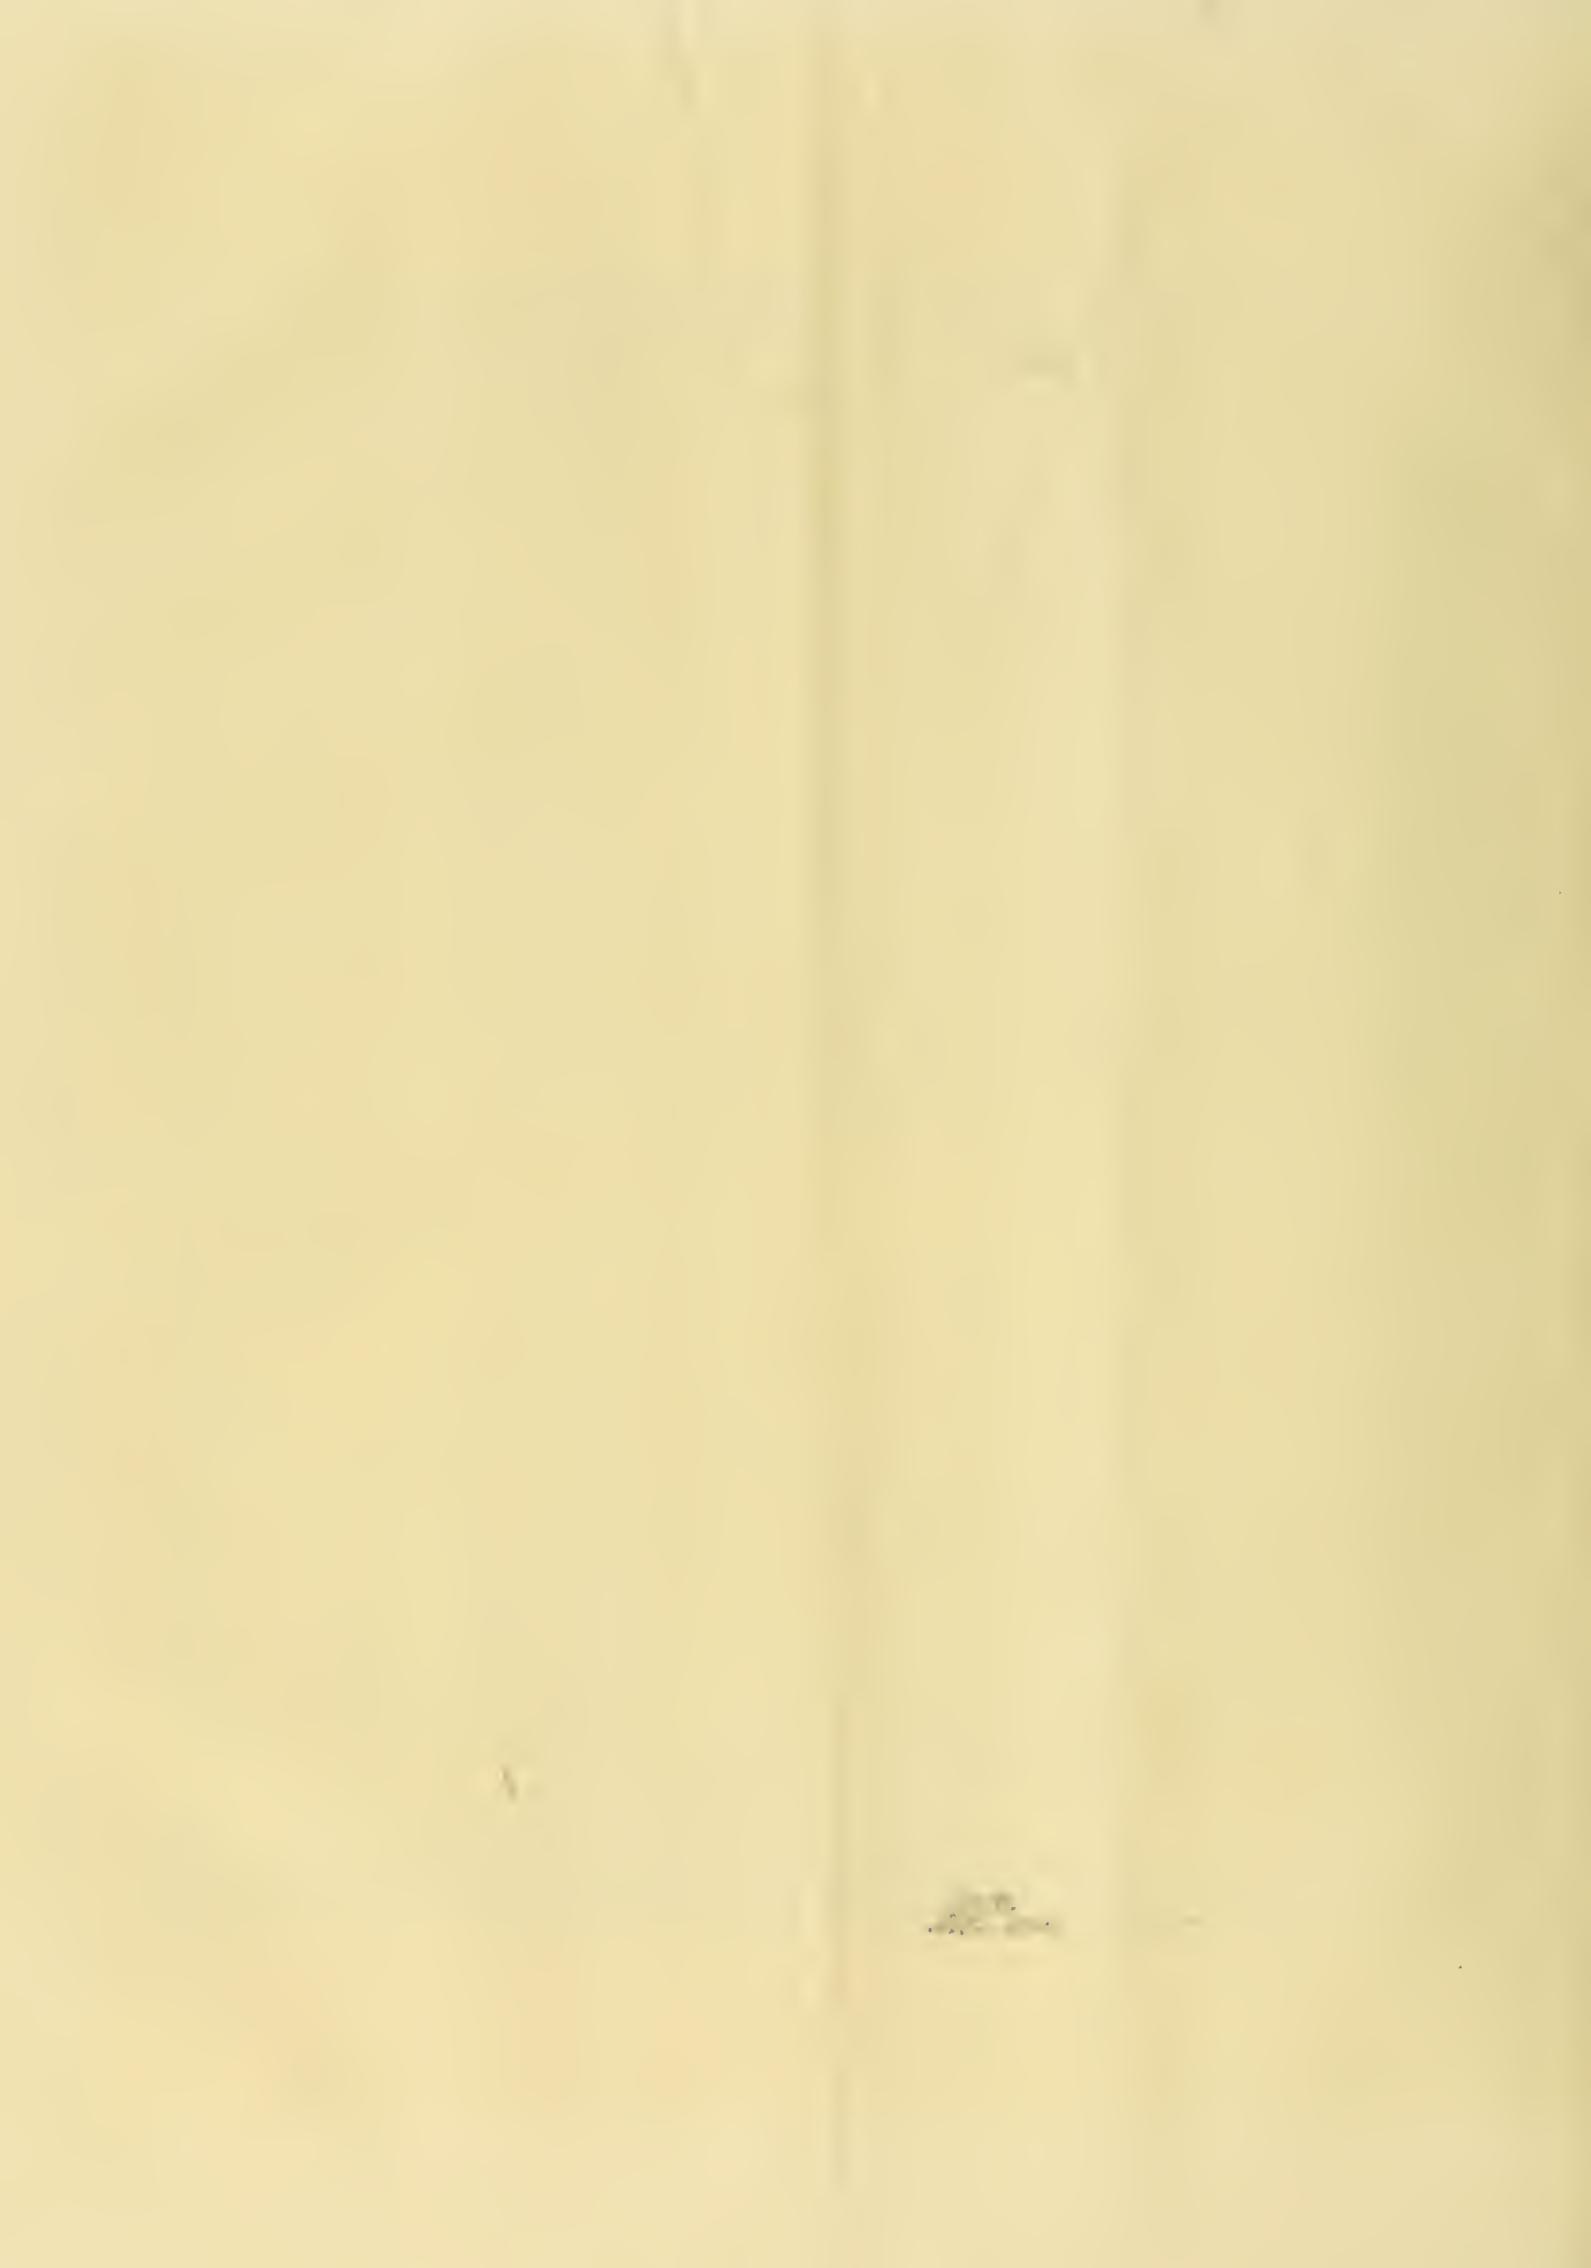

FOUR SHOWS OF COLONIAL FRUITS.—The Council of the Royal Horticultural Society, on the suggestion from the official representatives of several of our Colonies, have decided to hold four exhibitions of Colonial fruits and vegetable products, lasting two days each, on December 5 and 6, 1905, and March 22 and 23, June 6 and 7, and December 4 and 5, 1906. The object in fixing these dates is to suit as far as possible the season which is most likely to find the produce of Canada, British Columbia, and the West Indies; of India and the Cape; and of Australia, Tasmania, and New Zealand, in the greatest perfection in London. Opportunity is afforded for each Colony to make collective exhibits in addition to the exhibits of individual firms. The Agents General and other authorities are rendering every assistance, and we trust that both growers and shippers will do their best to send in exhibits worthy of our Colonies, and to show what can be produced for the home markets. No entrance fee or charge for space is made, and tabling is also provided free of expense. If desired any produce may be consigned direct to the Society, and it will be stored in the cellars at Vincent Square and staged by the Society's officials, but the Secretary cannot undertake to repack and return any exhibits. Medals and other prizes are offered by the Council in each of the many classes, which include Apples, Pears, Pineapples, Mangos, Grapes, Oranges, Limes, and other citrus fruits, Peaches and Nectarines, Plums, Melons, Tomatos, Nuts, Yams, and various tubers, and other Colonial fruits and vegetables. There are also classes for preserved fruits and vegetables, whether dried, bottled, tinned, jellied, or otherwise treated. The schedule and other particulars may now be had of the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.

HORTICULTURAL MEETINGS AT BRUSSELS.—

The Royal Linnean Society of Brussels (*Société Royale Linnéenne*) has made arrangements to hold horticultural meetings monthly in the State Botanic Garden of Brussels. Amateurs and nurserymen are cordially invited to attend these meetings and to promote their success by their assistance. These meetings are organised on the same general principles as those held in London and Ghent. The members of the Committee for 1905 are M. DE MIDDELEER (Chairman); Messrs. VERNIEUWE (Secretary of the Society), CLAES, DRAPS, MARCHANDISE, PEETERS, STEPMAN, DE WILDEMAN (Botanist), GOOSSENS (Artist), GENTIL (Secretary). The first meeting will be held on Sunday, August 20. Plants, flowers, fruit or vegetables must be arranged before 10 A.M. The jury will begin their work at 10 A.M. The public will be admitted at 11 A.M. The following

VIEW OF AN ORNAMENTAL POND IN THE GARDENS AT SOUTHWOOD, BICKLEY, KENT, THE RESIDENCE OF A. E. BEDDOW, ESQ.

Awards will be made as follows:—(1) Diploma of Honour for all novelties of exceptional merit shown for the first time at the Society's meeting. (2) Certificates and Honorable Mentions for novelties, good cultivation, or successful flowering. The Certificates will be awarded either by (1) the majority of the Committee; (2) unanimously; (3) by acclamation, or (4) with the "félicitations" of the jury. Amateurs and nurserymen unable to exhibit their produce themselves can send their plants, carriage paid, to M. L. GENTIL, Curator, Botanic Garden, Brussels. They will be sent back to their owner by the Committee. Meetings will be held in the autumn on Sept. 17, November 19, and December 17, 1905.

"THE BRITISH MOSS-FLORA."—The last part of this important work has now been published. It includes Family XXI.—Neckeraceæ II., and the supplement and index. We congratulate Dr. BRAITHWAITE on the successful conclusion of his long task, and on the patience and ability with which he has produced a standard work on these British Cryptogams. It need scarcely be added that the plates in the present part are as accurately and beautifully produced as those in former issues of the publication. MESSRS. LOVELL REEVE & Co. are the publishers.

CARDIFF GARDENERS' ASSOCIATION.—The ninth annual outing of the Association will take place (writes Mr. JNO. JULIAN, hon. secretary) on Monday, August 14, 1905, to the King's Acre Nurseries, Hereford, by the invitation of T. SETON, Esq., Managing Director. The train will leave the Great Western Station, Cardiff, at 8 A.M., returning from Hereford at 8.45 P.M. (saloons provided). It has also been arranged that after luncheon brakes will be in readiness to convey the party over a six-miles' drive to Holme Lacy (by kind permission of the Right Hon. the Earl of CHESTERFIELD), to view the historic and extensive pleasure grounds, &c.

"THE HORTICULTURAL DIRECTORY."—We are asked to state that the editor of the *Horticultural Directory*, 12, Mitre Court Chambers, Fleet Street, London, would esteem it a favour on the part of all head gardeners who have changed their addresses since October last, if they will send him a notice of their new address. Nurserymen, seedsmen, and florists who have changed either their address or title are likewise requested to notify the editor.

THE SILVER-LEAF DISEASE.—We had recently an opportunity of seeing the results of some inoculation experiments made by Professor PERCEVAL, of Reading. By a process very similar to budding, the Professor inserts a small fragment of mycelium of the fungus known as *Stereum*, or a portion of the leaf affected with the discolouration into the bark of Plum trees. After a time, varying according to the season at which the operation is performed and the place at which the insertion is made, the silvery appearance shows itself where before all was green. The appearance, as we showed long ago, is due to the detachment or raising of the epidermal layer from the subjacent tissue. The mysterious part of the business is that no fungus threads are to be found in the leaves, and so the conjecture is that the disturbance is caused by some ferment or "enzyme," secreted by the fungus, which creeps up the stem from the wound. It is evident that much remains to be done to clear up the matter, and it is equally obvious that Professor PERCEVAL is the man to do it. It is worthy of note that the disease is, so far as our experience goes, confined to the Drupaceous division of Rosaceæ, and that it occurs under glass as well as in the open-air. The only remedy we can suggest at present is to cut away the affected branches entirely and induce the tree to make new growth, in the hope (rather a forlorn one) that that new growth will remain healthy.

SWEET PEAS.—Messrs. J. K. KING & Sons, Coggeshall and Reading, write to say that their Sweet Peas were not exhibited at the Chelsea show in Bruce flower-holders, as was stated at the time, but in holders designed by one of their employés, and made on their own premises.

PHENOLOGICAL OBSERVATIONS FOR 1904.—Mr. EDWARD MAWLEY has recently published the results of phenological observations made in the various districts of Great Britain during 1904. The reports increase in value in proportion to their number. The desired result is to observe the connection between climatic variations and changes with the habits of plants. The exact effect of heat and cold, drought and moisture, and other climatal variations at different seasons upon agricultural and horticultural crops is not merely important in itself, but if observed for a sufficient length of time should be of assistance in forecasting the weather, and, in consequence, the probable effects that will ensue. The winter of 1903–04 was, on the whole, a cold one, with a paucity of sunshine. Seldom, according to Mr. MAWLEY, has there been a winter so unfavourable to the agriculturist. Flowers were checked in the gardens, and planting in many places was rendered impossible. The succeeding spring was colder and less sunny than usual, consequently, growth was delayed. No great extremes were, however, experienced, so that no lasting damage was done. The summer was generally sunny, and the hay crop good. A drought and cold nights in July and August interfered with all plants and garden crops, and summer-flowering plants were late. The autumn was generally favourable. On the whole the year may be considered as being of an average nature as regards the weather. These reports cannot be made very definite, as they are gathered over a wide area, but the general facts remain uncontested. Extremes of all kinds exercise corresponding effects on vegetation, though these results are often not evident for some considerable time. Mr. MAWLEY publishes useful tables showing the areas under observation and the plants noted.

POTATOS IN 1904.—According to the *Returns* of the Board of Agriculture for 1904, the total production of Potatoes has only three times previously been exceeded, the greatest crop on record—3,743,203 tons—having been returned in 1884. England and Scotland both had in 1904 a yield per acre largely above average, the former by 6 cwt., the latter by almost 30 cwt., while an average of over 7 tons per acre, as was secured in Scotland, has never previously been noted in any of the three divisions of Great Britain. Wales was not so fortunate, the 4.84 tons per acre there returned representing about 12 cwt. less than the mean. Lincolnshire, the chief Potato-growing county, had a deficit of one-third of a ton per acre. In Scotland, one county only, Dumbarton, fell slightly below the normal. Banff and Kinross had almost 3½ tons above the average, while Bute, Caithness, Fife, and Forfar were all more than 2 tons to the good. The largest yield recorded in any single county was 9.45 tons on the small area in Clackmannan, while Banff also secured over 9 tons to the acre.

A "COUNTRY IN TOWN" MOVEMENT.—A Conference to promote the projected exhibition next year of London-grown flowers, fruit, and vegetables was held in the "One-and-All" club-room of the Agricultural and Horticultural Association, Long Acre. There was a large attendance of representatives of Societies and Institutions and of friends of the movement from the Metropolitan districts, as well as from Manchester, Birmingham, &c. The Hon. H. A. STANHOPE presided. Mrs. BARNETT gave interesting details of the projected garden suburb at Hampstead, where houses with garden surroundings are proposed to be built to suit all

classes of people, bringing rich and poor into the relationship of neighbours. Mr. E. O. GREENING read a paper on a "Country in Town Movement," giving information of developments in the United States and at home. The following resolution was moved by Mr. T. HORSFALL, of Manchester, seconded by Mrs. T. CHAMBERLAIN, of the Women's Agricultural and Horticultural International Union, and unanimously carried:—

"That this Conference approves the proposal to organise for 1906 an exhibition of flowers, fruit, and vegetables, grown in London and its suburbs, having separate sections for congested areas and the nearer and outlying suburbs. That the exhibition should include models, plans, and pictures, demonstrating the practicability of garden suburbs, the utilisation of vacant town spaces, and the floral adornment of London and other great cities."

A second resolution was moved by Mr. FRED ROGERS, and seconded by Miss LATTER, of the Invicta (L.C.C.) Infant School Gardens:—

"That this Conference expresses its sympathy with the project for a Hampstead Garden Suburb, and its determination to assist as far as possible in the realisation of the object."

On the motion of Mr. T. WHITEHOUSE, of Birmingham, seconded by Mr. T. BUDGET MEAKIN, it was agreed to reappoint the Council, executive, and officials, who have carried the work to its present stage, giving them power to add to their number.

EFFECT OF MANURES ON FRUIT.—M. ORIVE, reporting at the Paris Horticultural Congress in May last upon a series of experiments made under the auspices of the "Commission des Engrais," organised five years ago by the Société Nationale d'Horticulture de France, mentioned several details of scientific importance. The most noticeable result of the trials is the proof that plant-foods containing phosphates and potash produced a fruit that kept more perfectly than did fruits borne on trees in trial-grounds that did not receive similar foods.

GERMAN DENDROLOGICAL SOCIETY.—Under the presidency of FRITZ, Count of Schwerin, a very attractive programme has been arranged for the fourteenth annual Congress of the German Dendrological Society (Deutsche Dendrologische Gesellschaft). The meetings are to be held at Constance, from August 7 to 11. Papers are to be read on interesting and rare Conifers, Bamboos, Magnolias, and Roses that are hardy in Germany; on the history of the plantation of the island of Mainau, and on the results of the Nomenclature Congress of Vienna. Excursions are planned to some of the most beautiful parks and gardens of the neighbourhood, to the Empress EUGÉNIE's Castle of Arenenberg, the island of Mainau, Bregenz, and Lindau. Several itineraries are suggested for the homeward route, according to the locality in which reside the visitors to the Congress.

THE ROYAL METEOROLOGICAL SOCIETY.—The Council of the Royal Meteorological Society are desirous of advancing the general knowledge of meteorology, and of promoting an intelligent public interest in the science. They think that these ends can be most readily attained by means of lectures delivered in connection with scientific societies and institutions in various parts of the country. The Council have now appointed a lecturer, who is prepared to deliver lectures on meteorological subjects, e.g., How to Observe the Weather; Weather Forecasting; Climate; Rain-fall; Thunderstorms; Meteorology in relation to Agriculture, Health, &c. The lectures will be illustrated by lantern-slides from the large collection in the possession of the Society. Societies and institutions wishing such lectures will be expected to pay a moderate fee, and to defray travelling expenses. The Council are willing to arrange for exhibiting at the gatherings of local scientific societies, institutions, or schools, a

collection of photographs, drawings, diagrams, and charts illustrating meteorological phenomena, and of various patterns of instruments used for meteorological observations. They would also, if desired, lend and fit up a complete climatological station for exhibition, showing the necessary instruments in position and ready for use. The cost of transit and the expenses of a member of the staff in fitting up and superintending the exhibit would be borne by the society or institution inviting the co-operation of the Royal Meteorological Society. The Council are further prepared to lend sets of lantern-slides illustrating meteorological phenomena and instruments at a charge of 1s. per dozen and cost of carriage (minimum amount 3s.). Further information can be obtained from the Assistant Secretary, Royal Meteorological Society, 70, Victoria Street, S.W. Messrs. FRANCIS CAMPBELL BAYARD and HUGH ROBERT MILL are the Secretaries.

IF I HAD BUT ONE PEAR, WHICH SHOULD IT BE?—M. BALLET answers this question in the *Bulletins d'Arboriculture* by selecting Durondeau as the most generally suitable Pear. We do not think this Pear would be rated so high in this country.

ROYAL BOTANIC SOCIETY.—At the annual meeting to be held August 10, Mr. J. S. RUBINSTEIN will propose resolutions (1) Advocating a revision of the old bye-laws so as to secure for the Fellows a real voice in nominating and electing the members of the Council and the right to move resolutions at Fellows' meetings; (2) Deprecating the proposal to increase the Fellows' subscriptions; (3) Advocating the adoption of a policy calculated to attract new Fellows, and secure a substantial income from the admission money paid by the public, and with this view recommending that musical promenades be given next season on every Monday, Wednesday, and Saturday, the days the Gardens are open to the public, and (4) Urging the appointment of a Committee of Fellows to confer with the Council as to the best methods of improving the condition of the Society.

GARDENERS' OUTING.—The members of the Bath Gardeners' Society, or to print the very cumbersome title, "Bath and District Gardeners' Self-help and Debating Society," had their first annual outing on July 27 to Messrs. SUTTON & SONS' nurseries, Reading. The Society is a new one, but already includes 180 members, and the party that journeyed to Reading numbered 130. A most enjoyable day was spent, and in addition to inspecting Messrs. SUTTON's trial-grounds, &c., a visit was made to the gardens belonging to the Reading University College.

PUBLICATIONS RECEIVED.—*Bulletin of the Department of Agriculture, Jamaica*, July. Contents: Sugar cane, Soils of Jamaica, Tobacco of Jamaica, Banana Suckers, Cassava Trials, Culture of Central American Rubber.—*Bulletin of Miscellaneous Information, Botanical Department, Trinidad*, July. Contents: Notes on Experimental Plots, a Double Cacao Pod, Introduction of Cacao from Venezuela, &c.—*The Queensland Agricultural Journal*, June. Contents: Potato-scab in parts of Australia and New Zealand, Contributions to the Flora of Queensland, by F. M. Bailey: Tropical Industries, Forestry, and Notes on Stock Farming.—*The Agricultural Journal of the Cape of Good Hope*, July. Leading features: The Agricultural Union of Cape Colony, Extra-tropical Forestry, Experiments with Measles, and United Vine and Fruit-growers' Congress.—*Proceedings of the Academy of Natural Sciences of Philadelphia*, Volume XVII., part I, January to March, 1905, includes some papers on Invertebrate Cretaceous Fossils, and other subjects connected with zoology.—From the New York Agricultural Experiment Station, Geneva, N.Y., we have received the following Bulletins: No. 252, January, *Sulphur Washes for Orchard Treatment*; No. 254, *Potato-spraying Experiments in 1904*; No. 255, Part I, *Plant-Food Constituents used by bearing Fruit-Trees*; and Part II, *Tabulated Analyses showing amounts of Plant-food Constituents in Fruits, Vegetables, &c.*; and No. 257, *Effect of certain Arsenites on Potato-foliage*.—*Agricultural Bulletin of the Straits and Federated Malay States*, Edited by H. N. Ridley. The contents are chiefly devoted to subjects connected with the Rubber industry.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE PEACH AS A STOCK FOR THE PLUM.—I have just read one of the latest books from amongst the many modern ones on South Africa. The author, referring to the Cape and sundry fruit farms formed within its great extent, says Plum trees are not found to answer in the matter of fruitfulness when grown in the ordinary way, but that they are successful and fruit well when worked upon Peach stocks. This, by comparison with our home practice, is reversing the order of things. Has any reader of the *Gardeners' Chronicle* had experience with the Plum worked or budded on to the Peach? It may be the Peach proves a dwarfing stock for the Plum, after the manner of the Quince for Pears and the Paradise or Duncin stocks for Apples. W. Earley.

TRILLIUM SEED (see p. 96).—Your correspondent, Mr. O. O. Wrigley, should soak the seeds of Trillium in soft water, and add to it a lump of camphor about the size of a large nut, afterwards sowing the seeds in well-drained shallow boxes of sandy peat made firm. Afford a good watering through a fine rose before sowing the seeds, which should be placed on the surface at 1 inch apart each way, covering them afterwards lightly with fine soil which has been passed through a $\frac{3}{8}$ -inch sieve, and place a sheet of glass over each box. Let the boxes be put in a cold frame and be shaded from bright sunshine. The seed will then germinate, provided it has been properly ripened. When seedlings appear the glass must be turned each morning to dispel moisture. R. B. Tilley, Roath, Cardiff.

—It may be well to state that not a few Liliaceous plants are slow to germinate even when perfectly good seeds are sown. It is so with certain species of Lilies, and is often the case with Anthericum. Indeed, perfectly good seed, fully ripe when sown, and practically sown as gathered from the opening capsules on the plant, have all laid dormant for two years, but subsequently appeared as thickly as spring Onions, which the seedlings somewhat resemble in the early stages. In more than one instance I should have discarded the seed-pans but for the knowledge I possessed as to the quality of the seed. In the case of the Trillium I should now strongly suspect that the bulk of the seed was mere chaff, and in future I would advise your correspondent to practise artificial pollination, if this has not been done, in the hope of securing a much greater percentage of fertile seeds. Not infrequently seeds sown as soon as ripe will remain dormant longer than seeds of the same parcel not sown for some months later—a very curious and interesting fact. Sometimes in the Lily tribe the seeds vegetate, and no leaf-growth appears till the second year. In other species, as *L. giganteum*, germination is quick in the case of good seeds, and growth long continued. In the Daffodil (*Amaryllidaceae*), the season above ground in the first year of the seedling is usually very short, and is mentioned here as a sort of proof that the few seedling Trilliums spoken of by Mr. Wrigley have merely gone to rest in the ordinary way. E. H. Jenkins, Hampton Hill.

MR. BERNARD COWAN.—Mr. Bernard Cowan has just completed twenty-five years of service as Superintendent of the Westoe and Harton Cemeteries, South Shields. One of the first things that he turned his attention to on his appointment, was the re-modelling of Westoe Cemetery, and its present condition shows how judiciously he went about the work in selecting trees and shrubs suitable for the soil and climate of the district. Eventually, when it became necessary to take in more ground, the Harton Cemetery was formed, and the duties of laying it out devolved upon Mr. Cowan. His ideas from the first were to allow the eyes to rest upon flowers, trees, and shrubs, rather than on tombstones, and in this he has been eminently successful; so much so that in walking along the spacious paths one is reminded more of a public park than of a cemetery, as only occasionally are glimpses of tombstones seen. Mr. Cowan is one of the most popular of Northern horticulturists. He took an active and foremost part in the formation of the South Shields Chrysanthemum

Society, and has discharged the duties of honorary secretary since 1882. For some time he held an appointment as horticultural lecturer under the Durham County Council, and he occasionally contributes to the Press. He is senior Vice-president of the Royal English Arboricultural Society, and frequently contributes papers at the Society's meetings. B.

NICOTIANA SANDERÆ.—I have read with interest the article, in your issue of July 22, by your generally accurate correspondent, "J. O'B.," but in the note on the above-named plant he has made a mistake by claiming for it the property of keeping open during sunshine. I have had the plant under my own observation planted in the open in the locality of Worthing, and can say without fear of contradiction that this variety presents as sorry a spectacle, while the sun shines on it, as does *N. affinis*. E. B.

EXHIBITING SWEET PEAS.—The incident of the Sweet Pea disqualification ought not to be let pass without attention being called to the unhappily too common practice of judges disqualifying for very slight reasons. There seems to have been no option permitted in the instances in question, though an easy way out of the difficulty would have been to quietly remove a spray from the vase with over-numbers and said nothing further about it. Only the other day at a good show at Dunfermline, in a class the first prize for which was ten guineas, one of the competitors deviated slightly from the schedule. The attention of an official was drawn to the matter, and he promptly said, "You have power to disqualify." It was so clearly the result of an oversight, however, that he was requested either to put the matter right himself or to find the exhibitor and get him to do so, which he did, thus meeting the requirements of the case without penalising a man for a slight slip. Several years ago Mr. Haldane, K.C., M.P., gave a special prize, to be competed for by working men at Haddington, for a collection of so many sorts of vegetables. The best collection was found to contain a dish too many—if I remember rightly, a brace of Cucumbers being laid on another dish. On being referred to, I said it was an instance of forgetfulness to remove the Cucumbers, which proved to be the case, but disqualification followed. In a little show I have to do with, not a year passes but some one or other transgresses in quantity, but we never disqualify; the extra is lifted out, if not before the judges go round, then when they discover the mistake. There are, of course, instances when it is impossible not to disqualify, as when a different variety from that asked for in the schedule (as happens sometimes with Apples and Pears) be staged; but that is different altogether from a case where, say, a dish of the correct variety is staged containing one more than the number, the obvious inference being that in comparing the fruits the exhibitor has forgotten to lift the worst. Reverting to the question of Sweet Peas, it is clear that much ignorance prevails as to what an exhibitor ought to strive for. At a recent show of what a competent authority has described as the best exhibition of Sweet Peas ever held in Scotland, it was quite curious to see the remarkable differences in many of the lots. A fresh and altogether fine lot was shown with stems that had been shortened, and in one class the majority was set up in the same way, the exhibitor seemingly ignoring the fact that length of stem increases the value of a spray. There was, too, the exhibitor who sought to lengthen the stems by setting up the flowers with portions of the haulm, a fair reason for disqualification surely. A few placed themselves out of the running by setting up a limited number of one or two sorts, but the great majority—although the judges were not called upon to count the flowers—clearly staged a fair number of each. The winning lots achieved victory by length and strength of stem, by equality in the size of the blooms, by clearness and depth of colours, and by the number of flowers on each spray, in one case three and four blooms being the usual number. The number of first-rate varieties now existing that produce three and four blooms on each spray should lead to a recognised rule in judging to pass over those with two and sometimes only one spray. R. P. Brotherston. [If a number is

SOCIETIES.

THE ROYAL HORTICULTURAL.

AUGUST 1.—The usual fortnightly meeting of the Committees was held on Tuesday last, in the Hall in Vincent Square, Westminster. There was not so large a display as usual, but there was sufficient to

make a good show, and the exhibits included many interesting novelties. That autumn is approaching was illustrated by the collections of Gladioli and Hollyhocks, and even by Cactus Dahlias; the last-named, however, did not appear to excite such attention as they will command later on.

The attendance of visitors was unusually small, and

given in the schedule it should be absolutely respected by exhibitors and judges, for in all competitions the conditions should be well defined and unalterable after publication. In such cases a special award should be recommended, and the committee might consider if the schedule could not be made less exacting in future. Ed.]

THE PEAR-MIDGE (see article and illustration in our issue for May 20, 1905, p. 315).—I am one of the unfortunate gardeners who has suffered from the depredations of this most destructive insect. I am also one of those who has faith. I do not think that the Pear is to be a fruit of the past in consequence of the appearance of this destructive pest, and my faith is considerably strengthened after reading Mr. Saunders's advice in your issue of the 15th ult., except that Mr. Saunders asks us to trench the soil under the trees. Of course I need scarcely tell Mr. Saunders that to trench soil about the roots of fruit-trees spells ruin. But I also syringe or spray the trees several times during the winter with a strong solution of Quassia-extract and sulphate of potassium. Another most valuable insecticide as well as a fungicide, is liquid ammonia and sulphate of copper. But to those who are contemplating its use for the first time let me say, Be careful; it is a dangerous mixture. The danger lies in its preparation, as the fumes given off as the ammonia is poured on to the sulphate of copper are most destructive to animal and vegetable life. The copper sulphate should be smashed to a fine powder, and placed in a glazed earthenware vessel of some sort, and the ammonia poured on it. First cover the vessel with a thick bag or canvas to prevent the fumes escaping. Lift one side of the canvas up only sufficiently to pour the liquid on to the copper; this should be done quickly, the canvas being promptly fastened down over the vessel to prevent any escape of the fumes. It should be made in the proportion of 3 lb. of copper sulphate to 3 quarts of liquid ammonia. This may be diluted to 2 gallons by mixing more water after it has cooled. As the mixture of these two chemicals generates great heat I never allow any assistant to prepare it. After it has become cold, place it in a stone jar and cork tightly. Use a wooden stopper; tin or iron vessels are of no use, as this strong acid would burn through them in a short time. One of the objects in its use on the trees is to kill all moss and other vegetation, which it will do if used at the rate of 2 or 3 oz. to the gallon of water and sprayed into the trees several times during the winter. I feel sure also that if the Quassia-extract is used freely during the winter and before the trees open their flowers, and again after the petals begin to fall it will have good results. But it should be employed several times in order that all loose bark and the surface-soil may become distasteful to the insects. Of course I gather every fruit that has fallen from the trees at once. T. A.

I quite agree with your correspondent, "T. A.," that it would be most undesirable to interfere with the roots of the trees if it were possible to avoid doing so, but in the case of a bad attack by this pest it might be of more importance to destroy the insect than to save the roots which are near the surface. It would have been better to have said, If the surface soil can be turned down so as to bury the chrysalides from 9 inches to 1 foot in depth without much injury to the roots. I may say that in a recent article by a very competent naturalist on this insect which I consulted before writing what I did, it is stated, "Finally, as far as my experience goes the most successful remedy is to trench deeply the ground beneath the trees in the winter." It would certainly be useful to trench the ground beyond the area occupied by the roots, as some of the chrysalides will in all probability be found there. As this insect passes the winter underground in the chrysalis state, spraying the trees during that season cannot lessen the risk of an attack the next spring by the Pear-midge, however beneficial it may be in other respects. Geo. S. Saunders. [Gardeners will probably find it best to take away as much of the surface-soil as can be removed without seriously injuring the roots of the trees, and to sterilise the soil by burning. Then apply a top-dressing of fresh material. Ed.]

COUNTESS
OF
RADNOR

GARDNER

J.G.S.

FIG. 39.—BORDER CARNATION HELEN, COUNTESS OF RADNOR: FLOWERS NATURAL SIZE; COLOUR RICH CRIMSON.

The variety was awarded an Award of Merit when shown by Mr. J. Douglas at a meeting of the Royal Horticultural Society on July 4. (See p. 24.)

this was the first occasion that the holiday season has influenced these meetings to such an extent.

The ORCHID COMMITTEE recommended awards, including one Award of Merit, and three Botanical Certificates.

The FLORAL COMMITTEE recommended ten Awards of Merit to plants of which short descriptions are given below.

The FRUIT AND VEGETABLE COMMITTEE made no award to a novelty, but among the medals bestowed was one of gold to Messrs. JAS. VEITCH & SONS for Gooseberries, and a "Hogg" Medal to Lord SALISBURY'S gardener, Mr. Norman, for a choice collection of fruit.

In the afternoon twenty-four new Fellows were elected, and Mr. C. T. DRUERY delivered a lecture on the subject of "Wild Sports of British Ferns."

Floral Committee.

Present: H. B. May, Esq. (in the Chair); and Messrs. W. Howe, Chas. T. Druery, J. T. Bennett-Poe, G. Reuthe, H. J. Jones, W. Bain, Chas. Dixon, Chas. Jeffries, Chas. E. Pearson, Chas. E. Shea, W. P. Thomson, W. Cuthbertson, E. H. Jenkins, W. J. James, J. W. Barr, J. F. McLeod, J. Jennings, C. R. Fielder, and R. Hooper Pearson.

Messrs. W. BULL & SONS, King's Road, Chelsea, exhibited a group of Caladiums, most of the varieties being different from those with which we are familiar. Some of the best were General, Tocantins, Japura, Adamastor, Icarus, and Guarapuava.

Messrs. W. PAUL & SON, Waltham Cross Nurseries, Herts, exhibited sprays of ornamental shrubs, some of which were in flower. A very fine Tamarix named "Odessana" was included, and others were Golden Oaks, Prunus Pissardi, Spiraea canadensis, Podocytisus caramanica, Pavia macrostachya, &c. Some good herbaceous Phloxes were shown, also several new Roses, including Gottfried Keller, a very free-flowering hybrid Briar, having characteristics of the Tea Rose: the flowers were semi-double, 4 or 5 inches across, of pale-rose colour with yellow centre. Another new Rose was the H. T. Earl of Warwick, a large flower of reddish-rose colour with shading of salmon (Silver Banksian Medal).

A collection of Selaginellas from Mr. H. B. MAY, Dysons Road Nursery, Upper Edmonton, represented a great deal of variety in these peculiarly interesting plants, of which there were fifty species and varieties exhibited. Mr. MAY had also a group of well-grown Bouvardias in flower of very choice varieties, and strongly-grown, profusely-flowered plants of Ixora Dixiana, an excellent variety (Silver Flora Medal).

Mr. L. R. RUSSELL exhibited a group of Codieums (Crotons), as small plants suitable for vases, but they had been recently repotted into larger pots than would be convenient for table decoration.

Flowers of tuberous-rooted Begonias were shown in glasses by Messrs. B. R. DAVIS & SONS, Yeovil Nurseries, Somersetshire. Double and single flowers of a number of varieties of a good strain were arranged in a very pretty manner.

Begonias of the tuberous-rooted section, and in which there were evident characteristics of B. Worthiana, were shown by Messrs. A. CHARLTON & SON, Eridge Road, Tunbridge Wells, but they were not so showy as the best of modern strains of Begonia.

Messrs. JOHN LAING & SONS, Forest Hill Nurseries, London, S.E., arranged a very pretty group of ornamental stove foliage plants on the floor of the hall. Among these plants was a new variety of Caladium of considerable beauty, and named Col. John Hay.

Messrs. JAS. VEITCH & SONS, Exotic Nurseries, King's Road, Chelsea, had a group in which some of their Chinese and other novelties were displayed, most of which have been fully described and some illustrated in these pages. Such are Senecio elvornum, Buddleia variabilis Veitchiana, whilst a new variety is described under "Awards." There were also fine flower-heads of Sambucus canadensis, and the lovely white flowers of Eucryphia pinnatifolia were well shown; also Inula racemosa, a new species, and Astilbe Davidii, &c. Messrs. VEITCH had also a group of tender plants on one of the tables. Among these were Exacum macranthum in capital condition, Begonia "Washington," a tuberous-rooted variety of dwarf habit, and having scarlet double flowers, such as would make a good "bedder." Several Kalanchoes were in flower, also other interesting plants, including Cyrtoceras multiflorum (reflexum), an Asclepiadaceous plant. An exhibit of cut flowers from "annuals" came from the same firm (Silver-gilt Flora Medal).

Messrs. WEBB & BRAND, Saffron Walden, Essex, reminded visitors that in their nurseries at least double-flowered Hollyhocks can still be cultivated with success. They exhibited a very large number of blooms in a somewhat stiff manner on boards, and behind these were arranged the stems cut from plants with the flowers upon them. The prettiest variety appeared to be one named Miss Lizzie King, of lemon-yellow colour (Silver Flora Medal).

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield, exhibited Buddleia variabilis Veitchiana, also a group of well-coloured Codieums (Crotons)

Messrs. H. CANNELL & SONS, Swanley, Kent, made a very large exhibit of hardy flowers, inclusive of perennial herbaceous species and annuals. Godetia Duchess of Albany, with large white flowers, was attractive; and there were numerous other varieties of Godetia. A very large-flowered strain of Salpiglossis, Browallia speciosa major, Antirrhinum, Centaureas, Clarkias, China Asters, Nemesias, and a red variety of the large-flowered Lavatera trimestris were shown among a very large number of other species. Messrs. CANNELL also showed semi-double and double varieties of zonal Pelargoniums, arranged

FIG. 40.—SPIRÆA AITCHISONI: FLOWERS PURE WHITE, LEAVES DARK GREEN, SHINING ABOVE.

An upper leaf and upper portion of inflorescence: natural size. A flower and a fruit enlarged. Recommended an Award of Merit at the Royal Horticultural Society's Meeting on Tuesday last. (See p. 115.)

and other stove foliage plants, and Asparagus medio-lobes myrtifolia (Silver Banksian Medal).

Mr. JAS. DOUGLAS, Edenside Nurseries, Bookham, again exhibited flowers of a number of varieties of border Carnations. One named Mrs. Shenton, of very large size and of salmon-buff colour, was prominent.

Carnations were shown well by W. A. WATTS, Esq., Bronwylla, St. Asaph. The varieties all belonged to the border section, and the flowers were cut with very long stems and exhibited in tall, cylindrical glasses. Several seedlings were shown, but these were not of superior merit (Silver Banksian Medal).

pretily in glass vases, and relieved with fronds of Adiantum Ferns. One of the most noteworthy of these was named Le Colosse, for though the flowers were only very slightly double, they were of large size and brilliant scarlet in colour. Ville de Poitiers is more carmine in colour, but very large in size. Of true pink varieties Mrs. Lawrence, Mme. Gabrielle de Rovira, and M. Anatole Roscleur were very good. Champ de Neige was the only pure white flower shown. (Silver Flora Medal).

Messrs. JOHN PEED & SONS, Roupell Park Nurseries, West Norwood, exhibited plants in pots and cut

flowers of Gloxinias, which, as arranged, produced a pretty effect.

Mr. AMOS PERRY, Winchmore Hill Nurseries, included amongst hardy flowers a number of herbaceous Phlox, *Asclepias tuberosa*, and other species, but the most interesting feature in the exhibit was the large collection of varieties of Nymphaeas, of which flowers were shown (Silver Flora Medal).

Mr. MAURICE PRICHARD, Christchurch Nurseries, Hants, exhibited a group of choice hardy flowers. Gladiolus of the Lemoine strain were very fine, also herbaceous Phlox, &c. (Silver Flora Medal).

Mr. E. POTTE, Cranbrook, also exhibited hardy flowers in which herbaceous Phloxes and Pentstemons, &c., formed the leading features.

The best exhibit of herbaceous Phlox was that from Messrs. GUNN & SONS, Olton, near Birmingham. The flowers were of superb varieties, had been well grown and were shown effectively.

PERCY WATERER, Esq., Fawkham, Kent, also made a capital exhibit of herbaceous Phloxes, staging smaller bunches of a large number of the best varieties (Silver Flora Medal).

Messrs. R. SMITH & Co., Worcester, staged some very nice hardy flowers, including those of several varieties of Nymphaea.

Messrs. KELWAY & SON, Langport Nurseries, Somersetshire, exhibited one of their magnificent displays of Gladioli. The flowers showed extraordinarily good cultivation, and the varieties were of the highest merit. One of them is mentioned under "Awards" (Silver-gilt Flora Medal).

Messrs. J. CHEAL & SONS, Crawley, exhibited Cactus and single-flowered Dahlias, which will doubtless be seen in better form at a later date.

Messrs. THOS. S. WARE, Ltd., Feltham, had a very showy exhibit of hardy flowers, amongst which the best of those now in season were included. Chrysanthemum maximum King Edward VII. and Lathyrus latifolius "White Pearl" were given special prominence in tall Bamboo stands (Silver Banksian Medal).

Mr. GEO. REUTHE, the Fox Hill Hardy Plant Nursery, Keston, had several good varieties of herbaceous Phlox, flowering sprays of Berberidopsis corallina, and a purple Liatris under the name of *L. montana*, described as coming from the mountains of California.

Messrs. BARR & SONS, King Street, Covent Garden, showed herbaceous Phloxes, Gladiolus, Scabiosa lutea gigantea, Nymphaea flowers, Liatris spicata (a capital border plant), and other hardy flowers in season.

Awards.

Spiraea Aitchisoni.—Very handsome flowering sprays of this exceedingly ornamental species were shown by Sir TREVOR LAWRENCE, Bart. (gr., Mr. Bain), and Mr. MAURICE PRICHARD. The species was named by Mr. Botting Hemsley, after the plant had flowered at Kew in 1889, and Mr. Nicholson, then Curator of the Royal Gardens, had drawn attention to the obvious differences in the plant from *S. Lindleyana*, of which *S. Aitchisoni* had been considered to be a variety. Mr. Hemsley first discovered the plant when assisting the late Dr. J. E. T. Aitchison to classify the dried specimens the Doctor made in the Kuram Valley, Afghanistan, in 1879. An illustration of the species and a full description by Mr. Hemsley was published in the *Gardeners' Chronicle*, October 6, 1900, p. 255. We now reproduce the illustration (fig. 40, p. 115), and for further particulars our readers may refer to the issue just mentioned (Award of Merit).

Berberis vulgaris foliis purpureis macrophylla [?].—This is the best purple-leaved variety of the common Berberis that we have seen, the leaves being of extra large size and of deep colour. Shown by Messrs. PAUL & SON, Cheshunt (Award of Merit). The Committee should not lend its sanction to such names; a name should be a name, not a description.

Buddleia variabilis magnifica.—Those who are familiar with the new *Buddleia* known as *B. variabilis Veitchiana* may easily imagine what *magnifica* is like, when we have described the flowers as being several shades deeper than *Veitchii*, therefore of rich reddish-lilac colour. This newer variety as shown is also more robust and has larger flowers. Shown by Messrs. JAS. VEITCH & SONS (Award of Merit).

Campanula "White Star".—A very pretty free-flowering variety of *C. carpatia* was shown under this name by Mr. M. PRICHARD, Christchurch. The flowers were 2½ inches across, white or of the very palest mauve colour, except a ring round the centre. The habit of the plant was very dwarf, and the flowers about 9 inches high (Award of Merit).

Carnation "Roy Morris".—This is a bright rosy-crimson self-coloured *Carnation* nearly 3 inches in diameter, and possessing a non-splitting calyx. Some of the petals are fringed, and the small petals in the centre of the flowers somewhat detract from their fine appearance. Shown by H. W. G. MORRIS, Chipping Norton (Award of Merit).

Centaurea. Messrs. JARMAN & CO., Chard, Somersetshire, exhibited flowers of an unusually fine strain of *Centaurea*. The flowers were 3 inches in diameter, of refined form, and in colour the shades of yellow and purple were exceedingly pretty, in addition to some which were white. An Award of Merit was awarded for the strain.

Gladiolus "Lady Inchiquin".—A very lovely variety of charming pink colour with a little orange-yellow shading on the lower segments. The flowers are of very large size. Shown by Messrs. KELWAY & SON (Award of Merit).

Hemerocallis "Dr. Regel".—A free flowering variety with unusually deep orange-coloured flowers. Shown by Mr. M. PRICHARD (Award of Merit).

Montbretia Promethens.—This is the largest variety of this popular bulbous plant that we have seen. The plants as shown were more than 3 feet high, and the inflorescence was very much branched and bore numerous flowers. Each flower measured 3½ inches across, and was of rich orange colour with markings of deep red near the centre. Shown by Major PETRE, Westwick House, Norwich (gr., Mr. Geo. Davidson) (Award of Merit).

Sambucus canadensis.—This is an old species of Elder, commonly grown in the variety with golden-coloured leaves, but is not so well known as it deserves to be. Its branched cymes of white flowers make a prodigious "head" of bloom, and the flowers have an agreeable perfume. The leaves are pinnate or sub-pinnate, and the plants are said to grow 6 feet in height or more. Shown by Sir TREVOR LAWRENCE, Bart., and Messrs. JAS. VEITCH & SONS (Award of Merit).

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, F. Wellesley, N. C. Cookson, J. Colman, G. F. Moore, H. T. Pitt, R. G. Thwaites, J. Douglas, T. W. Bond, W. H. Young, W. H. White, J. W. Odell, W. Boxall, H. A. Tracy, H. Little, H. J. Veitch, F. W. Ashton, and H. Ballantine.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged the only group, but one of great merit, for which a Silver gilt Flora Medal was awarded. A feature in the group consisted of some good hybrid *Odontoglossums*, raised by Messrs. CHARLESWORTH, and among which the several forms of *O. x Rolfea* exhibited great variety. Two plants named "Heaton variety" had clear white ground colour in the flowers and violet-purple markings; two others had a greenish ground colour and lighter markings, while a third form had the white and purple flowers suffused with rose. Other hybrid *Odontoglossums* were Harryano-triumphans, with bright yellow flowers richly marked with purple; *Othello*, and *crispo-Harryanum*. The hybrid *Cattleyas* comprised *C. x Caduceus* (*Schofieldiana* × *Gaskelliana*), *C. x Wavriniana* (*Schofieldiana* × *Warsewiczii*), both showy flowers; several good *C. x F. W. Wigau*, *C. x Vulcan*, *C. x Fabia*, *C. x Fernand Denis*, and *C. x Germania*, the best of which, var. *magnifica*, secured an Award of Merit. The best of the *Laelio-Cattleyas* was the richly-coloured *L.-C. x callistoglossa splendens*, and there were other interesting and pretty plants, &c.

Sir TREVOR LAWRENCE, Bart., Burford, Dorset (gr., Mr. W. H. White), showed a very handsome specimen of the elegant little *Platyclinis filiformis* with 109 of its pendulous racemes of yellow flowers (Cultural Commendation). Also *Epidendrum ochraceum*, the pretty little *Theodorea gomesioides* (*Gomesia Theodorea*), a very distinct, dwarf-growing *Orchid* with ascending spikes of ten to twenty flowers, each half-an-inch across, and of the true *Gomesia* shape, though differing in colour and in the arrangement of the inflorescence. Sepals and petals yellowish, with purplish-red markings at the base; lip whitish (described and figured in the *Flora Brasiliensis*, fasc. 128 (1905), col. 250, tab. 55). There were also shown a good pan of *Nephelaphyllum pulchrum* and two others (see Awards).

F. W. MOORE, Esq., Glasnevin, Dublin, sent *Colax triptera*, which is a pretty species with green sepals and petals, the latter having small blackish markings,

and white labellum with rose disc. Nearest to *C. Puydti*.

H. S. GOODSON, Esq., Fairlawn, Putney (gr., Mr. Day), sent *Cattleya Gaskelliana* "Mrs. Goodson." A delicate bluish-white variety with citron-yellow disc.

GURNEY WILSON, Esq., Haywards Heath, sent a large form of *Cattleya Harrisonae* with broadly-developed and crisped lip approaching *C. O'Brieniana*.

Messrs. HUGH LOW & Co, Enfield, showed a fine large-flowered *Odontoglossum Pescatorei*, the one flower on which had clusters of violet-purple spots on the lip and lower sepals; also *Laelia* × *Iona*, *Cattleya* × *Mary Gratrix*, and a singular little *Angraecum*.

Mr. OTTO BEYRODT, Marienfelde, Berlin, showed *Phalenopsis Rimestadtiana*.

Messrs. JAS. VEITCH & SONS, Chelsea, showed the fine *Cypripedium* × *Jas. H. Veitch* (*Curtisii* × *Stenei platytenium*), with petals as in *C. x Morgania*, but broader and more densely spotted.

J. FORSTER ALCOCK, Esq., Northchurch, sent *Cypripedium "Gloriana"*, a hybrid of unrecorded parentage, with finely-formed, cream-white flowers tinged and veined with purple.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), showed *Cypripedium* × *Miss M. Sillem* (*niveum* × *Godefroyae*), a charming flower, an improvement on *C. niveum*. Flowers pure white, uniformly dotted with purple except the margins and lower halves of the petals. Also *Laelio-Cattleya* × *Wellsiana magnifica*, for which he had previously secured an Award of Merit. Flowers bright rose with a dark rose-purple feather on the petals and a rich crimson labellum.

R. G. THWAITES, Esq., Streatham Hill (gr., Mr. Black), sent *Cattleya* × *Atalanta ignescens*, very brightly coloured and of good form.

W. A. BILNEY, Esq., Fir Grange, Weybridge (gr., Mr. Whitlock), showed *Cattleya* × *Hardyana* "Gwendolen," a variety which, while adhering closely to the disposition of the colouring in *C. Warsewiczii*, gave unmistakable evidence of *C. Dowiana aurea* in the perfume and also in the intensely dark claret-crimson of the front of the labellum.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. Davis), placed on the table a two-flowered inflorescence of the unsurpassed *Laelia* × *Edward VII.*, which gained the highest honours, and formed one of the coloured illustrations in our Coronation Number (June 21, 1902). The flower was slightly lighter than on its first flowering, white tinged with lilac, the immense white rose-fronted, fringed labellum being a grand-feature. With it was a fine inflorescence of a very fine *L.-C. callistoglossa*.

AWARD OF MERIT.

Cattleya × *Germania magnifica* (*granulosa Schofieldiana* × *Hardyana*), from Messrs. CHARLESWORTH & Co., Bradford.—One of the best forms of this favourite hybrid, the flowers being large and well-formed; cream-white beautifully tinged and veined with purple; lip veined ruby-red.

BOTANICAL CERTIFICATES.

Promeneva (Zygopetalum) Rollissoni, from Messrs. CHARLESWORTH & Co.—A pretty, old but rare and free-flowering species with whitish-yellow flowers, with a few purple markings on the petals and base of lip.

Dendrobium ciliatum arvense, from Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White).—A dwarf Indian species which in this variety has white flowers with a purple base to the singularly fringed lip.

Grobya galcuba, from Sir TREVOR LAWRENCE, Bart.—A pretty species with whitish flowers spotted with purple, each an inch across, and with the upper segments disposed like a helmet; lateral sepals deflexed, yellow at the base.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., Chairman; and Messrs. S. Mortimer, Alex. Dean, Geo. Kelf, H. Parr, H. Markham, F. Q. Lane, J. Willard, J. Melndoe, C. Foster, Owen Thomas, G. Wythes, A. H. Pearson, J. A. Pettigrew (Boston, U.S.A.), G. Norman, and J. Cheal.

A collection of excellent fruits was shown by Lord SALISBURY, Hatfield House, Hatfield, Herts (gr., Mr. Geo. Norman). There were forty good fruits of *Erluge Nectarine*, two dozen fruits of *Bellegarde Peach*, and an equal number of the variety *Barrington*, a dish of *Brown Turkey Figs*, half a dozen medium-sized fruits of "Hatfield" Melon, a dish of "Florence" Cherry, dishes of *Langley Beauty* and *Crown* Bob Gooseberries, and six good bunches of *Madresfield Court Grapes*, that perhaps were scarcely perfect in regard to finish (Hogg Medal).

Messrs. JAS. VEITCH & SONS were awarded a Gold Medal for a truly magnificent display of Gooseberries, of which there were fruits of 100 varieties, shown in round baskets. Behind these there were plants in pots, trained as cordons and in other shapes (see fig. 41), which had been lifted from the open ground. The crops on these young trees were quite astonishing, and all the berries were very fine. No new varieties were shown

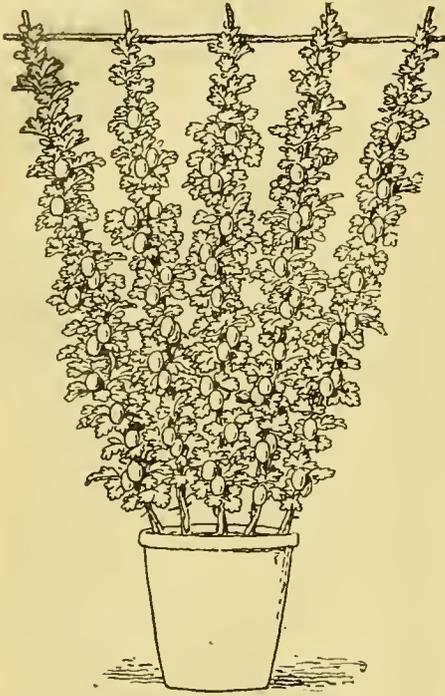

FIG. 41.—OBLIQUE CORDON GOOSEBERRY, such as was shown by Messrs. Jas. Veitch & Sons, Ltd., on Tuesday last.

than Langley Gage, Langley Beauty, and Golden Gem, all of which are of first-rate quality.

Messrs. DOBBIE & Co., Rothesay, N.B., exhibited a collection of about thirty-eight varieties of Potatoes. The tubers were mature, and good specimens, with clean, bright-looking skins. Such early varieties were included as Sharpe's Victor, Ashleaf, Beauty of Hebron, &c. (Silver Knightian Medal).

Messrs. RIVERS & SON, Sawbridgeworth, were awarded a Silver-gilt Banksian Medal for a group of pot trees of their new Peach, Peregrine, freely cropped with handsome fruits of rich flavour.

A seedling Melon named Lilley Brook was shown by H. O. LORD, Esq., Lilley Brook, Charlton Kings, Gloucestershire. Several very large fruits were staged, but they had little flavour, and the Committee suggested that smaller fruits should be shown on a future occasion, when the flavour may be better.

The Lecture.

WILD SPORTS OF BRITISH FERNS.

At the meeting of Tuesday, August 1, Mr. CHAS. T. DRUERY, V.M.H., F.L.S., gave a lecture, illustrated with lantern-slides, on "Wild Sports of British Ferns," his object being to demonstrate the absurdity of the general application by botanists, up to a comparatively recent date, of the term "garden varieties" to all abnormal types, regardless of the fact that the bulk of these types, in the case at any rate of British Ferns, were absolutely wild sports, entirely independent of garden cultivation. His aim was also to show that cultivation is by no means the main factor, if indeed it be a factor at all, in inducing sports of this distinct class, since all the types have originated spontaneously as wild plants, and all that the cultivator has been able to do has been to emphasise these types by selection from the seedlings if they vary, as they frequently do. The peculiar richness of the British Isles in wild Fern sports he evidenced by citing the latest list, which catalogues about 1,200 distinct forms as found wild among our comparatively few species, some forty in all, many of which vary but little and some not at all. He also combated the theory that sudden and wide varia-

tion of this kind was in any way due to changed conditions of environment, since they are mostly found on hill and mountain-sides, in glens and similar places, where the same conditions have prevailed from time immemorial, while they are furthermore generally intermingled, both as regards roots and fronds, with perfectly normal plants, not modified in the least. Mr. Druery then alluded to the fact that many most interesting discoveries had lately been made, including one by Professor Farmer, that certain abnormal reproductive Fern-cells were closely akin in their mode of development to those of cancerous growths in man, a fact which may afford a clue to the true nature of that dreadful disease. The first slide shown represented, in the form of a diagram, the various life-cycles of Ferns as depicted by Professor F. O. Bower, the normal roundabout process of reproduction through the spore being short-circuited, as it were, in apparently all possible ways; whilst the subsequent discovery of Dr. Lang that the Fern prothallus may bear spores, adds another of Nature's short cuts. Some forty forms of Ferns, representing ten species, were then shown on the screen, depicting first a number of wild sports, which were described seriatim, followed by a few of the beautiful results of selective cultivation, and concluding with a view of the lecturer's fernery, in which a number of the *élite* were grown under glass with charming effect.

The fact that these wild sports transmit their peculiarities as a rule to their progeny by spores was also adduced as strengthening Professor Hugo de Vries' theory of "mutation," by which he claims that such sports in plants generally have probably played an important *role* in the evolution of species.

CARDIFF AND COUNTY HORTICULTURAL.

JULY 26, 27.—The seventeenth annual show held by this Society took place on the above dates in the Sophia Gardens, Cardiff. Last year's show was a record one for entries, but there were still more this year. The stereotyped expression one hears so often at such times about the exhibition "being the best ever held here" was upon everybody's lips, and was probably more exact in its application than is usually the case, for apart from the large number of entries, the general excellence of the exhibits was of a very high order. The outstanding features of the show were the groups of plants arranged for effect, together with Roses, Sweet Peas, and herbaceous plants. Stove and greenhouse plants generally have never been of late years much in evidence at Cardiff, but they were less so at this time than previously. The fruit was very disappointing, and was quite the weakest point of the whole show.

A new departure, and one deserving of every encouragement, was taken by the Society this year by endeavouring to make the show of educational value to the children of the town. School-children to the number of 4,000 visited the exhibition on the morning of the second day, and after being conducted through the various tents, assembled around a bandstand to hear a lecture upon "What may be done in the Garden by the Young," delivered by Mr. W. Iggulden, of Frome. It was a matter of impossibility for all to hear the lecturer, but those who did must certainly have gathered some useful ideas regarding the management of their own small gardens.

PLANTS.

The competition in the classes for groups was very keen, and so meritorious were the various arrangements of plants that the judges had some little difficulty in awarding the different prizes.

For a group of miscellaneous plants, arranged for effect in a space of 150 square feet, Messrs. J. CYPHER & SONS, Cheltenham, were placed 1st with a very tastefully arranged and well-balanced lot of plants. The centre plant used was a tall *Kentia Fosteriana*, rising considerably above the highest plants at each of the four corners. Among the flowering plants used to give colour and variety to it were *Lilium*, *Odontoglossum*, *Miltonia*, and *Chironia*; while among other foliage plants were several graceful *Bamboos*, *Palms*, and *Dracenas*. The 2nd prize was awarded to Messrs. PHELPS & Co., Cardiff. *Gloxinia*, *Odontoglossum*, and *Schizanthus* were the predominating flowering plants, the last-named plant, associated as it was with *Odontoglossum*, appeared exceedingly like an *Orchidaceous* flower in general outline, and might easily have been mistaken for one. Lady HILL, Cardiff, was placed 3rd in this competition; and Col. WALLIS, Newport, was awarded an extra prize in the same class.

Mrs. EVAN LEWIS, Llandaff, carried off the 1st prize for a group of miscellaneous plants arranged for effect in a space of 50 square feet. *Humeas*, *Nicotiana Sandera*, and *Campanula pyramidalis* were the prominent features of this collection. The 2nd prize

was awarded to W. N. LAWES, Esq., Trowbridge, *Nicotiana Sandera* (associated with variegated *Abutilons* and *Cocos Weddelliana*) again taking a prominent place in this group. C. WALDRON, Esq., was successful in securing the 1st place for a group 25 square feet in area, which owed its beauty principally to such hardy plants as *Coreopsis*, *Clarkias*, *Montbretias*, and *Lobelias*.

The MARQUIS OF BUTE (gt., Mr. H. Farmer) put up a very large, brightly-coloured group, consisting of *Crotons*, *Dracenas*, and other ornamental foliage plants, which added considerably to the appearance of the collections, but was not for competition.

Messrs. J. VEITCH & SONS, LTD., King's Road, Chelsea, also exhibited a collection of choice stove plants, among which were noted several varieties of the newer *Crotons*, *Dracena Goldieana*, *Nepenthes Masteriana* ×, *N. Tiveyi* ×, *Maranta Sanderiana*, and *Ixora Fraseri*. For this exhibit the firm was awarded a Gold Medal.

CUT FLOWERS.

Notwithstanding the lateness of the season, there was very great competition in the various Rose classes. As might be expected, the individual blooms set up in the boxes were not nearly so attractive as the collections of Rose blooms arranged for effect. In the former case many of the blooms could be seen with damaged outer petals or unshapely centres, none of which defects was noticeable when the Roses were bunched together.

For twelve distinct kinds of Roses, three blooms of each, Mr. J. CROSSLING, Penarth, took 1st place, the blooms of Victor Hugo, Fisher Holmes and Kaiserin A. Victoria being the brightest on the board. Messrs. S. TRESSEDER & SON, Cardiff, were placed 2nd, two of their best blooms being Frau Karl Druschki and J. S. Mill.

Mr. GEO. PRINCE, Longworth, was awarded 1st prize for twelve distinct varieties of Teas or Noisettes, three blooms of each. In this lot *Maréchal Niel*, E. V. Hermanos and *Comtesse de Nadaillac* were the best. The 2nd honour was taken by the KING'S ACRE NURSERIES, Ltd., who showed among other blooms very good specimens of *Medea*, *Catherine Mermet*, and *White Maman Cochet*.

In the class for twenty-four blooms of distinct varieties, Messrs. J. JEFFERIES won the 1st prize, the most noteworthy blooms being *Declair*, A. K. Williams, and *Maréchal Niel*. Messrs. S. TRESSEDER & SON were 2nd, showing excellent blooms of *Duke of Albany* and *Her Majesty*.

Mr. GEO. PRINCE took the premier place for twelve blooms of any one variety other than a Tea or Noisette; the Rose shown was *Bessie Brown*.

White Maman Cochet, exhibited by Mr. GEO. PRINCE, was the variety which took the 1st place in the class for twelve blooms of one variety of Tea.

Mr. J. CROSSLING was awarded the Royal Horticultural Society's Silver Medal for having the best exhibit in the foregoing classes.

In the competitions restricted to amateurs and gentlemen's gardeners, R. F. HORBS, Esq., Worcester, took the 1st prize for twelve blooms, distinct varieties; and CONWAY JONES, Esq., Gloucester, won the 1st prize for twelve Tea Roses.

A Silver Cup and a 1st prize were awarded to Mr. GEO. PRINCE for a collection of Roses arranged for effect in a space of 6 feet by 3 feet. This stand of Roses contained a magnificent lot of blooms, among which were noticed *Maman Cochet*, *Papillon*, *Mrs. Treseder*, *Prince de Balzana*, and *Dorothy Perkins*. Mr. J. MATTOCK was placed 2nd with a group very little inferior to the first, including among other varieties *Irish Glory*, *Souvenir de Catherine Guillot*, *Madame Pernet Ducher*, *Lady Roberts*, and *Dorothy Perkins*.

CARNATIONS and PICOTEES again added their quota this year to the beauty of the floral display. With a collection arranged for effect, occupying a space of 6 feet by 3 feet, Mr. W. TRESSEDER was able to carry off the 1st prize and a piece of Silver Plate, offered by a firm of local jewellers. Some of the best varieties shown were *Volunteer*, *Purity*, *Lord Roberts*, and *Mrs. Nicolson*.

A good display of SWEET PEAS was made in a tent almost exclusively set aside to this beautiful and popular annual. Mr. T. JONES, of Ruabon, was fortunate enough to be able to clear everything before him in the various Sweet Pea classes. His exhibits were uniformly good, and comprised such varieties as *Black Knight*, *Miss Willmott*, E. Lewis, *Lady Grizel Hamilton* and *Dorothy Eckford*.

A Gold Medal was awarded to Mr. H. ECKFORD for a collection (not for competition) of Sweet Peas. *Admiral Togo*, *Queen Alexandra*, and *Agnes Eckford* were among the novelties exhibited on this stand.

The groups of HARDY FLOWERS in the open classes were of such excellent quality that it was a matter for regret that the Committee had placed them in such an unsuitable position in the tent. Indeed, one collection was so shaded and pressed down by a large shrub outside the tent that it was almost impossible to appreciate its full value.

An interesting discussion arose among the judges when this class came under their review, and one of

the best exhibits came very near being disqualified on account of its having blooms of *Romneya Coulteri* included in it. The schedule stated that no flowers of any tree or shrubby plant was to be allowed in this class. It is an exceedingly delicate point to decide whether *Romneya Coulteri* comes within the category of shrubby plants or not, for although it figures in the *Key Hand-List of Trees and Shrubs*, it also takes its place among the plants enumerated in the *Key Hand-List of Herbaceous Plants*; while in Nicholson's Dictionary it is called an herbaceous plant. The consensus of opinion, however, was that *Romneya Coulteri* is a shrubby plant, but as its admission among herbaceous plants had never been previously questioned, it was agreed to let it pass for this time.

Messrs. H. & W. EVANS, Llanishen, were placed 1st with their collection of hardy flowers occupying a space of 15 by 3 feet. *Astilbes* (among them *A. Davidiana*) were much in evidence, as well as *Globe Flowers*, *Delphiniums*, *Rudbeckias*, *Verbascums*, and *Eryngiums*. Mr. W. TRESEDER staged a similar lot of lovely flowers, hardly inferior to the exhibit which gained the 1st prize, and was awarded the 2nd prize.

In the amateurs' and gentlemen's gardeners' divisions, S. ROBINSON, Esq., obtained a Silver Cup and 1st prize for twelve bunches of hardy flowers; and a Bronze Medal was awarded to J. COREY, Esq., Cardiff, for a similar collection.

FRUIT AND VEGETABLES.

The exhibits of Grapes were neither numerous nor good, being of quite second-rate quality.

Two pot Vines (*Black Hambro*) trained in the form of an arch were staged by the Marquis of BUTE, for which a Gold Medal was awarded by the Society.

One of the most frequent accusations made against flower shows is that quality is too frequently sacrificed to size and appearance upon the exhibition table. That there are exceptions to this rule was very evident at Cardiff, for one of the largest, cleanest and brightest-looking Melons in the show was placed 2nd to a small poorly-coloured and miserable-looking fruit. The judges in this instance apparently decided very appropriately by their sense of taste rather than by their sense of sight.

Bienheim Orange, shown by Lady MOREL, Penarth, took 1st place among the scarlet-fleshed varieties, and *Victory of Bristol*, shown by the Marquis of BUTE, was placed 2nd. Dr. LYNN THOMAS, Cardiff, was 1st with a green-fleshed variety, while the Marquis of BUTE with *The Duchess* was again 2nd.

Fine examples of hardy fruits were shown by the KING'S ACRE NURSERY COMPANY, LTD. Gooseberry bushes laden with ripe fruit, growing in pots, formed a rather novel portion of their exhibit. A Gold Medal was awarded.

Vegetables were moderately well represented, taking into consideration the extremely dry season just experienced. Lord ALDENHAM, of Elstree; Mrs. JENNER, Lord ABERDARE, and Mr. SHEWRING, of Llandaff, were the principal prize-winners in the classes for vegetables.

TRADE EXHIBITS.

In addition to the Gold Medals previously mentioned as awarded to a number of exhibits, the following firms were also the recipients of a similar mark of appreciation:—Messrs. SUTTON & SONS for a collection of Melons and Tomatoes; Messrs. BLACKMORE & LANGDON for Begonias in pots; and Messrs. J. JEFFERIES for a group of coniferous trees and shrubs.

For collections of herbaceous and perennial plants the following firms were awarded Silver Medals:—Messrs. PRICHARD, of Christchurch; ISAAC HOUSE & SONS, Westbury; and J. C. WHEELER & SONS, Gloucester. Messrs. J. WATERER & SONS, Bagshot, were also granted a Silver Medal for a collection of retarded Azaleas. W. W. P.

ROYAL BOTANIC.

JULY 28.—A meeting of the Fellows of the Royal Botanic Society was held on the above date in the Society's gardens at Regent's Park, Mr. C. Brinsley Marlay presiding. Mr. J. S. Rubinstein said he wished to propose that a committee of Fellows be appointed to consider the position and to confer with the Council as to the best methods of improving the present condition of the Society. The Chairman ruled that no Fellow had, under the present constitution of the Society, any power to propose such a resolution. The Fellows, however, might appoint a committee to make suggestions to the Council. Mr. Rubinstein urged that a conference such as he suggested would be beneficial to the Society. They were in debt to the extent of £28,000, and the only way to get out of their difficulties was for the Council to take the Fellows into their confidence. He maintained that the Fellows were averse from the raising of their annual subscription to three guineas. Mr. Pembroke S. Stephens said that he and the other members of the Council would welcome any practical suggestions from the Fellows, and he advised Mr. Rubinstein and his friends to request the Council to receive and fully consider any definite proposa-

for improving the attractions of the gardens and for increasing the revenue of the Society. That would be better than publishing mere criticisms in the public Press. Mr. Rubinstein said that for fifteen years he had made suggestions without avail, and any improvements that had been brought about had been through the influence of the Press. Mr. J. Coode Adams said that but for the ruling of the Chairman he would have seconded Mr. Rubinstein's proposal. The by-laws of the Society were archaic, and it was an anachronism—nay, monstrous—that the Society should be conducted as it was. The Council had attempted to burke discussion, and were out of touch with the Fellows. Mr. Stephens said that the Fellows had it in their power to make the Society the most democratic institution in London. The Chairman denied that the Society was in the desperate condition that had been asserted. The Society, in his opinion, was never in a more flourishing condition, and if the Fellows raised their subscriptions there would be no difficulty. Dr. Coode Adams promised to propose in the Council that a sub-committee be appointed to revise the by-laws, and Mr. W. H. Sands said he would support the proposal. Mr. Rubinstein then placed on the table a list of gentlemen who, he suggested, should confer with the Council. *The Times*.

HORTICULTURAL EXHIBITION AT BRUGES.

JULY 30—AUGUST 15.—The present year being the seventy-fifth anniversary of the Independence of Belgium, the Government voted large sums of money to each provincial capital in order that an exhibition of the most important industries of the respective provinces should be held. Horticulture being a special feature of Bruges, the capital of West Flanders, it was decided to hold a national horticultural exhibition, and to invite an international jury to judge the exhibits. Although only a comparatively short time elapsed between the decision being made to hold the show and the opening of the exhibition, the organising committee and the exhibitors are to be congratulated upon the result, for the exhibition was of a very comprehensive and inclusive character, and in the specialities of the neighbourhood unsurpassed. The King of Belgium, himself a devoted patron of horticulture, honoured the exhibition with his presence on Sunday afternoon, and declared it open to the public. The jury and others were invited to meet His Majesty.

On entering the park-like enclosure one was impressed with the good effect produced by the noble groups of Bay trees, the chief speciality of Bruges, where hundreds of thousands are grown for home use and exportation.

On either side of the chief walk there were towering pyramids from Messrs. SANDER & SONS, and in the distance the 50-year-old standards from Mr. VINCKE DUJARDIN. Beyond were large decorative groups of such plants as *Dracenas* of the australis type, hard-wooded plants, the less tender species of Palms, *Conifere*, *Bamboos*, &c. All these exhibits were attractive on account of their excellence, and notably an extra fine group of "Plantes d'Orangerie," such as *Polygala*, *Metrosideros*, *Neelines*, &c., put together by Messrs. SANDER & SONS.

In front of the main building were beds of large and bright tuberous-rooted Begonias of the "Lafayettes" and similar bedding forms, amongst which we were much impressed with one called B. "Indépendance."

Before entering the structure devoted to greenhouse subjects we looked back upon a view of great historical interest and beauty, the ancient town of Bruges, with its many towers. The façade of the exhibition building, although simply constructed of laths, suggested strength as well as beauty. We were impressed by the ample and noble proportions of this temporary structure, provided for a short-lived exhibition. It had plenty of light, ample space, and was cool and comfortable. The walls were artistically draped, and the floor consisted of soft yielding sand. The conditions afforded a pleasing contrast to our stuffy, dusty, canvas built show places at home. The majority of the exhibits were laid out in beds, with side and central stages for the Orchids, Begonias, Gloxinias, &c.

Immediately in front was a group of three separate exhibits of the graceful and charming *Phoenix Roebelini*; from the side we looked over the dwarf groups of *Aspidistras*, *Kentias*, &c., to the back of the hall, on to a wonderful bank of Palms of extraordinary size, quality, and variety. Messrs. SANDER & SONS took the lead in classes for large specimens, as well as in those for smaller commercial plants.

The SOCIÉTÉ "FLANDRIA," M. DUMORI DE MENTEN, also showed splendid groups and specimens. Among the latter we noticed a grand plant of *Encenphalartos Altensteinii*; this, together with the vividly golden-coloured *Pandanus Sanderi*, and *Kentia Fosteriana "Leopoldii,"* from Messrs. SANDER & SONS, made a magnificent feature at this side of the hall. There was a very fine group from the same firm, consisting of a collection of new and rare stove and greenhouse plants, conspicuous amongst them being *Croton F. K. Sander*, a golden-leaved form; *Cycas Micholitzii*,

Pandanus Wavriniana, *Iguanura Curtissii*, &c., *Nepenthes Masteriana*, *Anthurium crystallinum*, *Asparagus myriocladus*. Anthuriums of the *Scherzerianum* type were represented by very fine forms from DE BOSSCHÈRE, of Antwerp; *Dracenas* from DRAPS DOM, of Brussels; flowering Bromeliaceous plants from LÉON POELMANN, of Mont St. Amand; *Gloxinias* from VAN HOUTTE; a new *Dracena* hybrid from *D. cannaefolia*; and *D. lineata* from DE NOYETTE, of Ledeburg, named *intermedia*, which is likely to prove a useful decorative plant, were noteworthy features.

Messrs. SANDER's large double-flowering tuberous Begonias formed a bank of blooms equal to anything seen at our English shows.

The STATE SCHOOL OF HORTICULTURE, Ghent, had an instructive exhibit of plants showing special adaptations for climbing, protection, &c.

Conspicuously bright amongst the numerous Palms, &c., was a group of the new hybrid *Nicotianas* raised by Messrs. SANDER & SONS.

We now come to a feature of the show which appealed specially to the writer's sympathies, viz., the Orchids, of which there was a very large and comprehensive display. There were many classes for individual specimens, collections, and groups of the popular species, as well as several groups of choice things of a non-competitive character. A large £10 Gold Medal was awarded to M. Ch. VUYLSTEKE, of Loochristi-les-Gand, for choice hybrid *Odontoglossums*. Included were a very fine *O. Lawrenceanum*, handsome *O. ardentissimum*, *O. bellatum*, *O. Rolfeae*, a lovely flower named *O. exaltum*, having pale yellow segments, paler centrally, with a lip suggestive of *O. Harryano-crispum* origin; *O. amabile*, and *O. percutum*, in which the sepals and petals are white, spotted pale brown, like a good *O. crispum*, and having a broad, flat lip, white at the apex, a many-toothed crest, spotted disc, and delicately spotted margin.

Mr. LAMBEAU, of Brussels, secured a Gold Medal for a choice selection of *Cattleyas*, *Lælio-Cattleyas*, *Vandas*, *Miltonias*, &c., chief amongst which were plants of *C. x atalanta*, *C. x St. Gilles* (very fine), *C. gigas superba* (a noble form), *C. x Wavriniana*, *C. guttata*, *C. F. W. Wigan*, &c.; L.-C. Admiral Dewey, L.-C. Miss Measures, and others; *Miltonia vexillaria superba*, M. *Cogniauxii* with nineteen flowers, *Cypripedium Wiertzianum*, *C. A. de Lairesse*, *C. Frau Ida Brandt*, &c.

Lower in the scale of merit was placed Mr. DIE-DRICHS, who also exhibited good plants—*Lælio-Cattleya* Admiral Dewey, L.-C. F. W. Wigan and *eximia*, *Cattleya Parthenia* Prince of Wales, *C. Wavriniana*, *Lycaste Skinneri* alba, &c.

Messrs. SANDER & SONS' non-competitive group, which was bracketed with the last-mentioned exhibit, contained a fine selection of *Cattleya gigas*, *Cypripedium Curtissii*, *C. praestans*, *C. glaucophyllum*, *Miltonias*, *Odontoglossums*, and many other good and popular kinds.

Coming to the competitive classes, the first to claim our notice was the group set up by Messrs. SANDER & SONS, which by many who had seen their efforts on former occasions, at home and abroad, was declared to be the most charming group ever staged. The background and side-wings were outlined with noble Palms and Tree-Ferns, twining and rambling over which were numerous spikes of *Oacidium macranthum*. The body of the group was filled in with glowing *Cattleyas gigas*, *Mendeli*, *Mossia*, *C. Mossie albo-cerulea*, *C. M. Reineckiana excelsa*, a glorious form, with very broad segments and deeply coloured lip; and *C. Rex*, now very rare. Centrally were placed good plants of *Cypripedium A. de Lairesse*, *C. "Lord Derby,"* *C. Parishii* (seldom seen); *C. insigne Sandere*, flowering out of season, was admired, also a grand plant of *C. Rolfeae superbum*. *Miltonias* of the *vexillaria* section were well represented by grand forms, such as *M. v. The Bride* (a pure white form), *M. v. gigantea*, *M. v. Chelseense*, *M. x Bleuana*, &c. Gracefully disposed amongst the bulk were plants of *Oncidium pulvinatum*, *O. Carthaginense roseum*, *O. Gardnerianum*, *Vanda cœrulea*, *Phalenopsis Rimestadtiana* *Dendrobium*, *Phalenopsis*, &c. Rare things, such as *Acineta Humboldtii*, *Catasetum Bungeothii*, *Acropera Loddigesii*, *Lycaste leucantha*, and others were also noticed placed to advantage amongst the many showy kinds. At one end was staged a gigantic specimen plant of *Brassia verrucosa* carrying thirty spikes of its spidery blooms, which was specially selected as worthy of an extra award. Near at hand was a good plant of the white form of *Masdevallia Harryana*. Messrs. SANDER & SONS gained the 1st prize for the above group "par acclamation," and with congratulations of the jury on their excellent style of arrangement.

In the class for fifty exotic Orchids, M. VINCKE DUJARDIN, of Bruges, was placed 1st with a good selection of *Cattleyas gigas*, *Gaskelliana*, and *Mendeli*, *Cypripedium insigne Sandere*, *C. callosum Sandere*, *C. Charles Canham*, *Oncidium carthaginense*, *O. leucocheilum*, *O. divaricatum*, *O. Forbesii*, *Vanda cœrulea*, *Phalenopsis Rimestadtiana*, *Miltonia Bleuana*, and a fine *M. vexillaria* named "Proserpine," of the *radiata* section. The same exhibitor secured the 1st prize for twenty-five Orchids, in which a good plant of *Odontoglossum Uro-Skinneri* was conspicuous.

In the class for a collection of twenty-five Lælias and Cattleyas, Messrs. SANDER & SONS were the successful exhibitors. The selection contained very fine plants and varieties of L.-C. callistoglossa, L.-C. Britannia (L.-C. Canhamiana x C. gigas), L.-C. eximia, L. x Helen, Cattleya Rex, now very rare, C. Mossiae Reineckiana, C. x Atalanta, with a spike of about a score of flowers, and others of more or less merit. M. VINCKE DUJARDIN was a good 2nd, with grand plants of C. gigas, C. Gaskelliana, C. Mendeli, C. x Vulcan (a pretty white hybrid between C. Gaskelliana alba x intermedia), C. x Wavriniana, L. x Helen, L.-C. Martinetti, L.-C. Henry Greenwood, L.-C. callistoglossa, and other showy kinds.

In a class for Vandaceous subjects Mr. DE VINCKE DUJARDIN was the only group staged, making a very pleasing display, with numerous examples of Vanda suavis, V. cœrulea, V. teres, Phalenopsis Rimestadtiana, and a good form of P. violacea.

In the class for fifty Odontoglossums Messrs. SANDER & SONS were an easy 1st, with numerous forms of O. crispum, O. Pescatorci, O. luteo-purpureum, O. Wilkeanum, O. Uro-Skinneri, O. cristatellum, a grand open-lipped form of O. Harryanum, and a magnificent plant and variety of O. x Rolfeae. Mr. VINCKE DUJARDIN secured the 2nd prize with O. crispum, &c.

In a class for ten Lælias and Cattleyas Mr. VINCKE DUJARDIN was again the only exhibitor, and secured the 1st prize.

In the class for twenty-five Cypripediums Messrs. SANDER & SONS were the only exhibitors, and were unanimously awarded the 1st prize. Amongst the number the best were C. Sanderiano-Curtisii, C. Harrisianum Baron Schröder's var., C. barbato-Rothschildianum, C. Phebe, C. niveo-callosum, and a very distinct variety of C. bellatulum, with white segments delicately spotted with pale rose-lilac.

For a single specimen of Cypripedium, Messrs. SANDER & SONS were 1st with a large plant of C. Harrisianum, Baron Schröder's variety, bearing over fifty flowers.

In a class for a single specimen of a Phalenopsis M. VINCKE DUJARDIN was 1st with a magnificent example of P. Rimestadtiana, having two spikes carrying four dozen flowers; Messrs. SANDER being 2nd with a plant of the same variety.

Anæctochilus were also provided for, Messrs. SANDER securing a 1st prize for a nice pan of A. setaceus.

Great praise is due to the committee of management for the thorough and efficient manner in which the show was so successfully carried through, and for the cordial hospitality they extended to the jury, the English representatives of which were Mr. W. Watson, of Kew; Mr. Segar, of Messrs. Wills & Segar, South Kensington; Mr. Icton, of Putney; and Mr. W. H. Young, the writer of our weekly Orchid Calendar.

MIDLAND CARNATION AND PICOTEE.

AUGUST 2, 3.—The fifteenth annual exhibition of the Midland Carnation and Picotee Society was held in the hall of the Birmingham Botanical and Horticultural Society, at their beautiful gardens at Edgbaston, on Wednesday and Thursday, August 2 and 3. It is hardly possible to imagine a better place for an exhibition of this kind. As usual in Birmingham, the blooms staged were of very high quality; and a great feature of the show was the magnificent display of "undressed" flowers—i.e., they were shown as grown and with natural foliage, the classes for which are even more numerous at this exhibition than those for "dressed" flowers. The schedule therefore has attractions for the old florist, whose heart always delights in flowers when exhibited in their neat paper collars, and also for those who favour the more modern and more effective style of staging the beautiful Carnation. The arrangements of the show were admirably carried out by Mr. T. Humphreys, the Curator of the Botanical Gardens, who has recently accepted the office of Hon. Secretary to the Society.

Selfs.—In the class for twelve selfs, dissimilar, Mr. W. H. PARTON, Hollywood, led with a very fine stand, containing splendid specimens of W. H. Parton (a deep maroon premier self), Daffodil (a grand yellow), Etna (scarlet), and Ensign (blush-white). Mr. R. C. CARTWRIGHT, of King's Norton, was 2nd with good flowers, among which were Daffodil, W. H. Parton, and Bride-groom, the last a fine pink.

Yellow-ground Picotees were well shown, and the chief honours went to Mr. A. W. JONES, of Stechford, who had good specimens of Peri (premier heavy-edged yellow-ground Picotee), Coquette, and Mrs. Walter Heriot. He was closely followed by Mr. W. H. PARTON, whose stand contained fine flowers of Mrs. Walter Heriot, Pilgrim, and Mrs. Durant.

The "Fancies" made a bold display, Mr. R. C. CARTWRIGHT leading with a very level stand, prominent in which were Ivo Sebright (which won the premier for the best fancy in the show), Hameo, and Royal

George. Mr. PARTON was a close 2nd, showing good flowers of Voltaire, Merlin, and Hameo.

White-ground Picotees.—Mr. PARTON's stand of white-ground Picotees contained notable flowers, such as Mrs. Openshaw (premier heavy-edged white-ground Picotee), John Smith, Fortrose, and Lucy. Mr. CARTWRIGHT'S 2nd prize stand contained the premier light-edged Picotee "Evelyn Cartwright," a new variety, raised by himself, for which a First-class Certificate of the Society was awarded. It is a grand addition to this section.

In the class for twelve bizarres or flakes, Mr. PARTON again led with a beautifully bright lot of flowers, notable specimens being Master Fred (premier bizarre), Gordon Lewis (premier flake), Admiral Curzon, and J. D. Hextall. Mr. CARTWRIGHT again ran him a close 2nd.

UNDRESSED FLOWERS.

In the class for undressed flowers which were most attractively staged, the honours in the chief class, viz., that for twelve distinct varieties of selfs, yellow-ground Picotees, or fancies were divided between Messrs. CARTWRIGHT and PARTON, who were classed as equal 1sts. The exhibits consisted of grand flowers, magnificently put up.

The class for twelve undressed self flowers was hotly contested, Mr. CARTWRIGHT leading with capital specimens; and Mr. PARTON winning 2nd prize.

Mr. CARTWRIGHT won another 1st prize for twelve undressed "fancies" or yellow-grounds. Mr. JONES was a very good 2nd.

In the smaller classes for six blooms some very fine flowers was staged. The Rev. C. A. GOTTWALTZ, of Droitwich, was champion in this section, winning the Silver Medal given by the Birmingham Botanical and Horticultural Society.

The most successful exhibitor in the classes scheduled for small amateur growers who do not grow more than 300 plants was Mr. J. D. WILLIAMS, of Smethwick.

A magnificent bouquet of Carnations obtained a 1st prize for Messrs. FELTON & SONS, of Hanover Square, London; and the 1st prize for a spray of Carnations was obtained by Mrs. W. H. PARTON. A much contested class for buttonholes of Carnations was won by Mr. W. L. DEEDMAN, of Edgbaston.

THE CHAMPIONS.

Mr. W. H. PARTON won sixteen 1st, nineteen 2nd, four premier, and three special prizes, as well as the Silver Champion Medal offered by the Birmingham Botanical and Horticultural Society, for the greatest number of points in the largest classes, and a Silver Medal offered by the Midland Carnation and Picotee Society, for the greatest number of points in the classes for single blooms.

Mr. R. C. CARTWRIGHT, of King's Norton, was a close competitor, securing sixteen 1st, fourteen 2nd, and two premier prizes. He also received a First-class Certificate for a light red-edged Picotee named Miss Evelyn Cartwright, a refined flower of great substance, considered to be the finest acquisition to this section for some years; and a First-class Certificate for Carnation "Cassandra," a superb purple self flower.

HONORARY EXHIBITS.

Silver-gilt Medals were awarded to Messrs. GUNN & SONS, Olton, for a magnificent display of hardy herbaceous flowers, herbaceous Phloxes being especially good; also to Messrs. BAKERS, of Codsall and Wolverhampton, for an attractive display of Roses and hardy flowers; and to Messrs. HEWITT & Co., the well-known Solihull Nurserymen, for a grand display of foliage and flowering plants, &c.

Messrs. BICK BROS., of Olton, obtained the only large Silver Medal awarded, for a grand display of alpinas; and small Silver Medals were awarded to Mr. W. SYDENHAM, Tamworth, for hardy flowers; Mr. S. MORTIMER, Farnham, for a pretty display of Dahlias; Mr. A. F. DUTTON, for a group of tree Carnations, which were greatly admired; Mr. AMOS PERRY, of Winchmore Hill, near London, who had a nice display of Nymphæas; Mr. VINCENT SLADE, Taunton, who staged Zonal Pelargoniums; and Mr. J. H. WHITE, Worcester, for a capital lot of hardy flowers. P.

Obituary.

PROFESSOR ERRERA.—It is with great concern that we have to record the sudden death, on the 1st inst., at Uccle, of Dr. Leo Errera, the Professor of Botany in the University of Brussels. The loss of such a man is a serious calamity for Belgian botany.

MR. DEWAR.—We have only now learnt of the death, in New York, on May 7, of Mr. Dewar, formerly of the Royal Gardens, Kew, and latterly Curator of the Botanic Gardens, Glasgow.

TREES AND SHRUBS.

ESCALLONIA PULVERULENTA.

This Chilean Escallonia is very rarely met with in cultivation, as it is more tender than the majority of the species, and even in very sheltered positions is often damaged in severe weather. It is now in flower. Its terminal racemes are about 6 inches in length and 3 inches in circumference, and the small blossoms composing the spike are pure white. The leaves are oval in shape, from 3 to 4 inches in length, and 1½ inch in breadth. In a young state they are very viscous, but lose this character as they become older. In the gardens at Greenway, on the river Dart, there is a good specimen about 7 feet in height. S. W. Fit-herbert.

HERBACEOUS FLOWERING PLANTS.

HELIOPSIS SCABRA SUPERBA.

This Heliopsis is an improved form of H. scabra, the orange colour being two shades deeper even than that of the variety H. s. B. Ladhams, which is generally admitted to be a far superior plant to H. Pitcheri. To the late Rev. Wolley Dod we owe this improvement in a desirable genus of August-flowering perennials, which, although allied to Helianthus, open their blossoms freely a month earlier than that plant; they are useful for cutting, as the foliage can be utilised along with the flowers. E. M.

MARKETS.

COVENT GARDEN, August 2.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

REMARKS.—English and foreign Tomatoes are cheaper, consequently large quantities are arriving daily, owing to the warm weather. English and Guernsey Melons are coming in fine condition, but owing to foreign sup-

plies are lower in price. Valencia Melons are a little firmer in price. Peaches and Nectarines are plentiful, and good fruit only is in demand. English Apples are arriving in very satisfactory quantities, and prices are very fair. Trade is declining a little owing to holiday week being near at hand.

GOVENT GARDEN FLOWER MARKET.

THE market is now very quiet indeed. It is only open on Tuesdays, Thursdays, and Saturdays for the sale of pot plants; on other mornings it is open from 7 to 9 A.M. for the sale of cut flowers only. The trade is over for the season, and even on market mornings most of the stands remain empty. Yet there are still some good plants. The supply of Pelargoniums holds out well, but the prices for them vary much. Campanulas are very good and sell fairly well: C. isophylla alba is the favourite; C. pyramidalis (both white and blue) is fine from several growers. A few good Fuchsias are seen, but they are not over plentiful. Marguerites are getting scarce. Mignonette is now over for the season. Verbenas continue to be over plentiful. There are still good plants of Hydrangea paniculata, and H. Hortensia is not quite finished, but the plants are not very good. Some good Bonvardias are coming in, but these are not much wanted until September. Coreopsis is very pretty, and Rhodantha is good. Heliotrope is also abundant. Foliage plants are plentiful, and prices vary but little. A good many hardy Evergreens are now seen. Hardy and greenhouse climbers are procurable. Among the latter are good plants of Plumbago capensis.

CUT FLOWERS.

Several growers are now sending Chrysanthemums from the open ground, but most of those seen are small and of rather rough appearance. Asters are over-plentiful, the large quantities imported from France spoil the trade for English growers. The supply of Sweet Peas is now getting short, and many of those seen are very poor. Montbretia is very pretty. It is now difficult to get really good Roses, but there are large quantities of small blooms. Lunums continue to be plentiful, but they vary in quality very much, the prices for best are low. Not many Callas are seen. Gladiolus bronchleyensis is very good, but much cheaper. "The Bride" is plentiful, but most of those seen have weak stems and small flowers. The smell of Lavender pervading the whole market reminds us that autumn is approaching.

The firm of T. A. Dickson, which has been so long established in the Centre Row, has removed to Albert Gate, and Mr. P. H. Garcia is taking the premises in the Centre Row. A. H., Wednesday, August 2.

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Fruit: Apples, Lisbon, 6s. 9d. to 9s. per case; Grapes, Denia, 6s. 9d. to 10s. 6d. per barrel; Melons, Valencia, 9s. 6d. to 11s. 6d. per case; Lemons, Naples, 15s. to 22s. per box; Bananas, 5s. 6d. to 9s. 6d. per crate; Tomatoes, Valencia, 5s. 6d. to 9s. 6d. per case; Onions, Valencia, 3s. to 4s. per case.—Vegetables: Birkenhead prices were as follows:—Potatoes, new, 2d. and 3d. per 5 lb.; Peas, 10d. to 1s. 2d. per peck; Cucumbers, 2d. to 4d. each; Tomatoes, 2d. to 3d. per lb.; Gooseberries, 2d. to 3d. do.; Raspberries, 5d. do.; Currants, Red and White, 4d. do.; do. Black, 5d. to 8d. do.; Grapes, foreign, 6d. to 8d. do.; Cherries, 1d. to 2d. do.; Apples, 3d. to 6d. do.; Pears, 3d. to 4d. do.; Plums, 3d. to 6d. do.

EDINBURGH.—Grapes, English, 1s. 6d. per lb.; do. foreign, Denia, green, 8s. 6d. per barrel; do. black, 10s. 6d. to 12s. 6d.; Lemons, Palermo, 11s. to 23s. per box; Apples, Lisbon, 12s. 6d. per case; Nuts, Brazilian, 3s. to 3s. 6d. per bag; Cherries, English, 11s. to 12s. 6d. per half bushel; Bananas, 5s. 6d. to 10s. per bunch; Figs, 9s. per dozen; Walnuts, Italian, 6s. 3d. per stone; Tomatoes, Guernsey, 5s. 6d. to 6d. per lb.; Onions, Egyptian, 1s. per cwt.; do. Valencia 5s. 6d. to 6s. 6d. do.; Carrots, 4s. per dozen; Gooseberries, 3s. 9d. to 4s. 6d. per half bushel.

DUBLIN.—Cabbages, York, 6s. to 11s. per load; Cauliflowers, 2s. 6d. to 4s. per basket; Parsley, 4s. 6d. to 5s. per bag; Parsnips, 2s. 6d. per cwt.; Carrots, 10d. to 1s. 2d. per dozen; Turnips, white, 7d. to 10d. per bunch; Rhubarb, 1s. 6d. to 1s. 8d. per dozen; Thyme, 4d. to 5d. per bunch; Marrows, 1s. 6d. to 3s. per dozen; Cucumbers, 1s. 3d. to 2s. per dozen; Salad, 6d. to 10d.; do.; Young Onions (scallions), 2 1/2d. to 3 1/2d. per bunch; Potatoes, 4s. to 4s. 4d., best qualities, 4s. 6d. per cwt.

ENQUIRY.

THE FALLING OF LIMBS OF ELM IN SUMMER.—I am anxious to learn from readers of the *Gardeners' Chronicle* whether in any case a limb that is perfectly alive and sound has ever been known to fall. The danger of large Elms from the falling of limbs is well known, but according to my experience the limbs that fall are partially dead, though the wood may be sound so far as rot is concerned. The timber is simply dry and brittle, while a sufficiency of living wood remains for the supply of sap to foliage. The presence of this wood may often be indicated by dead twigs, but I am anxious to know whether a fallen limb has ever been found perfectly alive, when there would be no dead twigs or small branches? R. I. L.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending July 29, 1905.

THE WEATHER IN WEST HERTS.

The Seventh Warm Week in Succession.—The past week was not so warm as the three previous weeks. On the warmest day the temperature in the thermometer screen only rose to 75°, and on the coldest night the exposed thermometer fell to within 5° of the freezing point. On the other hand, on one day, July 31, the heat in the sun was very exceptional; in fact, only once before in July has the black bulb radiation thermometer registered so high a reading, viz., 143°. Owing to the last two nights having been cold for the time of year the ground is not now as warm as it has recently been, but is still 2° warmer at 2 feet deep, and 1° warmer at 1 foot deep, than is seasonable. Rain fell on two days, but to the total depth of only about 1/2 of an inch. On the former of these days the rain was falling during a short thunderstorm for four minutes at the mean rate of nearly 1 1/2 inch an hour. These rains, coming as they did after a fortnight of dry weather, did not affect the percolation-gauges. For nearly three weeks there has been no measurable percolation through the bare soil gauge, but every day a few drops still trickle through it during the twenty-four hours. The sun shone on an average for six and a half hours a day, which is rather more than the mean duration for the end of July. The wind was moderately high on two days, but calms prevailed during the rest of the week. The mean amount of moisture in the air at 3 P.M. was about 5 per cent. less than a seasonable quantity for that hour.

JULY.

Exceptionally Warm, Dry, Calm and Sunny.—This was with one exception (1900) the warmest July of which I have here any record. There were no cold days, and but three cold nights. The nights were, however, as a rule more exceptionally warm than the days. On the two warmest days the temperature in the thermometer screen rose to 81°, which is rather a low extreme maximum for July. On the coldest night the exposed thermometer fell to within 7° of the freezing point—rather a high extreme minimum for July. Several of the nights were singularly warm. In fact on one night the thermometer on the grass did not fall lower than 61°—making it the warmest night but one I have yet recorded here at any period of the year. This was the driest July for seven years. Rain fell on ten days, but to the total depth of only an inch, which is less than half the average quantity for July. More than half the total rainfall was deposited on one day early in the month during thunderstorms. There was no measurable percolation through the bare soil gauge after the 14th. The sun shone on an average for 7 1/2 hours a day—or for 1 1/2 hour a day longer than is usual in July. This was a calm month indeed, only once before in July have I recorded so low a mean velocity, and in no hour did the mean rate of movement exceed 13 miles—direction west. The mean amount of moisture in the air at 3 o'clock in the afternoon was 1 per cent. below a seasonable quantity. E. M., Berkhamsted, August 2, 1905.

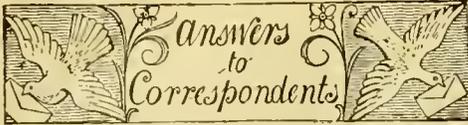

[For actual temperature and condition of barometer at time of going to Press, see p. 110.]

GARDENING APPOINTMENTS.

MR. THOMAS GREGORY, for the past three and a half years in the Gardens at Taplow Court, Sheffield, as Gardener to the Metropolitan Asylums Board at Caterham Asylum, Surrey.

MR. A. KETT, for the past thirteen years Gardener to J. CHRISTIE, Esq., Framingham Manor, as Gardener to F. PENN, Esq., Cawston Manor, Norwich.

MR. WALTER HOWARTH, Gardener for two and a half years at Eldersley Lauder, Red Hill, as Gardener to W. NOAKES, Esq., Selsdon Park, near Croydon.

AMMONIACAL SOLUTION OF COPPER CARBONATE: L. F. The proportions should be water, 16 gallons; carbonate of copper, 1 oz.; carbonate of ammonia, 5 oz. Mix the carbonate of copper and the carbonate of ammonia, and dissolve them in about a quart of hot water. When thoroughly dissolved add 16 gallons of cold water. You may syringe the trees with this liquid at the present time if you wish, provided there are no fruits to ripen. We advise that the root-pruning of the Pear-trees be done in October, rather than at an earlier date.

APPLE FIVE-CROWNED PIPPIN: R. E. B. This is another name for London Pippin, a very late-keeping variety, and if you ask for the variety under the latter name the nurseryman will probably be able to obtain it for you. Though described in Hogg's *Fruit Manual* as an excellent culinary Apple, and serviceable also for dessert, London Pippin is not commonly planted at the present time; and it is noteworthy that in the Apple-census we made last year by the help of our readers in all parts of the kingdom the variety was not mentioned at all.

BEDFORDSHIRE SEED COMPANY: J. G. H. The announcement was made as a matter of news only. We cannot undertake to forward applications for shares in this or similar undertakings nor to have anything to do with such transactions. Besides, had you read the paragraph carefully you would have seen that there is no initial public issue of shares.

BEGONIA: Norfolk. Tobacco-water is the remedy. You can dip the plants, or spray the liquid on the underside of the leaves, whichever method you find to be most convenient.

BEGONIAS: J. G. The plants seem to have rotted at the collar, probably from stagnant moisture, excess of heat, and defective ventilation.

CARNATIONS: T. E. H. A fungus, a species of Puccinia, has attacked the anthers of your plant. Burn the affected flowers.

CEANOETHUS: E. S. The shoots you send are smothered with a scale insect. Cut the plant right back in autumn and burn the prunings. That is your best chance.

CHRYSANTHEMUMS: W. G. M. and R. J. B. The leaves are affected with a fungus, probably the early stage of the rust fungus. Remove such leaves and burn them.

GRAPES: F. W. D. and W. B. The trouble is caused by the Grape-rot fungus, *Gloeosporium laticolor*. Mr. Massee recommends dredging with flowers-of-sulphur on the shoots and leaves, repeating at intervals of ten days if the disease continues to spread. A small quantity of quicklime should be mixed with the sulphur on the second application, and the quantity of lime should be increased on each successive application until the proportions of lime and sulphur are nearly equal, but always keeping just a little more sulphur than lime. It has been found of service thoroughly to wet the branches with a solution of sulphate of iron when the Vine is resting. Remove the diseased leaves and fruits and burn them without delay.

INSECTS: W. A., and Armitage Bros. The small beetles are those of *Phratora vitellinae*, a widespread enemy of the Willow and Poplar. The grubs or larvae are equally destructive to foliage; they measure about half an inch in length when full-grown, are of a pale dirty-yellow colour, with a black head and various black markings on the body. One of the best methods of reducing the numbers of this pest is to shake off the insects into a vessel containing a small quantity of paraffin oil. This plan, when steadily carried on, has met with marked success. Paris-green (Poison), at the rate of 1 ounce to 20 gallons of water, may be used with safety on certain foliage; but if used, it would be as well to experiment as to

desirable strength. As old bark-covered posts are favourable resorts for the beetles in winter, a few of these might be put down as traps.

JOURNEYMEN IN IRELAND: One in Doubt. There is no uniformity in the wages obtained by journeymen in Ireland any more than is the case in England, but generally they are, we believe, a trifle lower in Ireland. The matter of expenses incurred by going from one situation to take up another is one for arrangement between the interested parties. In ordinary circumstances the employer pays, if he has reason to think the candidate will continue in his employ for a reasonable period. The third-class fare from London to Dublin is 29s. 6d., or third-class railway ticket and saloon on steamer 32s. 6d. You will have to advertise for the situation you seek, or write to some of the Irish nurserymen. If you are a member of the British Gardeners' Association, perhaps they could help you.

LEAVES FOR THE MAKING OF LEAF-MOULD: Ardilea. The leaves would decay but slowly if packed in the pits as you describe, because so little air, and therefore little oxygen, would reach the bulk of them. But what purpose is it you expect to serve by adopting such a means of storing leaves? Unless you wish them to supply a little warmth in the house during their slow fermentation, we advise you to throw the leaves together in an out-of-the-way place in the open, or among high shrubs, and to turn them occasionally to expedite the process of decay. If you wish to put them into the pits, and would like them to decay quickly and thus afford heat, mix with the leaves a quantity of fresh droppings from the stable.

MELON: Anxious. You have the spot disease (*Cercospora melonis*) very badly. Burn the affected plants. See p. 96 of our last issue. The fault is not yours.

MUSHROOM CULTURE: A. T. B. A rain-resisting shed 60 feet long, having flow-and-return hot-water-pipes, should make an ideal place for Mushroom-culture at any season, and the dimensions of the proposed wooden trays would answer well, but they should not be placed over the hot-water-pipes, the drying influence of which would be unfavourable to the growth of Mushrooms, especially as these pipes have also to supply a stove temperature. Most sheds having earthen floors, we recommend you to form the beds on the floor, with only the side-boards to keep the material in place. The material most suitable for the making of Mushroom-beds is good stable-manure from well-fed horses. Collect the manure when it is possible to do so, and place it together, turning it over at intervals of a day or two to allow the accumulating heat and moisture to escape. In forming the beds, the manure having been so prepared for the purpose should be placed in layers from one end of the bed to the other, and made firm by being well trodden or rammed down. Do not have the manure in an excessively dry condition, but in an intermediate stage between wet and dry. When the temperature of the bed has declined to 80° preferably, or a few degrees lower rather than above this degree, the spawn may be inserted. Before doing this operation take every care to ascertain that the spawn is of superior quality and fresh. It is usually supplied in the form of bricks or cakes measuring 6 inches long by 4 inches wide, and the cakes are from 1 to 2 inches thick. Let each of these cakes be broken into six equal pieces, and insert the pieces at about 6 inches apart all over the bed, pressing them firmly just below the level of the material. Having made sure that the heat will not rise above the degree mentioned, the bed may be covered with rich maiden loam 2 inches deep, which should be applied in a moist condition, and pressed until firm. A moderately moist atmosphere should be maintained at a temperature of 60° to 65°. Darkness is not essential to the growth of Mushrooms, but a light covering of mats or canvas assists in keeping the soil damp. In a period varying from six to eight weeks it may be expected that Mushrooms will be in a condition for gathering.

NAMES OF FRUITS: Correspondent (no name). The Nectarine fruits were smashed in post owing to imperfect packing. The Asparagus appears to be *A. myriocladus*.—F. E. T. We are unable to name your fruit.

NAMES OF PLANTS: C. D. *Aconitum lycoctonum*.—F. S. 1, *Juniperus recurva*; 2, probably *Photinia serrulata*; 3, *Rhamnus Alaternus*; 4, *Phyllirea angustifolia*; 5, *Nyssa biflora*; 6, *Osmanthus ilicifolius*. Thank you for sending such good specimens. Would that other people were as considerate as you!—T. H. *Lilium chalcodonicum*.—W. B. 1, *Ruscus racemosus*; 2, *Scelopendrium vulgare*, Hart's-tongue Fern.—J. S. Orach, *Atriplex hortensis*, grown on the Continent for Spinach. It is not a *Celosia*, but belongs to a different Order.—J. B. B. The Fern No. 1 is an exotic *Lastrea*, probably *L. lepida*.

PEA: H. One of the varieties without inner skin to the pod, called by the French *Pois sans parchemin*.

PEAS: Old Subscriber. Thrips; try syringing with Quassia-water.

POTATOS: T. D. C. We have seen similar instances before. Obviously the conditions were not favourable, but how or why we do not know. After a prolonged rest they would probably do well next season. The eyes or sprouts have not developed.

PRIVET: A. S. We find no fungus, and without knowing the circumstances we cannot say what has killed your Privet on one side of the path only. Do the plants receive sufficient water?

ROSE: P. C. C. The Rose is too tender for outdoor cultivation in your locality. It is not affected with disease.

ROSE NIPHETOS: J. B. "What can we say about it?" A great deal more than we have space to afford. The Rose is prolific, the centre of the Rose having lengthened into a shoot bearing other Rose-buds, leaves, &c. A curious but by no means unique case.

SWEET PEAS: T. N. Union of two flower-spikes not uncommon, but why it happens we cannot tell.

TREATMENT OF LAND: F. W. C. Your idea of sowing Vetches on your land is a good one; if the Vetches fail sow field Mustard, because you evidently require an abundance of humus matter for the successful growth of vegetables on such a loose and stony soil. The Vetches can be sown in September, using the winter variety, putting in 3 bushels per acre. Before digging the ground sow broadcast a manurial mixture of 3 cwt. superphosphate, not less than 27 per cent. soluble phosphate, and 2 cwt. kainit per acre. In the after preparation of the land this will get well incorporated with the soil, and the seed can be drilled or sown broadcast immediately, and raked or harrowed in. The green crop may be dug into the soil in early spring, after which give a dressing of 2 cwt. bone-meal and 1½ cwt. sulphate of ammonia per acre; this will be better for your soil than nitrate of soda, as a general rule, although a little nitrate of soda, 1 ounce to a gallon of water, may be used with advantage for after-waterings of such succulent crops as Cabbage, Spinach, Lettuce, Turnips, &c. Animal liquid-manure, with which may be mixed a little soot, would be found of great value if applied during the growing season of the crops.

VINE BORDER: Ardilea. The reason advanced for making the border sufficiently large for a year or so, and adding fresh compost as more room for the roots becomes necessary, is a perfectly sound one. We advise you to adopt this method, which is widely practised among the best Vine cultivators.

YEW HEDGE: R. E. B. There is very little chance that the children will be poisoned.

RARE SHRUBS AND TREES AT MOUNT EDGCUMBE.

ABOUT a mile and a half from the mansion of Mount Edgcumbe is a spot called the "Terrace Garden," which is replete with interest to those whose especial bent lies in the direction of sub-tropical plants, for here may be seen many rare and tender shrubs and trees growing in vigorous health in the open air. This garden is about 250 feet above the sea-level, and is situated on a steep slope overlooking the western end of Plymouth Breakwater, and facing the English Channel. Below, by the water's edge, is a fort, invisible from the garden, which is well sheltered by Ilexes and other trees.

Among the shrubs and trees present were varieties of greenhouse Abutilons, grown as bushes, which at the end of July were bearing flowers of many colours; a good collection of Acacias, including *A. dealbata*, *A. floribunda* (retinoides), *A. melanoxydon*, *A. longifolia*, *A. ovata*, and *A. affinis*, which is held at Kew to be a variety of *A. dealbata*, but which is very distinct, as it flowers four months later, and its blossoms are of pale sulphur colour instead of golden-yellow. Some of these Acacias were fully 40 feet in height. *Araucaria Bidwilli*, 12 feet high, was remarkably healthy,

and *A. excelsa*, the Norfolk Island Pine, was 15 feet in height. The sweet-scented *Boronia megastigma* is doing well; a large specimen of *Callistemon salignus* was bearing its red bottle-brushes; *Candollea tetrandra* was spangled with bright yellow blooms and two great bushes of *Clethra arborea* were set with numberless budding flower-sprays. *Citrus trifoliata* (*Egle sepiaria*) and *Convolvulus Cneorum* were noted; and of the *Correas* the scarlet-flowered *C. cardinalis*, the handsomest of the family, 4 feet through, as well as *C. bicolor* and *C. virescens*. Two bushes of the yellow-flowered *Corokia buddleoides* were about 7 feet in height. *Diosma gracilis*, *Drimys Winteri* and *Edwardsia* (*Sophora*) *microphylla* were evidently happy, and of the pretty little *Eriostemons*, seldom seen in the open, *E. nerifolium*, *E. pulchellum*, and *E. linearifolium* were in perfect condition. Several *Eucalypti* were present, some of which were in flower. *Grevillea robusta* was about 5 feet through; *Helichrysum antennarium*, a shrubby tree about 10 feet in height, had just gone out of flower, as had *Illicium floridanum*; and of *Lagerstromia indica*, rare in gardens, there was a good specimen about 5 feet in height and as much in diameter. *Laurus Camphora* was 8 feet high, and the largest bush of *Lavatera assurgentifolia* was quite 7 feet in height and 5 feet through. This Mallow bears large handsome flowers of lavender-white tint, marked with deep blotches of maroon-purple in the interior. Several *Leptospermums* were of large size. *L. arachnoideum* was 12 feet in height and 14 feet through, *L. scoparium* somewhat taller, and *L. bullatum* equally fine.

A large Loquat (*Photinia japonica*) was observed, and I was informed that a specimen, which is since dead, bore fruit. This, as far as I know, is the only instance of the Loquat fruiting in the open in this country, though at Enys, in Cornwall, it often flowers. *Metrosideros robusta* was a small specimen; *Mitrasia coccinea*, hanging over a wall, was a gorgeous sight, being crowded with its scarlet, tubular blossoms; and the Australian *Myoporum laetum*, 15 feet in height, chiefly remarkable for its lanceolate leaves dotted with innumerable transparent spots, was bearing flowers and fruit. A great bush of *Myrtus uniflora* was blossoming well, and numerous self-sown seedlings were springing up around. A young Olive-tree was the picture of health; as were *Olea fragrans*, *Osteomeles anthyllidifolia* and *Polygala Dalmaisiana*. *Podocarpus andina* was 20 feet in height, and *Tricuspidaria dependens* and *Xanthoceras sorbifolia* were also represented.

Of plants grown against walls, *Acacia glaucescens* was 10 feet in height, *Brachysema Drummondii* was looking well, and *Bougainvillea glabra*, grown against a split Larch fence, 5 feet high, and particularly healthy. *Calceolaria Burbidgei*, 8 feet in height, was flowering, and was also grown in bush form, but *Cassia corymbosa* had not yet expanded its blossoms. *Cestrum* (*Habrothamnus*) *elegans* had made strong growth, and *Lasiandra* (*Pleroma*) *macrantha*, very vigorous, was 10 feet high. *Lonicera Hildebrandti* had not as yet flowered, but *Luculia gratissima* was said to expand blossoms in mild winters. *Mimulus* (*Diplacus*) *glutinosus* and its variety *coccineus* were in

full flower, as was *Pentstemon cordifolius*, which was bearing its red blossoms freely. *Plumbago capensis* was not in bloom, but *Trachelospermum jasminoides*, which covered the whole front of a large summer-house, was white with its fragrant flower-clusters. This plant has an extended period of bloom, for I have seen the same plant in flower in mid-October.

Of other plants *Agapanthus umbellatus* was blooming profusely, and *Alonsoa Warscewiczii* formed a brilliant spot of colour. The plant has passed the winter in the open unharmed. *Asparagus Sprengeri* was draping a wall with its feathery foliage, and *Echium densiflorum*, raised from seed sent from the Canary Isles, was in flower. On a steep, rocky slope about twenty plants of *Crassula coccinea* in full flower were associated with *Mesembryanthemums*, and presented a blaze of colour. Many *Crassulas* were in other stony banks, in company with *Opuntias* and *Lotus peliorhyncus*, which lives out through the winter. I was informed by Mr. Richards, the head gardener, that a large number of the best *Mesembryanthemums* had been received from Tresco Abbey Gardens, Isles of Scilly, where the finest collection in the British Isles is grown, so that in future years the terrace garden will present an even more brilliant spectacle. A fine specimen of *Cycas revoluta* has been in the open for several seasons, and large bushes of fancy *Pelargoniums* were flowering freely. *Iris* (*Morea*) *Robinsoniana* and *I. japonica* (*fimbriata*), were growing well, and I noticed several healthy plants of *Leonotis Leonurus*. *Primula obconica* that had been in the open through the entire winter was in flower, as was *Rehmannia angulata*, which appears likely to prove a hardy plant. *Clivia miniata* has been out for some seasons, and was evidently in good health. Besides the common Fan Palm (*Chamaerops*), *Phoenix canariensis* and *Cocos australis* are grown, as well as fine tree Ferns (*Dicksonia antarctica*) and giant *Camellias*.

The Cedars of Lebanon near the house were greatly injured by the memorable blizzard of March 11, 1891, which also levelled the finest of the Cork Oaks, but there are some about 50 feet in height still remaining. A Plane tree 80 feet in height, a Stone Pine, 50 feet, a Lucombe Oak, about 70 feet, and three enormous evergreen Oaks (*Quercus Ilex*), and a Holly, much shut in, which is apparently about 60 feet in height and over 7 feet in girth, are amongst the most noteworthy of the larger trees. *Embothrium coccineum* does well, as does *Abutilon vitifolium*, of which there are many specimens nearly 20 feet in height. Two trees of *Magnolia grandiflora*, whose drooping foliage swept the lawn, and which carried numerous expanded blossoms, are 20 feet high, as are examples of the Fan Palm, *Trachycarpus excelsus*.

In the Italian garden near the orangery a splendid collection of very well-grown and large Orange-trees in tub stands out through the summer. *S. W. Fitzherbert.*

HENRY ECKFORD TESTIMONIAL.—The contributions to this fund up to the evening of Saturday, August 5, amount to a little over £51, including 96½ shillings from the Florists' Exchange Fund. (W. ATLEE BURPEE, W. N. CRAIG, G. H. ROWDON, the Florists' Exchange.)

NEW OR NOTEWORTHY PLANTS.

PINUS PINCEANA.*

GORDON'S name for this Mexican species is nearly forgotten, owing probably to the defective type specimen at Kew, which consists of a single cone. Ghiesbreght's No. 34, however, to which

been identified and named. There are two sheets of leaves, and the cone is identical with the one at Kew. Palmer collected this Pine near Saltillo in the State of Coahuila. By some inadvertence the cone was associated with the leaves of another species, and to this combination Engelmann gave the name "latisquama." In the same locality, Carneros Pass, Mr. Pringle collected and distri-

At Carneros, P. Pinceana is a small tree not exceeding 20 feet, associated with P. cembroides Zucc., and now nearly exterminated. The few trees found were about two miles north-west of the station. George Russell Shaw, Boston, Mass.

FRUIT CULTIVATION IN SOUTH DEVON.

ABOUT the middle of June, in the finest weather of an English summer, I spent a few days along the South Devon coast, first amongst the beautiful seaside gardens and wooded slopes and heights of Torquay, the charms of which, as well as of those of its neighbours, Babbacombe and Paignton, are so well known that it is unnecessary to refer to them further than to say that the neighbouring country inland is amongst the most beautiful and characteristic of Devonshire scenery, and none, perhaps, more so than the village of Cockington, where the village smithy still exists, and the real "village blacksmith" still pursues his useful avocation amid all the surroundings which breathe the very air of an old-world place.

Within a stone's-throw of this quaint village and in the parish of Cockington itself, some 40 acres of land have been laid down under fruit culture, and constitute what is known as the South Devon Fruit Farm.

The term "farm" is fully borne out by the character of the grounds generally. The entrance is not marked by anything of an architectural significance, or of modern iron-work in the form of entrance gates, but a country cottage with an old-fashioned country garden, in which Roses assert their presence by their abundant blossoms filling the air with their sweet perfume, stands on one side of the entrance.

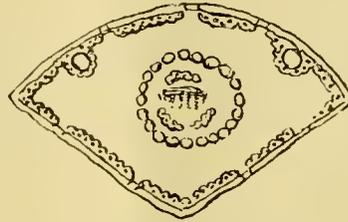

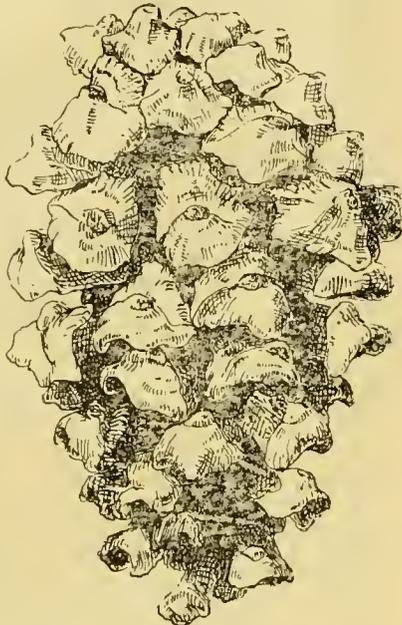

The other surroundings are those of the ordinary fruit and vegetable-garden cultures, except that everything is grown on an unusually large scale, the outdoor things being cultivated on a system of field culture, with the very best results in abundant crops and superior quality. It is, however, in the long and numerous ranges of glasshouses that the system of fruit-farming is best shown and fully realised. The houses are for the most part arranged in parallel lines. In one group each house measures 100 feet long, and is entirely occupied by Cucumbers and Tomatos. In another group the houses are double the length, and in these Grapes and Peaches are grown on a large scale.

In one Peach-house, 225 feet long by some 20 to 25 feet wide, the plants are trained on the espalier system across the house on strong iron and wire frames, the advantages of this being a perfect circulation of air between and through the plants, and the convenience with which the fruits can be gathered from either side.

I learned from Mr. Pender, the manager of this farm, to whose courtesy I am indebted for showing me round, that the whole of the produce, excepting the Peaches, is disposed of in the neighbourhood of Torquay, and that the Peaches, carefully packed in tray-like boxes which fit in one another so as to form convenient receptacles, are sent to the London market.

Some distance away from this rural spot, and located by the side of the line between Torre and Torquay, is situated another property belonging to the same company, known as the South Devon Rosery. As indicated by the name, Roses are here the chief objects of cultivation. They are to be seen in thousands, in every stage of growth and in every form and variety.

The closing in of the evening and the necessity for catching the train prevented my spending as much time as I should otherwise have liked to do in this garden of Roses. John R. Jackson.

FIG. 42.—PINUS PINCEANA, SHOWING FOLIAGE, CONES, LEAF-SECTION AND SEED.

Gordon refers in his original description, is in the Mexican collection at Paris, but has never

* *Pinus Pinceana*, Gordon.—Leaves in fascicles of three, the basal sheath deciduous, 3 to 4 inches long, with entire margins; the fibro-vascular bundle single and accompanied with stereome cells; the resin ducts marginal, dorsal, usually two in number, and enclosed by the hypoderm. Cone subterminal, stalked, pendent, symmetrical, and 2½ to 3½ inches long; the scales, when dry, concavo-convex, and of a deep red or orange-red colour; the seed wingless, large, and edible. The branchlets are ash-gray, slender and drooping.

Ghiesbreght, No. 34, Ravine of Meztitlan, 1844. Kar-

buted specimens under Engelmann's name. Karwinski found it, and his specimen, in the Zuccarini collection at Munich, bears the name "cembroides."

winski, *Zucc. Herb.*, No. 409, "in imperio Mexicano," 1844. Ehrenberg, near Cuernavaca, later date, vide Gordon. Edward Palmer, No. 1299, near Saltillo, 1880. C. G. Pringle, No. 2293, Carneros Pass, 1889. G. R. Shaw, same locality, 1904.—*Pinus Pinceana*, Gordon's *Pinetum*, 1858, p. 204, and 1880, p. 280. *Carrière, Con.*, 1887, p. 401. Hemsley, *Biol. Cent. Am.*, iii., 1883, p. 189. *Pinus latisquama*, Engelmann in *Gard. Chron.*, xviii., 1882, p. 713, fig. 125, and xx., 1893, p. 730, exclusive of the leaves.

ORCHID NOTES AND GLEANINGS.

ONCIDIUM LIMMINGHEI.

FLOWERS of this rare and pretty little Orchid are sent by Mr. Haddon, gr. to J. Neale, Esq., Lynwood, Penarth, where many interesting species find a congenial home. The plant, which in its one-leaved pseudo-bulbs much resembles a miniature *Oncidium Papilie*, bears its flowers on short filiform peduncles. The flowers, which are over an inch across, have the upper sepal and petals red-brown edged with yellow, the lower one light yellow barred with red-brown, the rounded basal auricles of the lip yellow spotted with red, and the emarginate blade bright yellow with a few red spots. It is a charming little plant, and it thrives best grown on a bare block or teak-wood raft in a moist corner of the Cattleya-house. The pseudo-bulbs and leaves press in a singular manner against the block on which it is grown.

SOBRALIA VIOLACEA ALBA.

Sobralia violacea is one of the commonest of South American *Sobralias* in a wild state, and collectors have recorded the fact that notwithstanding the rose-purple colour of the bulk of the plants, white varieties and light-coloured forms are plentiful. They are occasionally imported, and find their way into gardens under the name *S. virginalis*. A good white form has flowered with C. J. Lucas, Esq., Warnham Court, Hersham (gr., Mr. Duncan). The flowers are rather smaller than those of *S. macrantha*, and white, the disc of the lip, over which runs several prominent raised lines, being of orange colour. The margin of the lip is undulate, and the flower very attractive. Like all other *Sobralias* the individual flowers do not last long, but there is a good succession from the same stems. Given a liberal supply of rain-water and sufficient head-room in an intermediate-house (not necessarily an Orchid-house), *Sobralias* are very easy to grow.

CATTELEYA MOSSIE "GLOIRE DE LA FRANCE."

A two-flowered inflorescence of this charming *Cattleya* of the *C. Mossie Reineckiana* type, and which is a French production, is sent by Francis Wellesley, Esq., Westfield, Woking (gr., Mr. Hopkins), shows it to be one of the very finest of its class. The flowers, which are of good form and substance, are over 6 inches across, the petals pure white with a rich orange-coloured band from the base of the lip and extending into the side lobes. The front of the lip is veined and spotted with bright purple. Distinguishing features are its clear whiteness, the bright tints of the orange and purple colours of the lip, the decided manner in which those colours are displayed, and the broad, clear white, frilled margin of the lip. *J. O'B.*

SYRINGA VILLOSA

VAR. PUBESCENS.*

This is a species native to Northern China, and, judging from the remarks of various authors, is subject to considerable variation. Our illustration (fig. 43) was drawn by Mr. Worthington Smith from a specimen exhibited in the spring of the present year at the Royal Horticultural Society by Messrs. Paul & Son, of Cheshunt. Professor Sargent, in *Garden and Forest*, vol. i., 1888, p. 521, describes *S. pubescens* as one of the most distinct and most floriferous of all the Lilacs, and literally covered in June with its short panicles of small, long-tubed flowers, which are pale rose coloured, and most deli-

ciously fragrant. It is a shrub 3 to 5 feet in height, perfectly hardy, and one of the most attractive and beautiful of new introductions to our shrubberies. In the same publication, ii. (1889), 309 (ex Bretschneider), it is spoken of as an ornamental plant of the first class, which has the merit of flowering late long after other Lilacs; and again in iii. (1890), p. 322, it is

with smaller flowers than those of *S. villosa*. The specimen exhibited scarcely justified these eulogies, whence we experience some doubt as to whether Messrs. Paul's plant is specifically the same as that alluded to by Professor Sargent. Bretschneider (*History of European Botanical Discoveries in China* (1898), p. 1057, is of opinion that *S. pubescens* is specifically distinct from

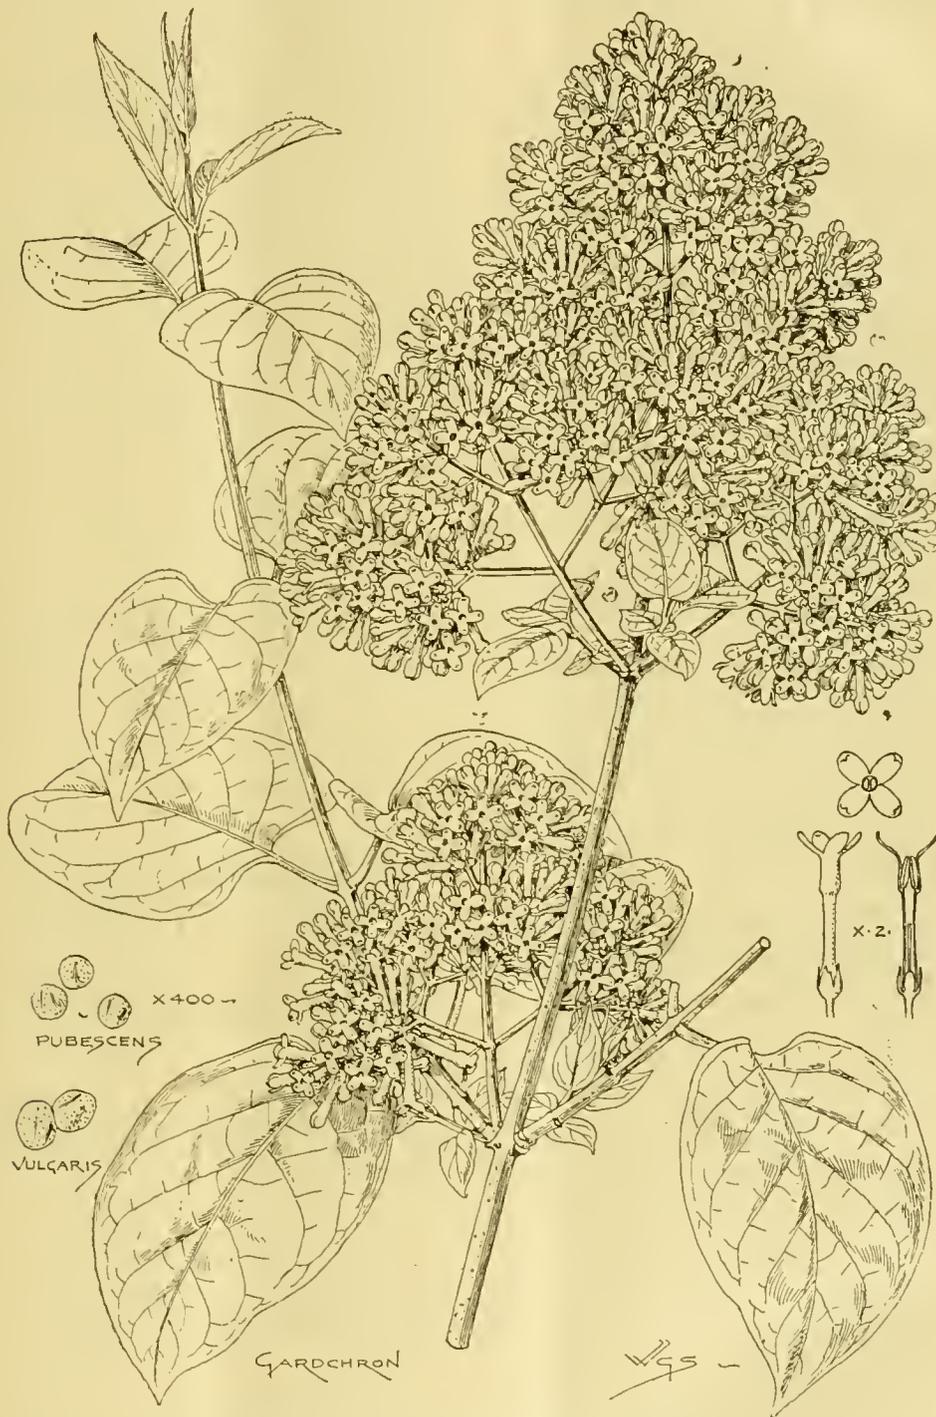

FIG. 43.—SYRINGA VILLOSA VAR. PUBESCENS. With floral details and pollen grains compared with those of *S. vulgaris*.

stated that the flowers appear early in June, and are of a rose or lilac colour, but when expanded, pale lilac or almost white. *S. pubescens*, *Garden and Flora* (1888) i. 414, and iii. (1890), 322, is described as having pretty pale lilac flowers produced in the middle of May, as in the mountains round Peking. In 1891 Professor Sargent speaks of *S. pubescens* as improving with age (*Garden and Forest*, iv. (1891), 262), and as being one of the most beautiful Lilacs in cultivation,

S. villosa in its smaller leaves, white beneath, pubescent on the midrib, and the capsules covered with warts; whilst in *S. villosa* the leaves are green and glabrous on both sides (the name being thus a misnomer), and the capsules smooth. Hooker's figure of *S. villosa* in the *Botanical Magazine* (1889), t. 7064, is referred to the small-leaved *S. pubescens*.

Rehder in Bailey's *Cyclopædia of American Horticulture* (1902, p. 1762), keeps up Vahl's species

* *Syringa villosa*, Vahl., *Enum.*, i. 38; D.C. *Prod.*, vii. (1844), p. 283; Hemsley, "Enum. Pl. China," *Journ. Linn. Soc.*, xxvi. (1889), p. 83; Bretschneider, *History of European Botanical Discoveries in China* (London, 1898), p. 1058. *Syringa pubescens*, Turczaninow in *Bull. Soc. Nat. Moscou* (1840), p. 73; Sargent in *Garden and Forest*, i. (1888), p. 415, c. ii.; Bretschneider, *loc. supra cit.*

(villosa), to which he refers as varieties *rosea*, *Cornu* *S. Bretschneideri*, *Lemoine*, *Revue Horticole* (1888), 492; *Garden and Forest*, i., 521; *Garden*, 39, p. 91; *Garten Flora*, 44, p. 500; and *S. Emodi*, an old inhabitant of our gardens.

Rehder also maintains *S. pubescens* of Turczaninow, which is the equivalent of *S. villosa* var. *ovalifolia*, D. C. In *S. villosa* the flower-panicles are said to proceed from terminal leafy branches, whilst in *S. pubescens* the inflorescence is lateral and leafless.

BOOK NOTICE.

FLORA BRASILIENSIS, Fasciculus cxxviii.

IN this part of the colossal *Flora Brasiliensis*, now nearing its completion, Mr. Alfred Cogniaux continues the enumeration of Brazilian Orchids of the genera *Quekettia*, *Trichopilia*, *Aspasia*, *Cochlioda*, *Dipteranthus*, *Zygostates*, *Ornithocephalus*, *Cryptarrhena*, *Chytroglossa*, *Phymatidium*, *Platyrrhiza*, *Sanderella*, *Gomezia*, *Odontoglossum*, *Brassia*, *Miltonia*, and *Oncidium*. The last-named constitutes one of the largest and showiest sections of Brazilian Orchids, eighty-one species being enumerated and described, many of which are favourites in British gardens, and most of them having flowered under cultivation at one time or other.

The names for which Lindley was responsible still remain in most cases unchanged, but a few departures from those in use in gardens should be noted. For example, *Oncidium Brunleesianum*, Rehb. f., illustrated in the *Gardeners Chronicle*, May 21, p. 673, is referred to *Oncidium echinatum*, Cogn. (*Baptistenia echinata*, Barb. Rodr.), as var. *Brunleesiana*. When the plant first flowered it attracted great attention, and it has always been very rare and desirable, but its exact locality was not known. It will be interesting to importers to note that *Oncidium echinatum* is recorded as from "Sierra da Tijuca, prov. Rio de Janeiro," and there is no doubt that the plant in cultivation as *O. Brunleesianum* came from that district.

Oncidium unicorn, Lindley, the singular little species bearing a branched inflorescence of yellow-and-brown flowers each with a long curved horn projecting from the centre of the labellum, is figured and described as *Oncidium longicornu*, Mutel.

Many of the species enumerated, not known in gardens, are of great interest botanically, but nothing new appears sufficiently showy to tempt those who affect showy Orchids, such as *Cattleya*, *Lælia* and *Odontoglossum*, the last-named now favourite genus being represented only by three species, viz.—*O. nævium*, Lindley; *O. præstans*, Rehb. f., and *O. epidendroides*, Kunth. The first-named elegant little species is not common, the second very rare, and *O. epidendroides* is probably not in cultivation. An interesting article from the late F. C. Lehmann on this plant appeared in the *Gardeners' Chronicle*, March 12, 1898, in which he remarks, "It may seem more than curious that this, the first-discovered species of *Odontoglossum*, the one upon which the genus was founded by Kunth, should not have been found again, in spite of more than a hundred species of the same genus having been discovered and introduced into cultivation since it was discovered by A. v. Humboldt and Aimé Boupland in the warmer region near the ancient town of Yaen de Bracamores."

Monsieur Cogniaux has done the work entrusted to him in his usual painstaking and accurate manner, and the illustrations, especially in the analyses of the flowers, are excellent, the minute details of structure which are of such importance in comparing seemingly allied species being most carefully rendered.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from p. 94.)

May 10.—With a salute of three guns from our returning life-boat we continued our journey. We passed several villages and many large farmhouses nestling in groves of *Pistacia*, *Cypress*, *Bamboos*, and *Banyans*. The tops of the hills are often clad with a few scattered *Pines*. The quantity of trees to-day, as compared with the country passed through hitherto, would incline one to write "the country is well wooded." But this would be wrong, for woods, strictly speaking, there are none, the nearest approach being small thickets of *Scrub Oak*, which sometimes cover half an acre of ground. *Aleurites cordata* is excessively common.

At 2 P.M. we crossed the Hutan rapid, one of the worst in the high-water season. Just below the Hutan is a tiny hamlet called Peh-Shui-Che, where a stream of clear water comes tumbling down a rocky slope. This stream is crossed by a bridge, the *fac-simile* of those we are all familiar with in the "willow-pattern" porcelain. The scene was a very pretty one. We moored for the night at the village of Yang-Tu.

Since entering Szechuan, one of the most striking features has been the increase in number of the *Banyan* (*Ficus infectoria*). It is now possibly the commonest tree. Usually its height does not exceed 30 or 40 feet, but the spread of its branches is enormous. This tree usually shelters some little wayside shrine. In Hupeh, *Xylosma racemosa* is the tree thus favoured.

May 11.—This was a dull, quiet and uneventful day. At 1.45 P.M. we reached Wu-ling, a village noted for its mats and tracking-lines. We purchased fifteen new mats and six tracking-lines. The mats are made of a framework of interlaced split *Bamboos*, stuffed with *Bamboo* leaves and leaves of *Sedges* and coarse grasses.

The country to-day was similar to that of yesterday, only possibly there were more trees. In places the moist grassy banks of the river were one mass of *Gentian* flowers. The whole plant did not exceed 4 inches in height, and made a lovely picture. *Salix variegata*, *Lysimachia* sp., and *Rubus corchorifolius* were the other fresh plants to-day. Two fresh trees, *Albizia Lebbek* and *Photinia serrulata*, were common. The trunks and branches of many trees were covered with *Polypodium adnascens*, and looked very fine.

The only new crop noticed was *Cotton*, and this in very small patches. *Seri-culture* continues very much *en évidence*. *Gold-washing* was in full swing in many places.

May 12.—We experienced much difficulty to-day from shallows and reefs jutting far out towards the middle of the river. We passed Shi-Pao-Che with its picturesque pagoda at 7.30 A.M., and the village of Kuan-ki at 4 P.M. We tied up for the night immediately below a huge reef some eight miles from the city of Chung. I added a few fresh plants, including—*Senecio Oldhamianus*, *Marlea platanifolia*, *Polypodium angustatum*, *Rubus chrosepalus*, *Aspidium falcatum*, *Calystegia sepium*, *Nephrrodium setigerum*, and *Scium Aizoon* var.

The commonest shrub was *Coriaria nepalensis*. *Acanthopanax ricinifolium* was a common tree. In places the banks were one mass of blue *Gentians*, in others nothing but yellow *Lysimachia*. The "Pa-tou" tree was very abundant. The tints of its foliage forcibly reminded me of the autumn hue of *Sapium sebiferum*. The people were busy transplanting *Rice*, and many fields were already finished. In places *Broad Beans* were being planted amidst the unripened *Wheat*.

May 13.—Another very hot day with practically no wind. At 4 P.M. the thermometer registered 99° F. in the shade of my cabin. At 10.30 A.M. we passed the town of Chung. This is a busy-looking place on the left bank of the

river, charmingly situated amongst trees on the side of a low hill.

Reefs continue a source of trouble and danger. At 1.30 P.M. we passed a place called Jah-Pa-Tan, where the river was nothing but a shoal of reefs.

Groves of *Bamboos* were the feature of to-day's journey, giving the country quite a tropical appearance. *Pines* and *Cypress* were also abundant. About 5 P.M. I went for a short walk and gathered a very pretty little terrestrial *Orchid* (*Spiranthes australis*). The flowers are arranged spirally. The lip is white, the rest of the flower rosy-pink. It is very fragrant. The people were busy transplanting the *Rice* plants and harvesting the crops of *Pulse* and *Wheat*. *Melons*, *Gourds*, and other *Cucurbits* were common to-day. The leaves are smeared with wood-ashes to keep away slugs.

May 14.—We were favoured with a fair wind for a considerable time to-day, and made good progress. We passed Yang-tu-Ki at 9 o'clock. This is a small village, the trade of which consists of opium and coarse porcelain. Kao-ki was reached at 4 P.M. This is a small hamlet on the right bank; its white houses nestling amongst trees on the slope of the hill look very pretty. The houses hereabouts are for the most part well-built, and the general aspect of the country and the appearance of the people fully bear out what travellers have written about this favoured province. One thing that struck me was the enormous size of the graves. These tombs are built of stone, with huge tablets in front extolling the virtues of the departed. The houses in the vicinity of these tombs are often very dilapidated, shewing that if the occupants are relatives of the deceased their fortunes must have met with a severe reverse.

The quantity of stone bridges is another feature of Szechuan. The veriest dyke has its bridge, all of which are well-built and kept in thorough repair. Ornate widows' memorial arches (*Pai-lou*) are also very common. All these things go to inform the traveller that he is in a rich and prosperous province, probably the richest of the eighteen provinces of China.

I noted that enormous quantities of *Opium* were grown hereabouts. The people were busy pulling up the old plants, the *Opium* having been collected and the seeds ripe. All the leaves had been stripped from the plant some time previously, and a secondary crop of *Maize* or *Beans* planted amongst them.

The hills are here steep and rocky, and nearly every foot of ground is under cultivation. *Aleurites cordata* is by no means so common as hitherto. It likes the steeper and more rugged hills, and it suits the Chinese to grow it there.

To-day I noted several trees of *Ligustrum lucidum*, a tree that has been scarce since leaving Ichang. *Banyan*, *Pistacia*, and *Cypress* continue the common trees. *Lysimachia ophelioides* and a species of *Salvia* were the only new plants to-day. The *Lysimachia* certainly looks at first sight more like a yellow-flowered *Swertia* than anything else. The *Salvia* is probably only a variety of the polymorphic *S. japonica*. The flowers are white, the leaves simple and (or) pinnate, red beneath. *Bamboos* continue very plentiful.

To-day has been hotter than ever; at 4 P.M. it was 92° F. in the shade.

May 15.—We were off Feng-Tu at 11 A.M. This is a small place built on a narrow strip of flat ground and backed by steep hills. Good local tea is procurable here, and most of the "Peh Mu" timber used for boat-building at Wan is shipped from here. Below Feng-Tu the hills are gentle, and all highly cultivated and bare of trees; above, the river-banks are wild and rocky, and the *Aleurites* and "Pa-tou" tree again very common. On the left bank, some distance above Feng-Tu, is a head of a colossal

Buddha carved from the solid rock. We moored for the night at San-tu, ten miles above Feng-Tu.

The feature of the cultivated vegetation was the abundance of Opium, with Maize and Beans (*Glycine*) planted to take its place. Huge Banyans with small shrines beneath them, large graves and well-built houses were the rule. *Trachospermum jasminoides* in full flower draping rocks and the trunks of the Banyans was very conspicuous.

Of new plants I noted *Mallotus* sp., *Cornus paucinervis*, *Lysimachia candida*, *Lygodium scandens*, *Clematis recta* var. *mandschurica*, and a species of *Sedum*. *Lysimachia opheloides* was very common in places.

May 16.—A few fresh plants were added to the list to-day—viz., *Sophora flavescens*, *Premna ligustroides*, *Ammania rotundifolia*, *Mallotus barbatus*, *Sedum* sp., and a curious variety of Wheat. The Wheat is cultivated, and attracted my attention by the peculiar horn-like appendage to the outer glume. It is quite normal, though I at first thought the ears were monstrous. The Chinese term it "beardless" Wheat. Opium continues the common crop. Below the city of Wan a little Opium is grown; from Wan to the city of Chung it gradually increases in quantity; above Chung by leaps and bounds, until at Feng-Tu it becomes almost the only spring crop. From Feng-Tu to Kiang-tsin it continues to be so.

The area over which Opium is the predominating spring crop amounts to about 250 miles. All the land—the foreshore and terraced hillsides—is devoted to this crop. In these parts Opium occupies the ground for six or seven months during winter and early spring. It is sown in drills in October or the beginning of November; the Opium is collected in April, and by the middle of May the ground is cleared of this crop. It is an exceedingly profitable crop, although it needs heavy manuring. It is earthed-up in the same manner as we do Potatoes, and in April secondary crops are planted on either side of the ridge, Maize, *Glycine hispida*, and Phaseolus Mungo being the favourite crops thus planted. After the Opium plants are pulled up the ground is levelled, and a mulch of manure given the secondary crops at the same moment. Occasionally "Broad Beans" are planted between the rows, and ripen with the Opium. Wheat and (or) Broad Beans are planted around the patches of Opium to serve as a shelter from wind.

The Chinese discriminate six qualities of Opium, the plants furnishing which are distinguishable by the colour of their flowers, viz.:—First quality, pure white flower; this is the earliest to mature, and is the most widely grown. Second quality, a bizarre with a central band of bluish-purple flanked with rich magenta; petals deeply incised. Third quality, white with broad flanks and apical margin of salmon-pink or magenta. Fourth quality, dark-scarlet with central band of bluish-purple to within a fifth of the apex of the petals. Fifth quality, dark bluish-purple. Sixth quality, lilac suffused with purple—a very washy colour, and considered very poor in quality indeed.

Every patch is carefully "rogued," and kept true to colour. The plants average 3 to 4 feet in height, and are remarkably even. The drier the land and the more fully exposed to the sun the finer the crop.

No crop is so gorgeous and attractive. As far as the eyes can range on every side nothing but myriads of Poppies. What a panorama of beauty!

If we except the petals and stamens, no part of the Opium plant is wasted. The oil, expressed from the seeds after heating, is used for culinary and illuminating purposes. The leaves of the plant serve as food for pigs. The old plants are either used for fuel, manure, or are burnt and soda, used for washing purposes, prepared from the ashes.

May 17.—We reached Fu-chau about 10 A.M. This is a good-sized town on the right bank of

the Yang-tsze, immediately above the point where the Kien-kiang joins it. The Kien-kiang rises in the heart of the wild province of Kuichou, and is navigable for small craft up to the city of Szé-nan, a fifteen days' journey. Fu-chau is the great *entrepôt* for Szechuan Opium, being situated right in the heart of the Opium district. It is shipped down-river from here under the native customs, and is lost to the Imperial Maritime Customs. When Wan is opened this will be altered, and a proper check kept of this produce. Silk is another important item of Fu-chau's trade. I collected several fresh plants, viz.—

Lysimachia capillipes, *Rosa* sp., *Pieris* sp., *Broussonetia Kämpferi*, *Stephanandra chinensis*, *Nandina domestica*, *Pteris semipinnata*, *Adiantum Edgeworthii*, *Clerodendron foetidum*, *Phyllostachys nigra*, and *Vicia cracca*.

The *Phyllostachys nigra* was in flower. I noted that only the flowering culms die. *Lysimachia capillipes* is a very distinct species, and is a perennial, not an annual, as stated in the *Index Floræ Sinensis*. *Cyrtandra*, not in flower, were common on the limestone cliffs, and in places the hills were a mass of yellow flowers of *Hypericum sinense*. I also noted an occasional tree of *Canarium album* cultivated.

The country is all highly cultivated and the hill-side was alive with people tilling the soil or sowing, reaping, or transplanting the various crops. E. H. W.

(To be continued.)

CACTUS SCAB.

A DISEASE caused by a parasitic fungus has long been known to cultivators of Cacti in this country, but up to the present the fungus has

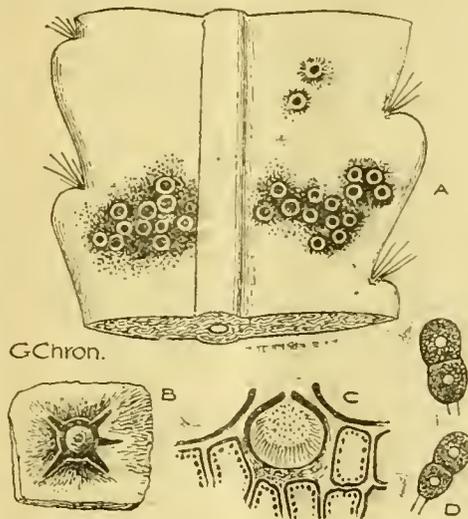

FIG. 44.—CACTUS SCAB, *DIPLODIA OPUNTIAE*.

A, Appearance of Cactus-scab, natural size; B, A single fruit of the fungus, seen from above, slightly magnified; C, section through a fungus fruit, slightly magnified; D, spores of the fungus, magnified 400 times.

not been observed in a perfect or fruiting condition; hence its identity remained in doubt. Quite recently, however, Mr. A. Worsley, Mandeville House, Isleworth, who has had the disease under observation for many years, collected the fungus in fruit growing on a *Phyllocactus*. This discovery proves the parasite to be *Diplodia Opuntiae* of Saccardo, first collected on *Opuntia nana*, in Northern Italy.

The injury caused by this fungus is sometimes severe, the black minute, wart-like outgrowths constituting the sterile portion of the fungus often covering a considerable area, the surrounding tissue becoming discoloured. The mycelium

is distinctly localised, and each scab is the outcome of an independent infection. As the *Diplodia* form of fruit is so rare, in all probability the dispersion of the pest depends mainly on the production of some minute secondary form of conidia not as yet observed. Geo. Masteë.

ALPINE GARDEN.

ALPINES AT NITHBANK HOUSE, DUMFRIES.

ONE of the most interesting collections of alpine flowers in Scotland is that of Mr. James Lotimer, Nithbank House, Dumfries, a collection which has long been known to those interested in such flowers as being one of the choicest, although not now the largest, in the North. It has been in existence for many years, and until lately, when failing health has prevented the owner from devoting to his flowers that personal attention so much needed by such plants, has contained practically every novelty of worth, and the best of the older plants. Recently, however, this cause has not only prevented the acquisition of many new flowers, but has also restricted the cultivation of some; alpine *Auriculas*, for instance, being now only cultivated in small numbers instead of largely, as at one time.

Particularly fine here is *Cyananthus lobatus*, of which some spreading masses, liberally decorated with the charming light blue flowers, appeal strongly to the admiration of the visitor. This plant does well here in various positions, perhaps the finest specimen being on a low rockery facing the south-west, but sheltered from the east by the higher slopes of the rockwork and by a good hedge behind.

Another special feature here is *Nierembergia rivularis*, a troublesome plant with many, largely on account of the avidity with which slugs devour it, and also because of the difficulty of securing in gardens the necessary amount of moisture this plant from the margin of the River Plate requires. The *Nierembergia* is not cultivated on the rockeries here, but in pans set inside zinc pails partially filled with water. The pans are stood upon inverted flower-pots, and the water is kept just at the height which will admit of the drainage of the pans being almost submerged. In winter the pans are taken out of the pails and placed on the ground, the *Nierembergia* being hardy under such conditions. The result of this treatment is that slugs are kept away and the necessary moisture is given. The plants are pictures of health and beauty, the pans being this July, as in former years, perfectly covered with the exquisite creamy-white flowers.

Another plant particularly well grown here is *Pratia angulata*, or *Lobelia littoralis*, which I have never seen finer except in the Royal Botanic Gardens, Edinburgh. At Nithbank this grows to a large size, and in whatever part of the garden it is planted it is certain to do well. It is very beautiful in such quantity, with its white flowers upon a dense carpet of green leaves hardly half an inch high. Here it does not require the semi-bog treatment that some find necessary.

Another troublesome plant in many places is *Polygonum sphaerostachyum*, which in the Dumfries district is generally a good grower, although it does not grow into large plants. It both grows and flowers freely at Nithbank.

Ramondias and *Haberleas* are well cultivated, although Mr. Lotimer's practice would not commend itself to those who like to grow their plants in the open. They are cultivated under handlights with whitened tops, by which means the necessary amount of shade is secured; while the plants are planted on the sides of a slight depression in the soil towards the centre of the portion covered by the handlight. The top of the

lights is occasionally removed, but is frequently placed diagonally across, for the admission of air. Although one does not consider this treatment absolutely necessary here, yet it must be said that Mr. Lotimer's results are excellent.

The garden is particularly rich in choice alpine Campanulas, and among these one may mention, as indicating some of those cultivated, such as the yellow and green-leaved C. G. F. Wilson, C. haylodgensis, C. pulla, C. valdensis, C. turbinata, C. Raineri, and C. pseudo-Raineri. These generally do well, and, with the taller forms, are very attractive when in bloom.

Androsaces are not so largely represented as at one time in the garden, the best being A. lanuginosa and the variety Leichtlinii, or oculata, of which there are very fine plants.

Those who like to see some of the best Saxifrages in large masses would admire the masses of S. sancta, one specimen in particular, which has been for a good many years without removal or division, being a large mass of healthy foliage, without any of the browning and decay of the centre of the plant so often seen. Others are equally good, and practically the best of the various sections are to be found, the collection being perhaps weakest in the encrusted forms. S. (Megasea) Stracheyi is a favourite for its early bloom and its free flowering.

Like a good many other Scottish growers, Mr. Locimer finds it necessary to cultivate the lovely Philesia buxifolia under a handlight, shaded from the sun, but planted in the border. Here this exquisite plant flourishes, its only fault being its tendency to bloom itself to death. The plants were very beautiful on the occasion of my recent visit, each bearing several of the long-tubed handsome scarlet flowers.

Primula species are well represented, together with the dwarf Veronicas, such as Allioni, corymbosa, and several others. Cypripedium spectabile, Orchis foliosa, the dwarf Scabiosas, Lithospermums, alpine and other species of Dianthus; Hypericums, Anthemis, hardy Erodiums and Geraniums, Iberis, and many other good alpines are practically all well cultivated. Many dwarf rockery shrubs are also grown, such as the dwarf Cotoneasters, Azaleas, St. John's Worts, and many more.

Within recent years a large number of named Rhododendrons have been planted, and these have done well this season; while a few of the finest Roses give a variety to the garden. Ferns are also well grown, and the borders contain some choice Liliiums, such as L. Humboldti and others not usually considered easy to grow. The border flowers are admirably chosen for the limited space available after satisfying the space needed for the other occupants of the garden, which has for long afforded an object-lesson of what can be done in the way of the cultivation of alpine and border flowers in this part of Scotland. S. Arnott.

FORESTRY.

THE LOCUST TREE.

I HAVE had letters from England since the questions on the usefulness of this tree appeared in the *Gardeners' Chronicle*, stating that the writer had come to realise "the value of the pseudo-Acacia by various experiments made on timber for estate purposes." This tree has also been the object of discussion in Forestry congresses held lately in Germany, declaring this tree to be most useful in many respects.

After reading the verdict of "A. P." in last *Gardeners' Chronicle*, I do not enter further into this matter, as "A. P." pretends to show "that the worthlessness as a forest tree is simply proved." But I venture to state, based upon the experiences made in England and on the Continent, that the reasons for its neglect are to be

found elsewhere, and are not the faults of the tree. On this most valuable tree I do not say anything more.

Another word to "A. P." about the Douglas Fir. My statement about the thinnings at Scone Palace, 1887, were given from letters I had from my friend Mr. McCorquodale, the contents of which were also published at that time. My statements were thus not misleading—they were based upon Mr. McCorquodale's. Anyone who knew him does not believe that he could have given false ones.

I cannot prevent English foresters depreciating the value of the Douglas Fir, as is done in the article of "A. P." To bring the great merits of this tree, however, forward (imported since nearly eighty years, 1828-29), I could not do better than refer to the last number of the *Gardeners' Chronicle* (p. 63), where Mr. J. Simpson tells us "that at the exhibition at Park Royal there was a section of Douglas Fir from Earl Powis's estate, forty years of age, varnished, showing the colour and annual rings, and indicating a stem about 24 inches in diameter; and beside this was a Larch section about 100 years old, as shown by the rings, of no greater bulk than the Douglas . . . the Douglas will produce about as much timber in forty years as the Larch will do in a hundred. . . . The heart of the Douglas was as red as mahogany." Could one state in higher terms the value of the Douglas Fir?

I have planted myself thirty years ago the Douglas Fir. I had one tree cut of exactly the same dimensions as Earl Powis's tree; 18 inches in thirty years corresponds with 24 inches in forty years; the heart also two-thirds red as mahogany. From this plantation I sent, years ago, thinnings to my late friend, Professor Dr. Robert Hartig, and after scientific investigation he declared the wood Larch-like, and gave the following classification:—

Larch I., Douglas II., Pine III., Spruce IV., Fir V. John Booth, 39, Mozartstrasse, Gross-Lichterfelde, Berlin, July 24, 1905.

THE LOCUST-TREE.

Like Mr. Simpson I feel that if I had 1,000 feet of Locust timber for sale, I should experience considerable trouble in finding a purchaser. Whatever the capabilities of the tree may be or the demand for its timber in Germany, it is simply its proved worthlessness generally as a forest tree in this country that is accountable for its neglect.

It is, however, to Mr. Booth's reference to the Douglas Fir that I have a word to say. From Mr. Booth's letter it is evident he has no practical knowledge of the conditions of British forestry, and although I do not quite agree with the low estimate Mr. Simpson places upon Douglas timber, I must say he is very much nearer the mark than he who would put him right. It is too early to say what the price of Douglas timber may be when fairly mature wood in considerable quantities can be placed on the market. Up to the present time it is only coarsely grown, immature trees that have been disposed of at irregular times, at much lower prices even than Mr. Simpson states. But I have been offered as much as 9d. per foot for clean, well-grown trees.

I have not the *Gardeners' Chronicle* of 1888 nor the *Perthshire Constitutional* of January 11, 1888, to refer to, but I am astounded to hear that such misleading statements as Mr. Booth quotes should have appeared in these papers.

In 1887 there were thinned out of Taymount Wood 680 Douglas Fir trees. These, if of the size given, viz., 27 cubic feet each, would give a total of 18,360 cubic feet, which at 1s. per foot would realise £918, an excellent result. The real facts of the case, however, were not so encouraging. The 680 trees were sold by auction for

£34, a very much less valuation than even Mr. Simpson would allow.

Mr. Booth's concluding remark would have been instructive had he given us his own opinion as to the causes affecting the prices of Spruce and Douglas timber, and his reasons for holding his opinions. A. P., Perth, July 17, 1905.

THE CANNING BUSINESS.*

To build and "operate" a canning business on large commercial basis belongs to the domain of the expert with ample capital; but fortunately there are means and methods by which any small farmer or enterprising individual, whether farmer or not, can very successfully build up a canning business for himself, provided he will go about it intelligently.

The outfit consists of a specially constructed galvanised-iron boiler, made to fit either a No. 7 or No. 8 cooking stove, a basket or carrier that fits inside the boiler, can-tongs, and soldering-irons. This is a very simple yet economical and accurate form of the "open process" method of canning.

The operation of the outfit is very simple and quickly learned, and the principle all the way through is the same as that followed in regular canning establishments.

In canning Tomatos the first step is to scald the fruit just sufficiently to loosen the skin, so that it can be slipped off. To do this we use a large iron kettle, commonly called a wash pot. The Tomatos are placed in a cheap tin vessel that has been punched full of small holes, and holds about one-third of a bushel. This is dipped into the boiling water and allowed to remain about one minute, or until the skin will slip readily. The fruit is then peeled, sliced, and filled directly into the empty cans. The cans must be well filled for good results. This finishes the first step. The filled cans are then passed to the second stage of the operation. The tops of the cans are wiped dry with a clean cloth, the cap placed on and soldered around the rim. The small hole or vent in the centre of the cap is left open. Then we are ready for the third step, that of exhausting—expelling the air out of the cans. This is accomplished by submerging the cans in the boiling water (in the boiler) about two-thirds of their length. They are held there until they come to a boil, or for Tomatos ten minutes. They are then removed, the small hole in the centre of the top closed with solder, and the cans are then completely submerged in the boiling water and boiled or processed twenty minutes, which is the fourth and last step in the operation.

Then, summed up, the different steps or stages of the complete operation are as follows:—(1) Scalding, peeling, and filling; (2) wiping and soldering the cans; (3) exhausting and tipping; (4) processing or cooking.

The scope of the work of home-canning is almost unlimited. The canner can be run almost constantly from May until November. Beginning in May with all kinds of berries (especially Strawberries and Blackberries), we go right on through the summer with vegetables and fruits, and during the fall with Sweet Potatos. A list of the leading fruits and vegetables that can be successfully put up are as follows: Fruits—Strawberries, Blackberries, Peaches, Plums, Pears, Apples, Figs; vegetables—Tomatos, Beans, Okra, Sweet Potatos. Peas and Corn cannot be very successfully canned on an outfit of this kind, as they require a higher pressure than the above, and for this purpose the closed kettle is necessary.

Undoubtedly the chief value of an outfit of this kind lies in the opportunity afforded of utilising the surplus that cannot be profitably

* Extracts from a paper by E. J. Watson in a Bulletin issued by Agricultural Experiment Station of the Louisiana State University.

shipped to market. With Tomatos and Peaches, and often with nearly all kinds of vegetables and fruits, the period wherein profitable shipments can be made comes to an end before the crop is exhausted. Therefore what remains need not be lost, but is turned into a nice profit by canning.

We also put up a quantity of Peaches plain, or in their own juice; these do not require any sugar, but simply clear water. This grade must be sold as pie Peaches, and the prices are about \$1.00 per dozen.

Pears are put up in the same way as the Peaches, at about the same cost. The prices for the finer grades are the same as for the Peaches.

We found that the Pears yielded a larger profit than the Peaches, other things being equal, as 1 bushel of Pears filled an average of twenty-four 3-lb. cans, and 1 bushel of Peaches only sixteen 3-lb. cans.

COLONIAL NOTES.

THE WATER HYACINTH IN QUEENSLAND (EICHHORNIA SPECIOSA).

DURING the three years ending in 1849, which I spent in the Royal Botanic Gardens, Regent's Park, London, I had in a tank in the Orchid-house several plants of the above species, but they never flowered. I little thought then that I should ever have the opportunity of seeing a mile or more of a lagoon, in places more than 200 yards wide, covered by it, and in flower all summer. I may say the plant blooms nearly all the year, but in summer it is in its glorious dress. I can never give a proper idea of the grandeur of the sight. Not only is the scene magnificent from its very magnitude, where every square yard may carry twenty flower-spikes, but when one of the flowers is examined in the hand then one sees the purity and delicacy of the colours—violet, purple, blue, and bright orange.

A few years ago it was introduced by some means into a pond close to one of the sugar mills on the side of the lagoon, and about two years later it found its way into the lagoon, and from the mill down to its outlet in the Pioneer river it is one mass, and it seems to me the species has a good chance of smothering the beautiful *Nymphaea grandiflora* which grew there abundantly, with many other aquatics, *Vallisneria spiralis* among them.

The "Hyacinth" has come to stay, and I have no doubt the other species will have to give way, but so far as a great aquatic display is concerned, the inhabitants have not much to complain about, except the consequent loss of variety. The lagoon was a favourite resort of many aquatic birds, black swan, geese, pelicans, a variety of the stork genus, ducks in thousands, with a host of smaller birds; but although there is still an open stream in the middle where the water is very deep, there is little doubt but that even this piece of clear water will be covered, then the birds may walk on the top, but it is not likely that will suit them. When I first took charge of this nursery there were several acres of the lagoon partially covered by a floating grass; the whole substance was not more than a foot thick, and the bottom portion was mud, and yet a number of cows and horses could walk about and graze on it, and I knew only one horse go through it. This accident gave me a good deal of trouble, for it was just in front of my house, which was on the bank, and I knew the horse must die and that we should be poisoned by the smell of its decaying carcass. There was nothing to be done but to cut a passage through the floating substance out to the clear opening with a hay-knife, and by the help of the boat the horse was dragged down till we got to a place where we could clear a track where he could walk out as soon as his feet touched the bottom. We wanted to see the clear water and the *Nymphaeas* and the birds, but our enjoyment was

short-lived, for *Anacharis alinastrum* very soon took its place.

Azolla rubra formed large patches as it was driven to lee by the wind, making the surface of the water a bright red, and it is still struggling for an existence among the Hyacinth. The Hyacinth would no doubt flower in English tanks [It does. Ed.] if it had all the sunshine that could be given it. Here, on December 21, our longest day, the plant had sunshine soon after 4 A.M., and it continued until nearly 6.41 P.M. At that time of the year the sun's direct rays vary from about 160° to 176° at midday. *D. Buchanan, Mackay, Queensland.*

PLANT NOTES.

CRASSULA COCCINEA IN THE OPEN.

In the month of July the gardens at Tresco Abbey, Isles of Scilly, glow with great masses of this brilliant South African plant in full flower. It is a favourite for conservatory decoration from its bright colour and its sweet scent. In the Isles of Scilly it is perfectly hardy, and I saw it three years ago doing well in a friend's garden in the neighbourhood of Penzance, where it is absolutely unprotected during the winter. After

FIG. 45.—DIMORPHOTHECA AURANTIACA: FLOWERS ORANGE-COLOURED.

DIMORPHOTHECA AURANTIACA.*

For the opportunity of illustrating this South African plant we are indebted to Mr. Gumbleton. It is a glabrous perennial, with linear-oblong thick leaves and solitary heads, like those of a Marigold, of very vivid orange colour. The bracts of the involucre are linear, acute entire, with a line of rough hairs along the centre.

Messrs. Barr & Sons, who introduced the plant, tell us that the flowers only expand in the sun, and are then very pretty, being of a glossy golden-salmon, with black central ring. The plant grew with them 9 inches high, and continued flowering for a long period.

* *Dimorphotheca aurantiaca*.—*D. C. Prod.* vi. (1837), p. 72, Klein, Namaqualand. *Calendula Tragus*, *Botanical Magazine*, t. 408; flowers yellow.

seeing it in that garden I procured a good plant and put it in the open, where it has passed through two winters without damage. It is now in full bloom, and is bearing thirty-seven flower-heads, the largest of which is about 5 inches across. It makes a vivid spot of colour in the garden, its bright hue being intensified by a plant of *Campanula pelviformis* growing close by, about a hundred of whose saucer-shaped, French-gray flowers are now expanded.

ARGEMONE GRANDIFLORA.

Considering its great beauty it is surprising that this plant is not more grown, but it is rarely met with in gardens. Its flowers are very much like those *Romneya Coulteri*, being white, with a central bunch of yellow stamens. They are, however, considerably smaller, being about

4 inches across, while a bloom of the *Romneya* that I measured this morning was 7 inches in diameter. The first flower of the *Argemone* expanded on June 23, and it will continue in bloom for a good four months. The flowers last little longer than a day, but are produced in such profusion that their fading is unnoticed. This morning I counted forty-one expanded blossoms on my plant. The *Argemone* is generally considered an annual, but my plant threw up strongly from the base this spring, and is now 4 feet in height and as much through. The grey-green, spiny leaves associate charmingly with the pure white flowers, and the plant makes a pretty picture for many weeks. *S.W. Fitzherbert, South Devon.*

THE ROSARY.

CLASSIFICATION OF ROSE SPECIES.

To the number of the *Journal of the Linnean Society* lately issued, Mr. Baker contributes a revised classification of Roses (1905). The catalogue now published includes the names of the species, varieties, and principal hybrids, but does not attempt to enumerate the innumerable garden-forms, and is intended to replace that given in our columns by Mr. Baker on August 15, 1885, p. 199, and reprinted in the *Journal of Botany* for the same year, p. 281.

The principal groups are enumerated in the following table, the total number of species admitted being sixty-eight, with numerous varieties and still more numerous hybrids.

ANALYTICAL KEY TO THE GROUPS.

Leaves simple, exstipulate ...	I. <i>Simplicifoliæ</i> . [1]
Leaves compound, stipulate.	
Styles united in a column which is protruded beyond the disk ...	II. <i>Systylæ</i> . [10]
Styles free, not much protruded.	
Stipules free, deciduous...	III. <i>Banksianæ</i> . [3]
Stipules adnate to the petiole.	
DIACANTHÆ.	
Prickles often in stipular pairs.	
Fruit persistently hairy. Bracts crowded, deeply incised ...	IV. <i>Bracteatæ</i> . [2]
Fruit glabrous.	
Hip green, with a thick skin ...	V. <i>Microphyllæ</i> . [1]
Hip red, with a thin skin ...	VI. <i>Cinnamomeæ</i> . [21]
HETERACANTHÆ.	
Prickles scattered, very unequal.	
Larger prickles long, slender, straight...	VII. <i>Spinosissimæ</i> . [8]
Larger prickles hooked, stout ...	VIII. <i>Gallicanæ</i> . [2]
HOMOCANTHÆ.	
Prickles scattered, uniform.	
Leaves glabrous or slightly hairy ...	IX. <i>Caninæ</i> . [8]
Leaves very hairy ...	X. <i>Villosæ</i> . [5]
Leaves very glandular beneath ...	XI. <i>Rubiginosæ</i> . [8]

The figures in the brackets following the names of the groups [8] indicate the number of primary species they contain.

FOREIGN CORRESPONDENCE.

YOKOHAMA.

MR. REGINALD J. FARRER, author of the *Garden of Asia*, when travelling in Japan three years ago, visited the Nikko mountains early in May. He wrote to me from there glowing descriptions of the hills, and of the spring-time flowers, but his unbounded admiration he reserved for the mountain Azalea, which he said if he had its naming should be called Azalea "gloria." This year all vegetation was late, so that it was not until the end of May that I found the Azaleas blossoming in all their glory. They grow in masses,

along the last part of the road leading from Nikko to Lake Chuzenji (4,373 feet above the sea-level), and the colours range from the most delicate white and light pink to a dark pinkish-purple. The bushes are 20 to 30 feet high, and are certainly very old. They grow as undergrowth under large trees and between stones, and it is rather difficult to get plants that will continue to thrive.

Years ago we brought down many of these bushes, planting them in our garden here, where all but one succumbed to the damp, hot climate of Yokohama. Owing to Mr. Farrer's inducements, however, I have now made arrangements to collect some again direct from the mountains, keeping them there until the shipping season arrives. Thus I hope to be able to satisfy Mr. Farrer's wish of introducing these Azaleas into England.

Higher up, at Lake Yumote (5,000 feet), the *Rhododendrons* (*R. Metternichii*) showed their blossoms. The blossoms are a delicate pink, exceedingly beautiful, but, like the Azaleas, good specimens are difficult to obtain. *Glauclidium-palmatum* (Jap. nom. Shirane Aoi) was also flowering in Yumote—a lovely blue blossom, which should be grown in every alpine garden.

Another jewel of the Nikko range I discovered at a small garden in Nikko, namely, a tiny *Cypripedium* (*C. debile*), of which I sent you a pencil sketch, natural size, by the last mail. The flowers are not larger than a Pea, and hang from a two-leaved stem about 2 inches long. I have instructed the man to gather more of these for me, and I shall send them to Kew and to Mr. Farrer, and hope that they may succeed in cultivating them successfully, and in showing them in one of the Horticultural Society's meetings. *Alfred Unger.*

The Week's Work.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to LORD HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Zonal Pelargoniums.—The propagation of the varieties should be commenced by the middle of the present month. Where a large quantity is required, it will economise space and labour to use boxes about 20 by 15 by 3½ inches, with ample drainage holes. A box of this size will accommodate forty-eight cuttings. Put some rough material in the bottom, then press firmly in a mixture of sandy loam and leaf-mould. Over this spread a layer of sand, but leaving ½ inch of space at the top for convenience in watering. With a sharp knife make the cuttings 9 inches long, and dibble them in firmly without bruising them. Place the boxes in a sunny position on a trellis a few inches from the ground. Saturate the soil well; afterwards a moderate amount of moisture will be sufficient. Ivy-leaved and sweet-scented Pelargoniums can be treated in the same manner. Geld, silver and bronze-leaved varieties, also tricolor varieties, require more careful treatment, especially in cold and wet localities. It is safer to put the cuttings in pans or in 8-inch pots, and to place them in well-ventilated frames.

Violets.—Keep the foliage healthy and free from red-spider by syringing the plants vigorously two or three times a week. Use a reliable insecticide, such as "Spidaicide," if the pest is persistent. Some varieties, if allowed, would send out a quantity of runners. Keep them pinched off as they appear.

Borders of Herbaceous Plants, &c.—Anticipate the wants of tall-growing plants by affording them stakes in good time. Herbaceous Lobelias and Phloxes require an abundance of water. Any extra effort in this way will be well repaid by larger trusses and a longer flowering period.

Eucryphia pinnatifolia is a deciduous shrub with distinct Rose-like foliage of a deep glossy green colour. The flowers are 2½ to 3 inches in diameter, with pure white petals and numerous golden anthers. They are produced in July and

August. It makes a good wall-plant, thrives well in sandy peat, and requires sunshine and shelter from strong winds.

Abelia rupestris is a desirable wall-plant, flowering from August onwards; it has pale pink, tubular, sweet-scented flowers. A loamy soil suits the plant, and it can be increased by cuttings inserted at the present time.

Hibiscus syriacus (*Althea frutex*).—The many varieties of this ornamental autumn-flowering deciduous plant are useful for planting against walls and in warm corners. The plants will grow in ordinary garden soil.

Azara microphylla is a neat plant for walls, and will thrive as a standard in sheltered, dry positions.

Potentilla fruticosa is a native shrub with dark-green foliage, and produces numerous yellow flowers in August and onwards. It will grow in any situation.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to SIR FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

The *Mexican Lælias*, of which *L. anceps* and its varieties are the most important, should now be making sturdy progress, and in consequence must not suffer from lack of water at the base or moisture in the air. The daily treatment during fine weather should be as follows:—Increase the ventilation early in the day; afford water to those plants approaching to a dry condition soon after 9 o'clock A.M., and afterwards give them a good syringing. As the sun increases in power lower the blinds, which should be thin in texture or made of laths. About 3 o'clock P.M. remove the shading, give another good syringing, and close all the ventilators for about three hours, after which they may be opened again for the night. The extent to which they are left open must be determined by the force and direction of the wind or other conditions, but so long as the temperature outside does not fall much below 50° no harm should happen to the plants inside. During dull and wet weather considerable modification of the above treatment should be adopted, especially in the matter of spraying and watering. It is a noteworthy fact that plants of the *L. a. Sanderiana* section always produce floral scapes more freely from those growths which start late in the summer than from such as grow early in the season.

Lælia autumnalis and its variety *alba* are late-growing kinds that develop rapidly once they have started, but need to be kept dry until that time. When roots are appearing fresh peat and sphagnum-moss may be afforded, afterwards increasing the supply of water until the pseudo-bulbs are almost their full size, when the supply should be again decreased. The same remarks apply to *L. albida*, *L. Gouldii*, *L. furfuracea*, and *L. Eyermanniana*. *L. usajalis* has completed its bulbs, and will need full exposure to the sun and air, with daily syringings.

Miscellaneous.—Plants of *Cœlogyne cristata* should be afforded liberal supplies of water whenever the soil shows signs of drying. Old-established plants would derive benefit from occasional applications of weak liquid farmyard manure, or a solution obtained by placing a sack containing cow-dung in a tub of rain-water. Syringe the plants over twice a day whenever the weather is fine. *Pleiones* now completing their pseudo-bulbs may also be given an occasional application of manure-water. As the tips of the leaves decay, cut them off, or damage may be done to the healthy parts by contagion. The rooting medium should be afforded a moderate amount of water so long as the leaves remain; but when the new growths containing the floral scapes appear a very limited quantity will suffice. *Cœlogyne Schilleriana*, closely allied to the above, should, as soon as its tiny bulbs have developed, be removed from the warm-house to a lighter position in a *Cattleya*-house, keeping the plants well supplied with water so long as the leaves remain fresh. Like the *Pleiones*, this plant is deciduous. All *Vandas*, *Acrides*, *Angraecums*, *Saccolabiums*, &c., of a similar nature, will need a plentiful supply of water during the present month and in September, but spraying overhead should be omitted when the conditions are unfavourable to rapid evaporation. *Cattleya* and *Lælia*-*Cattleya* hybrids should

have their needs attended to as they attain to a suitable condition for potting, &c. They are so numerous and varied that it is impossible to do anything but generalise as to treatment. Such as L.-C. callistoglossa, L.-C. Henry Greenwood, L.-C. Dominiana, &c., however, which flower as soon as the growths are nearly completed, may be potted as soon as new roots are expected or have appeared, treating them carefully in the matter of water for some little time afterwards.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Onions.—To obtain plants to stand through the winter seeds should be sown from the middle to the end of August. The general result of too early sowing is that a good number of the plants run to seed, and may be considered worthless unless for immediate use. Suitable varieties for sowing in August are Giant Rocca, Giant White Tripoli and Ailsa Craig. Sandy soil that is well drained and manured will be found most suitable for Winter Onions. The drills should be drawn about 1 inch deep and 1 foot apart. When the plants appear above ground keep a sharp outlook for worms, which not unfrequently draw them down into the soil. Lime is the best remedy to use against this evil. Onions that were raised early, if intended for exhibition, should be freely supplied with water and occasional doses of liquid-manure. In order to secure perfect finish, a clear, bright, pale-straw-coloured skin, firm and solid round the neck, remove all brown or decaying skins as they appear, and see that the bulbs are not buried too deeply in the soil. Remove all decaying matter from underneath as well as on the top, so that light and air may pass freely under the bulbs, and thus secure that clean, fully-matured condition which adds so considerably to their appearance upon the exhibition table.

Turnips.—Continue to sow seeds for producing Turnips in quantity in autumn and early winter. Give daily attention to the young plants as soon as they appear, and where the lawn-sprinkler cannot be used to keep the fly from destroying the plants, dust them with wood-ashes early in the morning while the dew is upon them. Plants raised from earlier sowings will now be growing rapidly, and thinning should be done as soon as this is necessary. A variety having sweet tender white flesh is Early Snowball.

General Work.—Attention will now be required by all the newly-planted crops, such as Winter Greens, Endive, Lettuce, &c., and particularly late crops of Peas, which should be given soakings of water, also spray the plants with water as late in the day as possible. Hoeing and mulching the surface soil, with applications of water in addition, are the best means of prolonging the crops when the rainfall is short. Autocrat and Gladstone are the most reliable varieties.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Early Vines.—If the foliage of early Vines which were cleared of fruit in June is quite clean, less syringing will now be required, but it may be done occasionally after a hot day with advantage. The laterals having been allowed to grow a little may now be shortened to encourage the wood to ripen thoroughly. Examine the borders whether outside or inside, and if it is known that the drainage is in good condition, liberal applications of water may still be given. If, however, any of the borders are in an unsatisfactory condition, the sooner they are renewed the better, because the Vines will then have time to make fresh roots while the foliage is still healthy. The roots may only require to be lifted, in which case a portion of the old soil may be returned, with an addition of fresh compost to lay the roots in. It is often owing to insufficient waterings that the roots penetrate deeply in search of moisture, and they can only be brought to the surface again by lifting. Get a sufficient quantity of soil in readiness to complete the work; using a compost similar to that recommended in the Calendar for April 29, with a slight addition of Vine

manure according to the quality of the loam that is being used. Afford water to the border a few days previously, and when commencing the work get out a trench at the greatest distance from the Vines, gradually working out the old compost with a fork, and taking great care not to damage the roots, which must be tied up in bundles and kept moist until they are laid in the new soil. See that the drainage is in proper condition, placing new turves, grass side downwards, over the material to form the base, making each layer firm afterwards as the work proceeds until all is finished. Examine the roots, and remove all injured parts. Shorten some of the strongest, and spread them out evenly at different depths near to the surface. Shade the Vines, and syringe them frequently while the work is in progress. If the roots are growing outside and inside, and one of the borders is left undisturbed, no check to the Vines will be noticeable this season. Apply a good covering of rough litter to the border, in order to retain the warmth. Do not force the Vines severely next season, but give them time to recover.

Pot Vines.—The earliest plants which are intended for starting early in November will soon have completed their growth. Keep all laterals in check, and gradually reduce the supply of water at the roots as the Vines show signs of ripening. Stand the plants in a cool, fully-ventilated house, or place them against a south wall, securing the canes to supports to prevent them being damaged by winds. Prune the Vines as soon they are ready for the operation, and keep them cool and moderately dry until required for starting, or until there is frost.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Bulbs.—In order to obtain a useful supply of flowers for cutting from October onwards, it is necessary that a start be made in the present month with the earliest bulbs that are obtainable. Roman Hyacinths, Narcissus, Snowflake, Freesias, &c., which are the first to be had, should be potted as soon after they are received as possible, and when they have been given a good watering applied through a rosed watering-can, plunge the pots containing the Hyacinths and Narcissus in ashes, allowing them to remain there until the bulbs have made 1 inch of growth. Let the Freesias be stood in a cold frame, slightly covering the surface of the pots with sifted leaf-soil or Cocoanut-fibre, which should be removed as soon as growths begin to show through.

Lilium candidum, if given proper care and attention, will flower from February onwards either in pots or boxes. The bulbs should be procured now and potted up without delay, leaving sufficient room at the top of the pots for the application of a top-dressing at a later date. Stand the pots in a cool frame, and water the soil once. Towards the end of November many of the bulbs will be ready for starting into growth. At no time must hard forcing be resorted to. My practice is to place a batch in an early-startedinery, the conditions of which suit the bulbs admirably, and to let them remain there until the flower-buds are formed, when if necessary more heat is afforded to hasten the production of flowers. After flowering the plants should be hardened and planted out in the grounds.

Cyclamen.—Seeds should be sown at the present time, using as a compost finely-sifted potting soil in well-drained pots or pans. Let the pans be placed on a shelf near to the light, in a warm moist atmosphere, where they can be shaded from bright sunshine.

Other Seeds.—Seeds of *Browallia speciosa* major, *Lobelia tenuior*, *Schizanthus* in variety, &c., should also be sown for flowering in the early spring, raising the plants in moderate heat.

Begonia Gloire de Lorraine.—The plants earliest propagated are now in a condition to be given liquid manure at the roots. This should be afforded often and much diluted. For ordinary decorative purposes pots 6 inches in diameter are large enough. Continue to tie in the growths by slinging them to one centre stake, and do not allow the plants to be crowded toge-

ther. Remove the flowers as they appear until it is desired the plants should bloom.

General Remarks.—Let *Salvias*, *Bouvardias*, zonal *Pelargoniums*, &c., intended for autumn flowering, be given copious supplies of liquid manure, and a slight dusting of Clay's Fertiliser once a week. Pinch out the flower-buds of *Bouvardias* once more.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Raspberries.—Directly the fruit has been gathered, remove the old canes close down to the ground with a sharp knife, and if the young canes which are left for fruiting next season are too numerous, thin them out at the same time, so that they may have the benefit of a greater degree of sunshine and air. Five to eight canes are quite enough to leave, either for tying to trellises, for arching, or for other modes of training that may be adopted. If they are to be tied to upright stakes, three or four canes will be sufficient; but generally in this case the stools are planted closer together.

Autumn-fruiting Varieties.—The young canes of these should be well thinned out, and in some cases where growing very strong they throw out lateral growths, which should also be removed.

Strawberry-beds.—Any ground now occupied with plants that are not to be kept for further fruiting should be cleared, and it will be found quite suitable for producing good crops of Kales or Broccoli without further preparation. Ground intended for plants required to fruit next season, and which has not previously been prepared, should be commenced on at once, trenching the soil and working into it two layers of well-decayed farmyard manure. The rooted runners should be planted out by the middle of the present month if the best results are to be had next season. Alpine varieties will now be fruiting freely, and may advantageously be given a good soaking with water.

Examine *Cherry trees* from which the fruit has been gathered, and cleanse the foliage of black-fly. If pyramids are badly attacked at the extremities of the shoots, remove the extremities. Trained trees should have their branches neatly secured to the wall or fence. Carefully examine the trees and see that there are no ties which will cut the bark, and thus produce "gumming" and loss of the branch. Thoroughly saturate the soil about the roots with water if it is at all dry.

Currants.—The shoots of Red Currants should be topped where this has not been done already. If the fruit is required to hang long the removal of such "tops" will help to keep it clean, removing as it does the insects whose excrement adheres to the fruit.

Fruit stocks for budding, owing to the dry weather, are not in the best of condition for the process, and where it is found the bark does not part easily from the wood, a good soaking of water should be applied to the roots a day or two previous to "working" them. Select the buds from growing shoots, because difficulty is sometimes experienced in removing the wood from the bud if growth has ceased. Growths which are very sappy must be avoided also.

PUBLICATIONS RECEIVED.—*Annual Report on the Botanic Gardens, Singapore and Penang*, for 1904. By H. N. Ridley, Director of Gardens, Straits Settlements. The new building, for the Herbarium and Museum, was furnished as far as funds would permit, but more cases are much required. Many additional specimens were acquired. In the Economic Gardens experiments were made with fibre and rubber plants.—From the Imperial Department of Agriculture for the West Indies: *Report on the Experiment Station, Tortola, Virgin Islands*, 1904-5. Useful experiments were again carried on in the experiment plots with Sugar-cane, Onions, Cacao, Pineapples, Limes, Corn and Cotton. The peasants arc, fortunately, taking up the cultivation of Cotton.—Laves' Agricultural Trust. *The Rothamsted Experiments*. Plans and summary tables, arranged for reference in the fields, 1905. *The Analysis of the Soil by means of the Plant and calcium cyanide*. By A. D. Hall.—From the *Journal of Agricultural Science*, January, 1905 (Cambridge University Press). *On the Accumulation of Fertility by Land allowed to Run Wild*. By the same author, and published under the same conditions as the above-named pamphlet.—From the Agri-Horticultural Society of Madras: *Rules and Regulations of the Society, Price List of Flower and Vegetable Seeds, The Annual Meeting, March 31, 1905; Proceedings of the Society, January to March, 1905.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Gardens of Sweet-smelling Flowers.

WHY do we not more often meet with a garden which is something more than a purely "show" garden—one filled with fragrant flowers and foliage, enclosed within shrubs and low-growing trees? Such a garden would find countless admirers, and the members of a family once possessing such a treasure would retain a recollection of its homely delights their whole life long.

We hold in remembrance an old-fashioned garden on a nobleman's estate that was planted on the lines here advocated. A long border, perhaps 150 yards in length, was divided into beds of 4 feet in width running from the front to the back of the border. These were each planted with one species. There were the shrubby Honey-suckle, *Lonicera xylosteum*; Violets, such as the Neapolitan; single and double flowered Carnations of the florists' varieties, clove-scented Pinks and Picotees, the true wire-edged sort, now less common than formerly. The larger-flowered *Mimulus*, prepared in large pots, were set out freshly every year, and possessed the true Musk odour; the small-flowered Musk being much more powerfully scented than the vaunted Harrison's variety, and therefore greatly valued, perfume in a Musk being of greater importance than size of bloom. *Polyanthus* with a delicious fragrance, Moss, Provins, and Centifolia Roses were also included. Tea-scented

Roses were at that time but little known, but there was Devoniensis, then just brought into commerce. Most of the best hybrid Perpetuals at that time were noted for their fragrance, as is not always the case with the later introductions. These were grown either in the beds or as "pillar" Roses at the margin of the border. Bulbs of various species found a place, and there were hundreds of the Pheasant's Eye or Poet's Narcissus, Jonquils, and Tazettas. What a show could now be made with the new hybrids, many of which are also fragrant.

Some beds were prepared annually for planting with Brompton and Ten Week Stocks, with Wallflowers of the dark brown-coloured single varieties, with *Martynia* fragrans, whose handsome *Gloxinia*-like purple flowers have sweet fragrance. There was always a bed or two set apart in May for *Salvia patens*, which bore a profusion of its lemon-scented, broad, blue flowers. *Hepatica triloba*, white and blue-flowered, was used as edging to some of the beds, and golden-leaved Thyme and *Thymus lanuginosus*, a very close-growing creeping species, to others. Masses of Bourcault and Ayrshire Rambling Roses, of the common Jasmine and of *Clematis Flammula*, with its balsamic aroma, grew on walls and the tall trellises adjacent. This old border would have been rendered still more delightful had it been faced with a similar one planted with shrubs having sweet-scented flowers or leaves. Of such may be enumerated Sweet Verbena (*Aloysia citriodora*), *Buddleia globosa*, tree Ivies, herbaceous *Pæonies*, some varieties of which are pleasantly fragrant; the Chaste bush (*Vitex Agnus-castus*), *Calycanthus floridus* (Carolina Allspice), Lilacs in variety, *Philadelphus coronarius*, and others; the baccate-fruited Crabs, Ghent Azaleas, most of which have a refreshing fragrance, especially when planted in masses together; *Daphne Mezereum*, *D. cneorum*, and Sweet Briars, of which we now have so many varieties, beautiful alike in blossom and in fruit.

There are several evergreens, some of which are sweet-scented, not the least important of which are the common Bay, *Laurelia aromatica*, if it could be procured; Lavender, *Daphne Blagayana*, *Mahonia Aquifolium* and other species of *Berberis*, *Eleagnus angustifolius* and *E. argenteus*.

In conclusion, it may be said that in addition to sweet-scented annuals, the scented-leaved varieties of Cape Pelargonium, *Heliotropes*, &c., could be fittingly introduced into such a garden for summer flowering; and the names of many other suitable fragrant plants will occur to those readers who are conversant with plants. At the present time too much attention is bestowed on form and colour and too little to fragrance.

CAMPANULA MICHAUXIOIDES (see Supplementary Illustration).—This species was originally described from specimens gathered on Cadmus mountain in Caria, and its botanical characteristics are fully set forth in Boissier's *Flora Orientalis*, v. (1875), p. 938. The lower leaves are like those of *C. alliariæfolia*, the flowers are nodding, about the same size as those of *C. rapunculoides*, with the lobes of the corolla spreading like the rays of a star, and ultimately reflexed as in *Michauxia campanuloides*. The root is fleshy, and might probably be used in the same way as "Rampions."

In the specimen at our disposal, the milky juice characteristic of the genus was specially abundant. Our illustration was made by Mr. Worthington Smith from specimens obligingly furnished by Mr. Goodwin, whose note on the plant is here subjoined:—

"This is an interesting biennial species from Asia Minor, which reached English gardens through the agency of Messrs. Haage & Schmidt, of Erfurt, who first distributed seed about three or four years ago. It has proved perfectly hardy with me, growing in an herbaceous border, and flowering from about the end of May till the end of June. The plant is of tall, slender growth; the flowers are a dull, pale blue, with the corolla cut down to the calyx-tube into slender segments. Its height (my tallest plant is over 5 feet) and the light way in which the flowers are disposed gives it rather a graceful appearance, but as a garden plant it perhaps needs improvement, as too few of its flowers are out at the same time. The Kew authorities inform me that it flowered with them for the first time last year. My plants have already ripened plenty of seed. Arthur R. Goodwin, *The Elms, Kidderminster.*"

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Society's Committees will take place on Tuesday next, August 15, when a lecture by Professor J. CRAIG, of Cornell University, on "Orchard Management" will be given. The lecture will be illustrated by lantern-slides.

The Council of the Royal Horticultural Society have decided to hold a trial of Tulips of all kinds at the Society's Gardens at Wisley during the season of 1906. The trial will be open to amateur and professional gardeners as well as to the trade. At least six bulbs of each variety entered must be sent. These must be duly named, and accompanied, when possible, by a short description of the origin of each variety, and a note of the class of the flower to which it is considered to belong. If by post, the bulbs should be addressed to the Superintendent, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey; or if sent by rail, the Superintendent, R.H.S. Gardens, Wisley, to Horsley station, L. & S.W. Ry., on or before November 1 next. The bulbs will be grown under exactly similar conditions, and will be inspected by members of the Narcissus and Tulip Committee, who will recommend awards to the Council.

GERARDE'S HERBAL.—Lovers of old garden literature will rejoice to hear that Messrs. METHUEN, the well-known London publishers, are contemplating the reproduction of a facsimile copy of JOHN GERARDE'S *Herball or Generall Historie of Plantes*, which was first published in 1597. The undertaking is subject to the necessary support being forthcoming, and the names of subscribers are required before the work can be embarked upon. Messrs. METHUEN, it will be remembered, recently issued a reproduction of JOHN PARKINSON'S *Pardisi in Sole*, which has been so well received that the few remaining copies are only to be procured at a much higher price than that at which it was first supplied to subscribers. GERARDE'S *Herbal* is a work of far greater bulk, and therefore more costly to produce, and if a sufficient list of subscribers can be obtained it will be issued to them at £3 3s. net, which price will be raised to £4 4s. on the day of publication.

CO-OPERATIVE FLOWER, FRUIT AND VEGETABLE SHOW AT THE CRYSTAL PALACE.—On Saturday, August 26, the Annual Co-operative Flower, Fruit, and Vegetable Show will be held at the Crystal Palace. The schedule is a comprehensive one, and a good show is expected. Apart from the general list of prizes offered by the Society, special prizes are being

CAMPANULA MICHAUXIOIDES; FLOWERS PALE BLUE: HEIGHT 5—6 FEET.:
AS GROWN BY ARTHUR R. GOODWIN, ESQ.

offered by Messrs. SUTTON & SONS, the Agricultural and Horticultural Association, and others. Entry forms may be obtained from the Secretary, Flower Show, 22, Red Lion Square, London, W.C. The Agricultural Organisation Society is this year for the first time presenting a handsome Certificate of Merit to all winners of 1st prizes.

THE ROYAL BOTANIC.—We are asked to publish the following statement:—Mr. C. BRINSLEY MARLAY presents his compliments and begs to enclose the principal points of the statement he made at the special meeting held on June 23 at the Royal Botanic Gardens in order to introduce a resolution raising the subscription to Fellows and members from 2 to 3 guineas annually. He does this in case he made any mistakes in conducting the proceedings, as his position was one of some difficulty, in order also that the much larger body of Fellows, who were not present, may comprehend the reason of the proposal. An estimate of the average expenditure of the Society for the last seven years is enclosed, which places the matter clearly before the Fellows. The simple reason that the Finance Committee appointed by the Council, and of which Mr. MARLAY was Chairman, asks unanimously for this rise is that the subscription which when the Society was first formed sixty-five years ago was amply sufficient, is so no longer. This is not owing to the necessity of increased outlay, so much as to the rise in wages, materials, rent and taxation.

1. Wages of gardeners have risen from 15s. in 1839 to 25s. in 1905.
2. Taxes from £17 14s. 4d. to £409.
3. Price of materials nearly doubled.
4. Rent from the first lease, 1839, to the one granted in 1901, £285 to £450.

In addition to the large increase here stated, the Finance Committee had to consider seriously the necessity of a sinking fund in order to meet interest on and redemption of the debentures, which amount to £28,500. Hitherto there has been no provision for this purpose, which is absolutely necessary if the finances of the Society are to be placed on a sound basis. The financial statement which accompanies these notes show that without allowing for any reserve fund the annual deficit on an average of seven years is £222. If a reserve fund is added, of £822. Of course the question arises whether so large a sum as £600 is necessary to be placed to the reserve fund. It was the opinion of the Finance Committee that it was necessary. The ultimate decision on this and on other points will rest with the Fellows. Mr. MARLAY would add that the cost of public parks and gardens in London is said to have more than doubled during the last few years. The cost of gardening in London, it must not be forgotten, is far more expensive than in the country. It is essential that plants under glass should be continually washed, and outside plants syringed whenever it is possible to do so. Even heavy rain does not remove dirt and soot. This washing is a heavy expense, and many nurserymen are leaving the near neighbourhood of London, or hiring country ground in addition to a London establishment. The opponents to any change in the rate of subscription may say that this would not be necessary if the Gardens were developed and made more attractive. But this development has been going on for some time, and it is difficult to see what can be done without altering completely the character of the Gardens, and still further diminishing the privileges of the Fellows who really keep up the Gardens. The Society was in reality far better off when the Fellows possessed exclusive rights, and the public was not admitted without difficulty. It is impossible to calculate on the success of any entertainment in the open air as a source of income. The two last summer shows, owing in

great measure to the weather, resulted in considerable financial loss, although they were admirably arranged. The visitors on Bank Holiday do little more than pay for a good band. In conclusion it must not be forgotten that amongst the 2,000 Fellows of the Society the tastes are different—some want quiet, some amusements, some sports, others a playing-ground for their children. It is the duty of the Council to consider these wishes, and to meet them where they can. The ultimate decision rests with the Fellows; it is for them to decide when the legal period expires during which the resolution is hung up for their consideration whether the subscription should be raised or not. Mr. MARLAY is sure they will consider the question from all points of view; and he may add that any suggestions any Fellow may make, any proposal for the maintenance and improvement of the Society, will be given every facility of discussion and very carefully considered. There is no question of insolvency. The gardens, the houses, and plants are in better condition than they have been for a long time, and possess admirable features for those who only require a garden in the centre of London where rest and quiet may be found, birds may be heard to sing, and where the flowers which will grow in London, and they are more numerous than is generally known, display their beauty and give forth their fragrance. Mr. MARLAY begs any communications arising from the proposal to raise the subscription should be sent to the Secretary at the Gardens, Regent's Park.

MISSOURI BOTANICAL GARDEN.—The sixteenth Annual Report contains the report of the Director, Professor TRELEASE, on the working of the garden during the year 1904. The total number of persons who visited the gardens was 316,747, a number greatly exceeding that of any previous year. This increase was, of course, due to the large number of visitors to the St. Louis Exhibition—viz., 12,804,616—from which figures it is inferred that about one in ten of those who went to the exhibition also visited the garden. The authorities of Mill Hill School, near London, was educated, contributed a number of photographs illustrating the school. There were exhibited in connection with the portrait of the founder, and with various views in the gardens,

a full series of the publications illustrative of its progress during the fifteen years of its existence. Among the scientific papers which form the bulk of this volume is one by Mr. ALWIN BERGER, entitled a systematic revision of the genus *Cereus*. Mr. BERGER establishes no fewer than eighteen subgenera, but remarks that Cacti as well as other succulent plants can never be understood unless they can be studied from a large collection in a sub-tropical garden where they are grown in quantities in the open. From this point of view the author acknowledges his obligations to Sir THOMAS HANBURY. Twelve plates illustrate this useful monograph. Other memoirs are included, of which our limitations preclude further notice. We cannot, however, omit to mention the very remarkable paper on the dehiscence of anthers by apical pores in certain widely separate families, and on the co-relation between this peculiarity and the agency and geographical distribution of insects. A comparatively new field of observation and research is here opened out by Dr. J. A. HARRIS.

A BOOK ABOUT SALADS.—This little book by ALFRED BROADBENT, and published by him in Manchester, has a threefold object:—"To spread a knowledge of the beneficent properties possessed by roots and green vegetables; their preservation by appropriate methods of cookery, and to urge the need for more general cultivation in the home garden and elsewhere of many salad vegetables now so rarely grown." It is written from a rather one-sided point of view, and while agreeing that salads are wholesome we cannot follow the author in all his opinions. He might have given a much larger list of salad plants, broad-leaved Endive and several other favourites at home and abroad being omitted. It may be "extravagant" to throw away the water in which Onions or Cabbages have been boiled; but we think most people will find excellent reasons for not storing it.

PLANT-FOOD CONSTITUENTS USED BY BEARING FRUIT-TREES.—The New York Agricultural Experiment Station, in its Bulletin for April, 1905, publishes an elaborate report on this subject, from which we extract the following:—

The work was undertaken for the purpose of ascertaining the amount of nitrogen, phosphoric acid, potash, lime, and magnesia used in one growing season by bearing fruit-trees.

One to three standard varieties of each of the following kinds of fruit-trees were selected for the purpose: Apple, Peach, Pear, Plum, and Quince. The trees were typical representatives in the full vigour of bearing.

The fruit, leaves, and new growth of wood as represented by the tips of branches were carefully gathered, weighed, dried, and analysed in the case of each individual tree.

Tables are given showing the amount of each of the plant-food constituents in the different portions of each of the trees. The relations of the tabulated data presented are discussed in detail.

Peach-trees used the largest amounts of plant-food; Apple and Quince-trees, approximately alike in the results given, come second; while Pear and Plum-trees, which give results much alike, come third.

As to the relative proportions of plant-food constituents used, using 1 lb. of nitrogen as a basis for comparison, it was found that the different fruit-trees used very nearly the same relative proportions of the different plant-food constituents. The averages were as follows:—Nitrogen, 1 lb.; phosphoric acid, 0.27 lb.; potash, 1.14 lb.; lime, 1.35 lb.; magnesia, 0.45 lb.

THE NEW ZEALAND INTERNATIONAL EXHIBITION.—The Government of New Zealand has decided to hold during the summer of 1906-7 an International Exhibition at Christchurch, Canterbury, in which all the nations of the world are invited to participate. The object of the exhibition is educational, and it is intended to demonstrate the resources and possibilities of the colony as one of the world's food-producing factors, its vast mineral resources, and to draw attention to its unrivalled and varied scenery, thermal wonders, and also to the exceptional

opportunities offered to sportsmen. Further and especially it is desired to bring under the notice of the more industrial nations of the world the great field the colony of New Zealand offers as an outlet for enterprise, and for the use and consumption of all manner of up-to-date appliances, manufactures, &c. The scheme is a large as well as an important one. Applications for space, with full particulars, may be lodged with the Agent-General for New Zealand, Westminster Chambers, 13, Victoria Street, London, E.C.; or with the Secretary, New Zealand International Exhibition, Christchurch, New Zealand. Such applications should be made as soon as possible, and cannot be received after March, 1906.

NEW PLANTS FROM CHINA.—Messrs. JAMES VEITCH & SONS, of Chelsea, have published an illustrated list of new plants recently introduced from Central and Western China, and now ready for distribution. Several of these plants are of great interest and beauty, and many have been figured and described in the *Gardeners' Chronicle*, and we may add that with few exceptions all of them are hardy in Great Britain. Mr. Wilson's expeditions in search of novelties have abundantly disproved the notion that we had practically exhausted the supply of "new" plants.

KEW NOTES.

GESNERIA REGINÆ.—Several plants of this pretty and comparatively new species are now in flower in the Begonia-house. The habit of the plant is almost exactly that of a *Gloxinia*, both as regards its tuberous root and the foliage and flowers. The leaves are of a dark velvety green, the midrib and the main veins being silvery-white. They are about 8 inches in length and 5 inches in breadth, with a crenate margin. The flowers are very freely produced, being borne on a stem 4 inches high. They are a bluish-purple in colour, the corollatube being 2 inches in length and drooping, as in some *Gloxinias*.

It is a delightful plant, and may be easily propagated from leaves in the same manner as *Begonia Rex* is propagated. It requires stove treatment.

IXORA COCCINEA VAR. LUTEA.

A small batch of this distinct variety may be seen in the stove. It has been in cultivation since 1890, having been sent to Kew from the Botanical Gardens, Ceylon, in that year. It is rather more spreading in habit than the type; the apex of the leaf is more rounded, and the leaves are usually of a lighter green than those of the species. It is as free-flowered as any of the better known kinds. The inflorescences are from 4 to 6 inches in diameter, the individual flowers are rather more than 1 inch across and of good substance; the colour is a pale clear yellow. This is a beautiful variety, which is scarcely known in gardens, but one which should be more widely known and grown. *W. H.*

BRACHYSTELMA BARBERÆ.

Possibly for the first time in Europe, this remarkable South African plant may now be seen in flower at the Royal Botanic Gardens, Kew. In 1866 it was figured and described by Sir Joseph Hooker in the *Botanical Magazine* at t. 5607, from a drawing sent from South Africa by Mrs. Barber, but so far as known to me it has not been in cultivation before.

The plant has a large flat tuber, which produces a stem 2–3 inches high, bearing a few pairs of leaves, $\frac{3}{4}$ –3 inches long, $\frac{1}{2}$ –1 inch broad, varying from oblong to oblanceolate, acute or obtuse at the apex, tapering into the short petiole below, pubescent on both sides. The very curious flowers are very numerous, and arranged in a large globose cluster 3–4 inches in diameter

(formed of two opposite sessile umbels), surrounding and almost hiding the rest of the plant. Each flower has a short tube about $\frac{1}{2}$ inch long, marked inside with transverse, irregular purple-brown lines on a pale yellowish ground; the five lobes are narrowly linear or tail-like, spreading at the base, then ascending and incurved and united at the tips, forming a sort of elliptic cage $\frac{3}{4}$ –1 inch long and $\frac{3}{8}$ – $\frac{7}{8}$ inch in diameter, green outside and rich dark crimson-brown on the inner face, pubescent on both faces with hairs of the same respective colours.

The plant was originally discovered in the Transkei by Mrs. Barber, and has since been found in Tumbuland and the Transvaal. The odour of the flowers is carrion-like. *N. E. Brown*. [The tuber of this plant was collected by Mr. C. F. H. Monro in Rhodesia, who forwarded it to Kew amongst a collection of bulbous plants in May of this year.]

TRENT PARK.

ONLY a very few miles separate the Trent Park estate from the City of London, but the characteristics of the two places are as opposite as those of the poles. It is probable that many are unaware that within so short a distance as ten miles from "The Bank" there is a residence situated in such a spacious park that whether the visitor approaches it from this or that of the several lodges he must drive or walk one mile after passing the park gates before he can reach the dwelling-house. The present writer having recently had the opportunity to visit the place for the first time was as surprised as some of his readers may be at finding there similar conditions to those one has grown accustomed to associate only with residences in the more or less remote counties.

Trent Park is the residence of F. A. Bevan, Esq., a busy banker, who employs his leisure moments in philanthropic work, and in gardening. Chrysanthemum growers will doubtless remember his name in connection with the excellent exhibits of Japanese Chrysanthemum blooms that won first honours for Trent Park year after year at a time when Mr. John Leese had charge of these gardens. There is at the present time a collection of about 1,000 first-rate Chrysanthemums in pots, which show that these plants are still valued highly, though they may not constitute so predominant a feature in the garden as they did formerly.

The mention of these Chrysanthemums reminds us forcibly of the evidences the plants bore of injury sustained on Sunday, July 9, when a hail-storm of unusual fury visited the locality and broke many of the shoots, almost ruined the Apple and other hardy fruit crops, riddled many of the vegetables, and washed much of the gravel from the sloping paths and across parts of the lawn into the lake. A note on the effect of the same storm at Finchley and at Wrotham Park was published in our issue for July 15, p. 51. Many of our readers know only too well the extreme disappointment felt by the gardener when the results of his efforts suffer so severely from such an unpreventable cause at a season of the year when everything should be looking at its best! But we are digressing, for this note was intended to be an "impressionist" description of Trent Park gardens as it appeared during an exceedingly brief visit late on a July day, when the heat in the City was almost unendurable.

The drive from New Barnet station was very enjoyable and the scenery pleasant. On entering the park one could soon see that it possesses excellent timber, the trees appearing most prominently being of Beech, Oak, Lime, Hornbeam, Sycamore, and Holly. The ground is moderately undulating, and there is a double avenue of Lime-trees that is a distinct feature, although the trees have been pruned somewhat mysteriously at one period of their existence. We approached

the brick dwelling-house from the south side, being that shown in the illustration at fig. 46. There is no flower gardening on this side of the house at all, but the Oaks and Beech trees arrest the attention.

Passing round to the north side, the scene is quite a different one. There are terraces immediately in front of the house, and flights of seven stone steps leading therefrom. The ground slopes away rather steeply, and in front of the first wall, in place of a very steep slope of grass, four grass steps have been made recently. A considerable area in front of the terrace is enclosed by a low wall, which is relieved at frequent intervals with vases on the stone top. The centre of this enclosed area is of grass, and the flower garden is in the shape of borders under the wall on every side. These borders for the most part are planted with batches or groups of plants, or with plants forming a low ground cover, and taller ones interspersed among them. Such groups were of Saapdragons (*Antirrhinums*), *Verbena*, *Salvia splendens*, *Fuchsias* growing over a groundwork of dwarf *Lantanas*, *Lobelia cardinalis* over yellow-flowered *Violas*, *Salpiglossis*, *Pentstemons*, *Cannas*, *Stocks*, &c. These plants were not mixed, but were in groups adjoining each other, and sufficient of one sort as a rule for the eye to rest upon for the moment. It will be seen therefore that there is no formal bedding done at Trent Park. Near to these borders an oval or oblong bed was planted with *Verbena hybrida* "King of the Scarlets," the growths of which were pegged to the soil, and edged with *Gazanias*, while a few standard *Fuchsias* were flowering over the *Verbena*. This *Verbena* is very effective when so used, and at Trent Park another variety of *Verbena* is planted very largely. It is named F. A. Bevan, and when the flowers first open they are tinted with pink colour, passing afterwards to white. They are fragrant, and whether used as a pot plant or as a summer bedding plant, the variety, which was a seedling raised by the present head gardener, Mr. Henry Parr, is very much esteemed. An extensive stock of this plant has been raised. On this same side the dwelling-house is very prettily draped with climbing plants and creepers, such as *Roses*, *Ivies*, and *Ampelopsis*. Turner's *Crimson Rambler* is apparently 20 feet up, and grows and flowers very satisfactorily. Within the view from the terrace also could be seen several good specimens of *Yucca recurvifolia* in flower. Beyond the outer wall already mentioned the ground slopes sharply away down to the lake, a fine sheet of water covering an area of about 6 acres. The intervening lawn is planted with beds of flowering shrubs. The lake being at the base of the valley, the land rises on the other side just as sharply as on the dwelling-house side. Consequently the bank beyond the water can be seen very well from the terrace, and therefore steps have been taken to produce good effects there with flowering shrubs and other plants. At the top of the slope the view terminates in dense plantations, which should be opened out just a little in several places in order to add greater distance to the view.

We passed from the terrace to the south-east of the house, and in the direction of the lake, noting on our way a little rockery and water-garden with flourishing *Bamboos*, &c., screened in a manner that they come upon one with considerable suddenness.

At a point a little further on, the water from the upper to the lower lake falls over stones and makes pleasant music, a kindly seat close by offering a rest that the falling water may be listened to. But we had now reached the other side of the lake, and found there along the banks of the water a variety of ornamental plants, including yellow-stemmed and red-stemmed *Osiers*, golden *Elder*, double-flowered *Gorse*, *Pampas*

Grass, &c.; and higher up the bank beds of Kniphofias (Tritomas), Rhododendrons (Azaleas), and other things, all of which are effective as seen from the house. Further on towards the south-west corner a wild-garden or "dell" has been formed, with a stream running through it. This has been all done by the present gardener, and it affords a very pleasant addition to the garden's attractions. At the time of our visit the Roses were particularly beautiful, especially several polyantha varieties and Crimson Rambler. All

and transplanted every year not later than the middle of March, the ground being trenched and liberally manured each time. Apricot-trees on an outside wall facing to the west were already ripening a good crop of fruits. There are improvised fence-like supports covered with Roses in the kitchen-garden, and we were particularly attracted by a plant of the new variety (Rambler) Dorothy Perkins, which had been planted only two years, yet had covered a width equal to from 5 to 6 yards.

Malmaison, and "tree" or winter-flowering types (very fine), Codiaums, Caladiums, Cordylines, Coleus, Orchids, Azaleas, Lilliums, Hippeastrums (a large number), Gloire de Lorraine Begonia (cultivated very successfully), Clerodendron fallax, &c.

We should not omit to mention the Gooseberry plants trained just as Raspberry canes are trained, and the whole covered with netting to protect them from birds. Dessert Gooseberries grown in this manner are of the very best, and not only

FIG. 46.—VIEW OF TRENT PARK, NEW BARNET.

were supported with rough-looking wooden supports that answered the purpose very well, being less formal looking than would be welcome in the trimmer portions of the garden. The Nymphæas, Irises, Bulrushes, &c., were quite in keeping with the surroundings.

THE KITCHEN-GARDEN AND GLASSHOUSES.

There is a good kitchen-garden contained within walls, and the crops generally are in first-rate condition, apart from any injury caused by the storm. This garden is interesting and bright, for there are exceedingly good borders of herbaceous flowering plants on either side of the principal path and in other positions. In addition there is an unusually fine collection of Michaelmas Daisies (Asters), and a rich collection of some of the newest varieties of Cactus Dahlias, Pentstemons, &c. The Michaelmas Daisies are lifted

There are several good Peach-houses and vineries. One Peach-house containing three divisions, in which the variety Barrington was conspicuously good, is very noteworthy, because it would be next to impossible to see Peach trees in better condition than these, whether judged by the weight of crop, vigorous foliage, or well-trained trees.

In the vineries the variety Muscat of Alexandria is bearing long heavy bunches of fine berries, and young Vines planted last year have made unusually good growth. Melons are grown numerously and with much success. In a house 35 feet long by 8 feet high, the crop on one side alone amounted to 112 fruits, being one of the best crops we have ever seen.

There are numerous plant-houses and frames for raising fresh stock. The principal plants we noticed were Carnations of the Souvenir de la

will they hang for a long time in a ripe condition upon the plants, but they can be gathered with the utmost convenience.

The general condition of the gardens, indoors and out, is a credit to Mr. Parr, who has had charge of them for several years past.

Obituary.

A. TOOLEY.—Many gardeners who at one period or another were associated with the late D. T. Fish at Hardwicke Gardens, Bury St. Edmunds, will remember Mr. A. Tooley, who for upwards of forty years had been employed in those gardens. He was Mr. Fish's responsible man for some years, and was especially fond of Roses. Mr. Tooley died on July 19, after an illness which had lasted for four years.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

EXOTIC TIMBER TREES.—Your valued contributor, Mr. Molyneux, mentions in his note on the behaviour of various timber trees planted at Swanmore Park within the past thirty years, the Scots Fir, the Corsican and Black Austrian Pines, besides the common Spruce, and rightly ascribes the non-success attending the planting of them to the hard unbroken clayey subsoil. Such a mishap, so expensive and disappointing, might have been averted had test-holes been dug at various points over the area to be planted, which would have disclosed the nature of the land. This practice is always advisable in the case of new forest planting. Such land as is described is sure to favour water-logging, and may not be cured by trenching, always an expensive job that is scarcely ever rewarded by sufficiently good prices obtained perhaps a century later. It is more advisable to make "grips," i.e., open drains deep enough to drain off the water in the land to a safe depth, say 4 feet, keeping these clear by a scoop such as is used in laying pipe drains. These grips may be made in heavy soils at 30 feet apart, and in the direction of the natural fall of the land. If the proprietor does not object to the cost, and chalk, greensand, or stone is cheaply available, a layer 1 foot in thickness may be laid at the bottom of the drains, and the soil returned to them, choosing the top spit to cover the materials. I should not hesitate thus to relieve land of excess of water even after the planting is done. In the case of approaching "stagheading" in Oaks, itself a sign of a water-logged state of the soil, it is one of the best things to do to avert this mishap. It is not in the least surprising that trees of *Thuia gigantea* at 30 feet in height, therefore about as many years old, should be found productive of wood extremely soft and of little weight, as it is a fact that hardly any coniferous tree has hard (heart-wood or other) at so early an age. An exception is found in *Juniperus virginiana*. *F. Moore.*

ESPALIER-TRAINED TREES AND SPRING FROSTS.—In most gardens, and more especially in windy seaside districts and those not surrounded by high walls or hedges, and thick shelter belts or close woods behind these, Apples and Pears suffer greatly from frosty winds in the spring, and from the equinoctial gales in the autumn; and standards, bushes, and pyramids suffer in about equal degree. The loss of fruit blossom and of fruit is much lessened if, instead of these forms, espaliers planted in lines a few feet distant from the paths be grown. The trellis may consist of strained solid or twisted wire, ungalvanised by preference, or oaken stakes, or hop-poles cut to 8 feet in length, the lower 1½ foot being charred and tarred. If wire be employed, the wires may be fixed at 1 foot apart horizontally, as also may the stakes, vertically. In the early spring, after pruning and tying are finished, boards of half to three-quarters of an inch in thickness may be secured above the trees, over which bast mats, frigi-domo, or even double fish netting may be thrown when frosts appear to threaten. The manipulation of the shoots in the season of growth, as well as any desired thinning of the fruits, are matters easy of performance on espaliers, making such trees of great use in any garden. *F. M.*

ESPALIER-TRAINED APPLE-TREES.—For convenience in attending to the trees, for appearance also, for full cropping, and for rich colouring of the fruit, espalier-trained trees have much to recommend them. In a Yorkshire garden but a few miles from the city, where I once spent two years, many specimens of leading varieties of this form of Apple training succeeded right well. In Major Petre's garden near Norwich I saw growing upon espalier-trained trees the finest coloured examples of *Mere de Ménage* Apple I ever saw; in size too they were remarkable. Mr. Davison told me he invariably had a full crop of good fruit from the same trees. There is one word of caution I would give to those who contemplate planting this class of tree. Do not attempt to keep the trees too dwarf. Trees not more than 3 feet

6 inches high do not admit of sufficient space for growth development; the trees are apt to make too much growth at the top at the expense of cropping. I know of many instances where the espalier-trained trees were planted near the edge of garden-paths and kept low for the sake of appearance; but in a few years the trees were extended in an upward direction, which spoilt their previous character. This was done for the sake of an extra fruit crop, of course irrespective of appearance. Five feet or 5 feet 6 inches is a suitable height to train the trees, not only for a full fruit crop, but for convenience and appearance as well. *E. M.*

THE PEACH AS A STOCK FOR THE PLUM.—Soils are so various in this country, from heavy red loam to close retentive marl, I am afraid, the Plum would not prove very satisfactory if it were dependent on the delicate roots of the Peach, besides which, I think, the injury to the stock would develop canker. Some years ago a friend of mine who had emigrated to the Colonies, informed me that the Peach was used there as a stock for Plums and for Peaches and Nectarines, but the conditions of the soil and the winters were more favourable than they are here. Only in the warmer and more favoured parts of our island where there is little stagnant moisture in the soil during the winter months would there be any chance of success, and even then, I am afraid, the somewhat tender roots of the Peach would perish unless they were protected. A dwarfing stock for Plums would certainly be welcomed by all fruit growers, and the stocks in question may be worthy of trial at the Wisley gardens. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

THE FALLING OF ELM-LIMBS IN SUMMER (see p. 119).—An instance of this occurred here in a tree growing by the roadside, on the 30th of last month. A large bough, 1 foot in diameter, dropped without any warning, and with no wind whatever to assist the breaking. The limb snapped square across close to the trunk, and without any apparent reason, as the leaves are quite healthy and the branch devoid of dead twigs. I can only assume that it was the weight of the leaves that caused the fracture. *E. M., South Hants.*

RED CURRANTS.—*Vanitas vanitatum!* It is sad to learn how little we know, even of that of which experience should at least have taught us something, and it is often surprising what an extraordinary estimate some, happily few, individuals have of themselves. Critics would be more likely to be listened to if their pen were used somewhat less freely in depreciation of men and things. For my own part I believe it is the duty of everyone to give what knowledge he gains for the benefit of his fellow-men; and it is wholly and solely with this view that I write. It is now some sixty years since I was growing fruit for competition; previously I was often associated with those who were quite capable of teaching me. Some time afterwards I marketed much of my fruit at Covent Garden Market. Thus it is that I have been trained from time to time not only to test but to give my views as to the quality and worth of any new varieties that may be offered. I was led to grow the monster new Red Currant "Comet" by the representation of that most reliable nurseryman Mr. Amos Perry. Here is what he said, "This is the greatest acquisition for many years amongst fruits," &c., and he further adds that it is a remarkable fruit, and it had an Award of Merit of the Royal Horticultural Society. So I resolved to try it. But also I give the opinion of Messrs. Laxton: "For freedom and fruitfulness there is nothing to surpass this variety," and "altogether a sterling new variety." After growing Comet for three years I ventured in a much milder way to give my opinion as to its excellent qualities, as to what it proved in my peculiarly cold soil. This seems to have elicited the displeasure of my critic, for he asks that if it is worthy of note why Messrs. Veitch or Messrs. Bunyard do not catalogue it, and asserts that I had hastily jumped at the conclusion that it might be as Mr. Bunyard describes it, who says it is the same as

Fay's Prolific. As I have grown and discarded Fay's Prolific I at once say that I do not see any resemblance between them, nor am I in the least influenced by any such remarks. As to Star of the North, I may add that for many years I grew La Versailles as my main crop, and found it to be the most valuable, free-bearing, handsome variety; thus I feel qualified to controvert the assertion that they are one and the same. Of the Star of the North I have a number of bushes; I find it is an excellent bearer of long bunches of fruit, very early, and very sweet. Thus it is more attractive to birds than any other. I intend growing it as a first early, Comet as second, and the old Red Dutch as last. If I have another, which is doubtful, it will be La Versailles. The white sort of the latter is excellent. It is a matter of no importance to me what Mr. Bunyard has to say of Comet, for I have proved it myself; and further, as I was probably growing fruit before Mr. Bunyard was born, my opinion is entitled to some credit. Nor do I place undue reliance on what may be done at Wisley or elsewhere, for I am sufficiently old to know that what proves to be useful and good in one place may utterly fail in another. Had my critic said that Pears by their number of novelties were getting "mixed," I could have understood him, but with Currants the call for intervention is needless. In my remarks I jumped at no conclusion, but merely gave my views as to what the Currants were here, leaving entirely to others to plant any if they chose to do so. *Harrison Weir, F.R.H.S., Appledore, Kent.*

STOCK "BEAUTY OF NICE."—A few days ago I had the pleasure of inspecting 2 acres of this fine novelty in flower in the grounds of M. A. Adams, Esq., Gattens, Ockley, Essex. The plants are strong-growing, of good habit, and flower profusely. The individual flowers are very large, flesh-coloured, and sweetly scented. Mr. Adams obtained the seed of this excellent stock direct from Nice, in which place he saw it growing in all the gardens in and about the town, hence the name Beauty of Nice, and so far as Mr. Adams is able to judge he is the only one in England who grows it. The single-flowered plants, though lost sight of among the wealth of double flowers, are sufficient in number for seeding purposes, and their condition gives promise of a good seed harvest being secured both from the plants growing under glass and out-of-doors. In addition to the great number of Beauty of Nice Stock now in such grand flower at Gattens, there are large plantations of young plants both out-of-doors and under glass for continuing the floral display well into the winter. Mr. Adams flowered several thousand plants in some of his large glasshouses during the past few months. The plants are growing on benches 6 feet wide and 6 inches deep, running the entire length of the houses, three benches being in each house. *H. W. Ward, Rayleigh, Essex.*

THE FRUIT CROPS.—It was doubtless a coincidence that the annual reports as to the condition of the year's fruit crops, and the outline of the report of the Government Committee on the fruit-growing industry, should have been simultaneously published on the 29th ult. What a striking comment is presented by the fruit reports on the Committee's conclusions! Not all the Government Committees in the world can by reports remove the ill done to home fruit culture by the frosts of last spring. That they destroyed confidence in fruit production is but too evident. Rarely have we had a year where at once an abundant tree fruit crop was more due, in the cultivators' interests more needed, and of which there was at one period greater promise. How all these anticipations have been falsified, your reports on the year's fruit crop tells all too sadly. What is to be done to prevent similar calamities in the future? It must be remembered that in the general wreck of the crops the highest art in culture has suffered as much, and perhaps even more, than has the mere inferior or deficient art. The question of good or bad culture has really nothing to do with the results. The good and the bad have been taken equally, the former perhaps rather more. All the high culture in the world seems quite unable to affect climatic con-

ditions. May frosts as sharp as those of last May may come with appreciable regularity for generations, and as long as fruit-trees and fruit-bloom are what they are, the joint labours of Nature and men in obtaining a glorious bloom may be all in vain. It has been suggested by you that raisers of fruits should seek to create either a hardier or a later-blooming strain, that would offer no tender blossom to the biting frosts or blasts until all danger was past. This year we had our Plums and Pears in full bloom in April, the flowers had freely set, and fruit was abundantly formed ere the *coup de grâce* was given to it by the frosts of May. Apple-trees were in full bloom from the end of April till the end of May, but the

I have over 500 plants, and intend this autumn to plant over $\frac{1}{2}$ an acre, as I find this variety brings better prices than any other I grow. You will note the two rows of petals in it, also its habit, which is perfect in every way. The flowers are half as large again as those sent in a good season. I intend to call it C. m. "George Brooke." *George Brooke, Neville's Cross Nursery, Durham.* [The flowers were $3\frac{1}{2}$ inches in diameter. Ed.]

IS ROMNEYA COULTERI AN HERBACEOUS PLANT?—I note what your reporter says anent this plant as exhibited at the Cardiff Show as a hardy plant, but in a class from which shrubby plants and trees were excluded. With

more than fifty stems." The competition in all the Sweet Pea classes was exceedingly keen, as many as eighteen competitors taking part in some classes. It would be difficult to find a better display than there was under the unfettered conditions. The blooms were of high quality generally. Some few showed the effects of the weather, but most of them were bright and attractive, especially those from Mr. Thomas Jones, Ruabon. Under such conditions the judges had but to consider quality and arrangement, as well as nomenclature, of course. They were able to leave the arrangement of the flowers in the vases as they found them. The magnificent display of this popular flower nearly filled one huge tent. *E. Molyneux.*

Photograph by C. P. Raffill.

FIG. 47.—CLEMATIS INDIVISA, AS IT FLOWERED IN THE TEMPERATE HOUSE, ROYAL GARDENS, KEW.

gravest harm was not done to them until the mornings of May 22 and 23. Evidently to save fruit-tree bloom from such dangers only trees that opened their flowers in June might be expected to be safe from injury. Trees flowering so late could hardly even in the best of seasons mature fruit crops thoroughly during our all too short summers. But the possibility of ever getting so late blooming trees or varieties seems to be almost Utopian. Practically of all the varieties of tree fruits raised during the past 200 years, there seems to have been no appreciable tendency to produce specially late blooms. Even the oft-mentioned Court Pendu Plat Apple is no more fruitful this year than is any other variety. When the proposed Fruit Conference is held at Vincent Square, Westminster, in October next, it is hoped that no time will be wasted in talking customary fruit platitudes, but rather that its energies will be directed to the consideration of that crucial subject, "How to preserve our fruit-trees from injurious climatic conditions." *A. D.*

CHRYSANTHEMUM MAXIMUM.—I send you some flowers of a seedling Marguerite which I raised three years ago, but the flowers are not nearly so good this year owing to the drought.

me *Romneya Coulterii* does not die down to the ground. In Norfolk, in Lord Battersea's garden at Overstrand, there are bushes of it 6 feet high and as much through. In Devon I have seen it even larger, forming a full bush. Under such conditions, how should such a plant be classified? Another plant which has given similar trouble ere this is *Phygellus capensis*, which in some seasons does not come under the strict definition of a herbaceous plant, hence many judges have hesitated to disqualify or to accept it. *H.*

EXHIBITING SWEET PEAS.—As emphasising what I advocated a short time since in the *Gardeners' Chronicle* (see p. 52) about limiting the number of sprays in a bunch, the action taken by the Committee at the late Cardiff show is a good illustration. I recommended the Committee to ask for a certain number of bunches, and to allow exhibitors to stage as many sprays in each bunch as they chose, provided they are shown in the Society's vases. At Cardiff there are six classes for Sweet Peas in bunches; in five of them there is no limit to the number of sprays. In Mr. Sydenham's class there is a limit, but there the regulations are quite of an elastic nature. He says: "Not less than thirty nor

CLEMATIS INDIVISA.

We have illustrated the beauty and floriferousness of this tender *Clematis* on previous occasions, but Mr. Raffill's photograph (reproduced at fig. 47), showing a plant as it appeared in the spring of the present year in the temperate-house, Royal Gardens, Kew, is so charming, that we feel sure our readers will welcome it. There is little reason for us to say much about the plant, it being so well known as an excellent species for training on chains or on the rafters in a greenhouse, where it usually produces an abundant display of flowers in spring. It is not subject to many pests, but if the atmosphere of the house is somewhat damp for a considerable period and there is insufficient ventilation, the leaves are liable to become disfigured with mildew, and it is then necessary to apply flowers-of-sulphur. All who have not got this species and who possess suitable means for its cultivation, may be recommended to procure a plant.

REMARKS ON THE CONDITION OF
THE FRUIT CROPS.

(See Tables and General Summary, ante, pp. 81-87.)

(Continued from p. 117.)

3, ENGLAND, E.

CAMBRIDGESHIRE.—The severe frosts during the latter part of May practically ruined the fruit crop in this district. On May 26 we registered 10° of frost. Previous to that there was every indication of a good fruit year. *R. Alderman, Babraham Hall Gardens, Cambridge.*

ESSEX.—On the whole the fruit crop has been satisfactory. Young Apple-trees planted three and four years ago are yielding well, and promise to be very good. The crop of Pears is not so good as it promised to be when the trees were in bloom. The late frosts were probably responsible for the fruit dropping badly. Strawberries have been our worst crop; mildew attacking them soon after setting has caused many to rot. Our soil is cold and heavy, and the subsoil stiff clay. *A. Bullock, Copped Hall Gardens, Epping.*

— Once more May frosts have destroyed the promise of a fair crop of Apples, Plums and Pears for the year 1905, the crops of these fruits are almost nil. Gooseberries, Currants, Raspberries and Strawberries have been good average crops. The soil here is a light sandy loam resting mostly on a bed of clay—a fruit-tree growing soil in every sense of the word. *H. W. Ward, Lime House Nursery, Rayleigh.*

HUNTINGDONSHIRE.—Here on this black fen soil we have fair crops of most fruits except Black Currants, which are this year a complete failure. Stone fruits are excellent both in quantity and quality. Red and White Currants, also Raspberries, are very good, while Strawberries have been very good and plentiful. *F. W. Seabrook, Ramsey Abbey, Gardens.*

LINCOLNSHIRE.—In this district Apples and Pears are very scarce. Plums are an average crop, Victoria being the best variety. Cherries are average and of excellent colour. Peaches and Nectarines are very good. Apricots are up to average, and the fruits are of satisfactory size and good colour. Gooseberries, Red, White and Black Currants are good. Raspberries and Loganberries are very good, especially the variety Superlative. The soil is a strong clay subsoil, which accounts for good results in spite of the dry weather. *F. J. Fleming, Wellsby Old Hall Gardens, Grimsby.*

— All fruit trees blossomed abundantly, and appeared very promising until May 23, when the thermometer on the outside of a Stevenson screen fell to 25°, and on the grass to 19°; fortunately the sun shone very early or the effects generally would have been much worse. Pear-trees had what appeared to be a heavy crop, but the trees in the open quickly dropped their fruits. On wall-trees we have a good crop, but the Pear midge (*Diplosis pyrivora*) has again thinned them severely. Plums were also set before the frost occurred and there was a good crop, but large numbers fell after the frost. Apples were for the most part in full flower, and very few have escaped; it will be almost as poor a crop here as in 1903. Those which have survived are chiefly on the tops of tall standards and our latest-blooming variety Bess Pool. Bush trees have scarcely a fruit left upon them. Strawberries had very few flowers open when the frost came, and we have an abundant crop; other small fruits are also abundant. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

NORFOLK.—Most of the fruit-crops in this district are very poor, the failure being due to the very severe late spring frosts, and to a dry and generally unkind spring. The soil for the most part is of a very sandy and porous nature,

and the absence of rain and genial spring weather kept all growth very backward and weak. Possibly some part of the failure might be attributed to lack of vitality in the trees consequent upon general overcropping in 1904. As trees cannot recuperate so quickly on these soils as on those of a more fertile nature, unquestionably we ought to thin severely in a season of heavy crops, and where labour permits there is no excuse for not doing so. At the time of flowering nearly all trees showed promise of heavy crops. I have only seen moderately good crops in one or two places. Probably the frosts were not so severe in those places. *E. C. Parslow, Shadwell Court Gardens, Thetford.*

— In this district we suffered a great deal from the effects of late frosts. The early blossoms of "Early Laxton" and other Strawberries were all cut off by the frosts of May 22 and 23, which caused great damage to all kinds of small fruits. We are badly in want of rain. *J. W. Bradbrook, Kettingham Park Gardens, Wymondham.*

SUFFOLK.—Fruit-trees of all sorts were very promising in the early part of March, but towards the end of the month and in April and May cold east winds set in and caused great destruction. Peaches on walls suffered very much with "blister," owing to the cold winds, but notwithstanding have set, and are swelling an average crop of good fruits. Apples and Cherries are our worst crops in this district; some orchards have not a single fruit in them. Orchards all round this district are very old, and show signs of want of proper cultivation. Large fields of Strawberries and small fruits are planted in a well-sheltered valley in this district about 3 miles from the sea, and this year Strawberries have produced good crops. They are owned by small holders, and for want of proper railway facilities there is no outlet for the fruit, except to the seaside towns by hawking, so prices for good fruit are kept very low. Our soil is mixed, and rests on a gravel subsoil. *T. Simpson, Henham Hall Gardens, Wangford.*

4, MIDLAND COUNTIES.

BEDFORDSHIRE.—With a few exceptions the Apple and Plum crops in this district are a failure. There was but little bloom on Apple trees, due I think to the trees having exhausted themselves by carrying heavy crops last year. Pears gave every promise of being a good crop, but were severely thinned by the Pear midge. All bush fruits have produced record crops. The soil here is a very heavy loam with a gaulty subsoil. *H. Nimmo, Cranfield Court Gardens, Woburn Sands.*

— The soil here is sandy and gravelly, and most fruit-trees grow very fast when first planted, but fail as they get old owing to canker and American blight, caused, I think, by the manure and digging of the soil rendered necessary by the vegetables. *H. W. Nutt, Flitwick.*

— There was an abundant show of bloom on Pears and Apples, but the keen east winds and the severe frost on May 20 quite spoiled the fruit prospects in regard to trees growing in the open orchard. It is only on the wall-trees and in sheltered parts of the garden that the crops have escaped. Sweet Cherries are only a light crop on outside walls. The Loganberry is doing well here, and promises to be a useful addition for tarts and jam-making. The soil here is of a heavy nature, with subsoil of clay impregnated with iron. *T. W. Birkinshaw, Hatley Park Gardens, Sandy.*

— The fruit-blossoms suffered very much injury during the night of May 23, when our thermometer, placed 4 feet from the ground, registered 5° of frost. Before that date the Apple, Plum, and Strawberry crops were

very promising. The soil is a nice sandy loam on a subsoil of chalk and clay. *Geo. Mackinlay, Wrest Park Gardens, Amptill.*

BUCKINGHAMSHIRE.—The frosts experienced during May did immense injury to the fruit-crops on all sides. Apples are an average crop; Pears and Plums are very thin; Cherries are average, but owing to the wet weather we experienced in June many of the fruits of the sweet varieties split. Peaches and Nectarines are good, and the trees are clean. Figs promise to be a good crop. Strawberries have been abundant and of good flavour. Gooseberries and Black and Red Currants are an average crop, and the quality of the fruit is all that could be desired. *John Fleming, Wexham Park Gardens, Slough.*

— It is a most difficult matter to form anything like an accurate estimate of the fruit crops in this part of the county. The outlook during the early spring months was most favourable for hardy fruits, but the disastrous frosts at the end of May ruined the crops in low-lying districts. Especially was this the case in the Thames valley. In the immediate neighbourhood of these gardens, which have an altitude of about 270 ft. above the sea-level, there are some excellent crops of hardy fruit. Apples are very good on the Paradise stock where due attention was paid to thinning the fruits last season. Bush fruits are excellent, but Pears are very scanty. The Pear-midge effected more damage than the frosts. Plums are very good. Strawberries have been of poor flavour. *Chas. Page, Dropmore Gardens.*

— The fruit crops in this district are very irregular. There was a wealth of blossom, and every prospect of a good fruit season. The frosts of May 22 and 23, followed by easterly winds, and the long, continuous drought in May and at the beginning of June, were destructive. Apples are an average crop, and the varieties Lord Suffield, Ecklinville Seedling, Bramley's Seedling, and Adam's Pearmain are very good. Plums on trained trees are moderately good; Kirke's, Monarch, Reine Claude de Bavay, and Jefferson's are the best. Apricots are an average crop; the varieties Moorpark and Kaisha are good. Cherries on standard trees and on trees trained against walls have been abundant. Strawberries have been exceptionally good and of excellent quality. Red and Black Currants, Gooseberries, and Raspberries are plentiful. The soil here is very light and gravelly, on a subsoil of gravel and chalk. *G. W. Smith, The Gardens, Danesfield, Marlow.*

— The Apple crop is very irregular, and much under the average. Pears are a total failure. Although this district is noted for its stone fruits, this season Damsons, Prunes, and all kinds of Plums are failures, owing to late frosts. In some orchards the trees are badly infested with blight. Crops of small bush fruit are, on the whole, good. The early Strawberry bloom suffered by the frosts, and the crop has been fairly good, but the fruit undersized. What with the late cold spring and a wet, heavy soil, we are experiencing one of the poorest fruit years for many seasons past. *W. Hedley Warren, Aston Clinton Gardens, Tring.*

CHESHIRE.—The fruit crop, so far as Apples, Pears, and stone fruits are concerned, are rather disappointing, for after a most promising show of blossom the fruit failed to set, and even where it did set the fruit dropped. I attribute this to the abnormal crops of last year leaving the trees weak, as the weather was not at all unfavourable in this district. The soil is of light texture, but free from gravel. *Peter Wilkinson, Walton Lea Gardens, Warrington.*

— Most kinds of fruit trees blossomed profusely, but the crops are poor, excepting Morello Cherries, Currants, Gooseberries, and Straw-

berries. Of Strawberries the variety Fillbasket, which thrives well on our light sandy soil, has been specially good. The Loganberry has done well also, and at the time of writing looks quite picturesque with its abundance of large bold fruits. Pears, Apples, and Plums have been quite a failure. *E. Slater, Norton Priory Gardens, Runcorn.*

DERBYSHIRE.—A splendid set of fruit all round was spoiled by long-continued drought and north and north-east winds. The early promise was never better. Of Plums and Damsons there are practically none. Gooseberries are very good indeed. Morello Cherries are a very heavy crop throughout the neighbourhood. Peach and Nectarine trees suffered badly from the cold winds. On the hill there were no spring frosts severe enough to kill fruits and blossoms, but cold winds for weeks in succession were too much for the young fruits of Apples, Pears, and Plums. The soil here is heavy and poor. *J. C. Tallack, Shipley Hall Gardens, Derby.*

— The Apple crop here this season is rather a light one; the trees bloomed well and gave promise of a good crop, but the severe frosts we experienced towards the end of May were disastrous. Pears on walls are a good crop and are doing well. Plums are under the average but good. Cherries are a moderate crop. Small fruits such as Gooseberries, Raspberries, and Red Currants are plentiful and good. Strawberries were an average crop, though the fruit on the older plantations were rather small. The nature of the soil is light and stony, and requires much water and mulching during dry weather. *Jas. Tully, Osmaston Manor Gardens.*

HERTFORDSHIRE.—The fruit crops here generally are small. Of Apples and Plums there are scarcely any. Peaches are much under average. Strawberries, too, are under. There are satisfactory crops of Pears, Cherries, small fruits and nuts. The prospects early in the season were promising. There was a good show of bloom, but it did not set well through the unfavourable weather, and many that did set were destroyed by the severe frost on May 23. *Geo. Norman, Hatfield House Gardens.*

— The fruit crops in this neighbourhood are again disappointing, particularly as the bloom was exceptionally abundant. It suffered, however, much damage from the very unseasonable weather during the month of May. In a year of disappointments, the condition of the fruit crops is perhaps the greatest. *Arthur Dye, Tring Park Gardens, Tring.*

— The frost and unfavourable conditions of the weather here from May 20 and a week afterwards proved very disastrous to our fruit crops. The soil here is gravelly, resting on clay and chalk, the latter being found at a depth varying from 6 inches to 15 feet. Crops have in consequence suffered from drought. *W. Whitelaw, Batch Wood, St. Albans.*

LEICESTERSHIRE.—The Apples in this district are a complete failure, the only tree we have with a full crop is one of the variety "Lord Grosvenor." Pears on the walls are good in quality, but much under the average in quantity. Plums grown on a west aspect in the kitchen garden are a moderate crop. Plums on standard trees in orchards were severely damaged by the frosts; The Czar and Rivers' Early Prolific are bearing a full crop; Pond's Seedling and Prince Englebert are the only other varieties with a "sprinkling" of fruit. Peaches and Apricots, particularly the latter, are clean and good. Of small fruits, Raspberries are a full crop. Gooseberries, Red and Black Currants are much below the average. Strawberries were the worst crop we have ever had, there was only the tail end of the crop left to ripen. *Givon's Late*

Prolific is the only variety which escaped the frosts; to this variety too much praise cannot be given for its productiveness and quality. *Daniel Roberts, Prestwold Hall Gardens, Loughborough.*

NOTTINGHAMSHIRE.—Apple and Pear crops suffered severely through late frosts. Late Pears escaped and are bearing well. Black Currants completely failed through same cause. Trees of all kinds are clean and healthy. *James Gibson, Welbeck Gardens, Worksop.*

— There was a splendid show of blossom on all fruit trees, but they suffered badly from late frosts and cold north-easterly winds. The soil here is very light. We have suffered badly for want of rain until the recent rains set things up again. Fruit trees are all looking very healthy. *A. W. Culloch, Newstead Hall Gardens.*

OXFORDSHIRE.—The disastrous frosts in May and June did great damage to the fruit-crops along the vale at the base of the Chiltern Hills, and only where efficient protection was given was the crop partially saved. On the summit of these hills for a distance of 2 miles the fruit-crops are abundant. Cherries are an abundant crop, and fine clean fruit; many varieties of Plums likewise, Green Gage, a variety extensively grown, being the one failure. Apples likewise are swelling up good crops; while Gooseberries and Currants, both black and white, are an immense crop. *W. H. Clarke, Aston Rowant Gardens, Wallingford.*

— All bush fruits have done well, also Strawberries and Raspberries; but one dull, showery week when Strawberries were turning colour caused some damage to the fruit. Apple, Pear, and Plum-trees were a mass of bloom, but had no chance of forming fruit with the long spell of cold weather that prevailed, followed by a sharp frost on May 22. The soil here in South Oxford is poor, being very stony, over a subsoil chiefly of gravel or chalk. *A. J. Long, Wyfold Court Gardens, South Oxford.*

SHROPSHIRE.—As might have been expected after the abundant yield of last year, Apples are below average, and falling through the drought. Lord Suffield, Cox's Orange Pippin, Ribston Pippin, Tom Put, and Christie's Pippin are our best crops. Pears bloomed well, but suffered by frost, and are not at all good. Plums, Damsons, and other stone fruit are very patchy; in some districts there are none, and in others only a partial crop. Small fruits are a fair average crop. The soil here is generally of a light and porous nature on gravelly subsoil. *A. S. Kemp, Broadway, Shifnal.*

— The Apple and Pear crops appeared very promising in the early spring, but the blossom did not set well, and most of it fell. I was not surprised at this, owing to the heavy crops borne last year. I am afraid there will be many empty cider barrels, but we must preserve them, and live in hope. *Thomas Canning, Aldenham Park Gardens.*

STAFFORDSHIRE.—We had a splendid promise of all kinds of fruit up to May 22 and 23, when we had 8° and 10° of frost, which killed all the bloom. Bush fruit stood fairly well, as there was plenty of foliage. *C. A. Bayford, Shugborough Gardens, Stafford.*

— Hardy fruit crops in this district are in most instances much below the average, small fruits, such as Currants and Raspberries, being the only exceptions. A continuation of dull weather, with E.N.E. winds while the Pears and Plums were blooming, the scarcity of pollen and the absence of bees, I think account for the failure of these fruits; while the sharp frosts on the mornings of May 22 and 23, when the Apple trees were in full bloom, practically destroyed the Apple crop and killed the early

blossoms of the Strawberries. Our soil is very stiff, with a cold, clayey subsoil. Our rainfall for six months ending June 30 was only 8.45 inches. *Geo. Woodgate, Rolleston Hall Gardens, Burton-on-Trent.*

— The fruit crops generally are well up to the average. We suffered slightly from the frosts of May 21 and 22, which affected the early Strawberry blooms, also those of Pears. Of small fruits there is a quantity of Red and White Currants and Raspberries, but Black Currants are not so good. There is a fair crop of stone fruits, especially Plums, which appear to be swelling away well. *E. Gilman, Ingestre Hall Gardens, Stafford.*

— The Apple, Pear, and Plum trees were very full of bloom, but owing to late spring frost, Pear and Plum blossom did not set well. Apples set moderately well. The most prolific varieties in this district are Keswick, Lord Grosvenor, Lane's Prince Albert, and Beebench, a local variety, which the residents about here value highly. Strawberries and Raspberries are very heavy crops, but the fruits are rather small in size owing to dry weather. Black Currants suffer in the same way. *John Wallis, Woore.*

WARWICKSHIRE.—Had I filled up the tabulated form according to the circumstances of my own fruit crops I should have written four "no crops," and not as I did write, viz., four "unders." But on driving round this neighbourhood I find there is a sprinkling of Apples, Pears, and some Walnuts, and some Plums; these are to be found on trees which were situate well above the zone of the cold wave of May 21 and 22, which wrought so much mischief in this district. Therefore as a district reporter I thought by writing "under" I should give the better and more truthful representation of our fruit position; neither could I add "good, bad, or indifferent." We are still suffering from drought, and it would be rather hazardous to say which way these few fruits that are left will finish up. This year's experience following so soon on the heels of preceding years' disasters is further proof, if that were needed, of the fickleness of our climate, preventing us from ever anticipating any great success from the culture of either the Apple or the Pear in this country. On one side of my property we have the lower red sandstone and marl; on the other sandstone and red marl; but singularly I am between the two, with white sandstone, red marl and waterstones, the surface of which is a healthy brown loam, which will grow anything provided spring frosts would but keep away. *W. Miller, Berkswell.*

(To be continued.)

PETWORTH PARK, SUSSEX.

THIS fine old place, the seat of the Earl of Leonfield, possesses one of the largest parks in England, with a fine herd of deer, and some of the most extensive gardens and grounds. It is of the gardens I am now writing. In large places like Petworth everything must be produced in vast quantities to meet the requirements of the establishment, and credit is due to Mr. Edward Pull, the head gardener, for the excellent order and high standard at which these gardens are kept, many improvements having taken place during the years he has had charge. The old glass-houses have nearly all been pulled down and new and modern ones built, whilst new fruit-rooms and a fine packing-shed are amongst late additions to the place.

The Vines have been planted by Mr. Pull, and are all bearing fine crops of fruit; whilst Peach-trees are also carrying excellent crops. These gardens possess one of the oldest, if not the oldest, Fig-tree in the country, and it occupies one whole house. Melons were represented at the time of my visit by two houses of fine fruit;

as also were Cucumbers. One large house is devoted to Palms and suitable plants for house decoration, whilst two other houses are filled with Orchids, chiefly Cattleyas. *Calanthe Veitchii* and hybrids are extensively grown, there being nearly 200 fine specimens, which will render a good account of themselves when the autumn parties take place. *Chrysanthemums* are grown in vast quantities for supplying flowers for cutting purposes. Strawberries are forced to the extent of 2,000 plants, Royal Sovereign being the favourite variety.

Tree Carnations are well grown, some 400 fine plants being noticed. Amongst other subjects grown in large batches at Petworth are *Poinsettias*, zonal *Pelargoniums* for flowering in winter, *Begonia Gloire de Lorraine*, *B. Gloire de Sceaux*, and a fine batch of *Schizanthus wisetonensis* was particularly noticeable.

The kitchen-garden, which is divided into sections by walls, is very extensive, and the walls are covered with an up-to-date collection of hardy fruit-trees, perfect examples of good training. All crops looked promising, and abundant supplies of vegetables were to be seen in different stages of growth. The pleasure-grounds are extensive, and possess some of the giants of the country in the way of ornamental trees; the old Cork-tree, *Quercus Suber*, is certainly one of the oldest of its kind on these islands. Flower gardening is carried out extensively, and thousands of *Pelargoniums*, *Heliotropes*, *Calceolarias*, *Verbenas*, &c., are required annually for this purpose.

There is also a Cranberry-bed, not usually seen in gardens, and Mr. Pull informed me that the plants always bear heavy crops, and are much appreciated. *A. C. Smith, Lydhurst.*

SOCIETIES.

THE ROYAL HORTICULTURAL Scientific Committee.

AUGUST 1.—Present: Dr. M. T. Masters, F.R.S. (in the Chair), Rev. W. Wilks, Professor Boulger, Messrs. Douglas, Saunders, Massee, Drury, Worsdell, Holmes, Worsley, Sutton, Odell, and Chittenden (Hon. Secretary).

Mites on Furze.—Mr. SAUNDERS said: "The mites on Furze sent by Mr. Holmes, which were found so abundantly at Malvern, are one of the many species of *Tetranychus*, or red-spider, and are probably *T. lintearius*, as this species has been found to spin webs over Gorse bushes in the way described by Mr. Holmes."

Disease on Mulberry Leaves.—Dr. COOKE reported: "The spots on Mulberry leaves are strongly suggestive of *Cercospora moricola*, Cooke (see *Journal of the Royal Horticultural Society*, p. 30, pl. xii., fig. 29), but no hyphae or conidia could be found."

Eggs of Moths on Flowers.—Miss ALDAM, of Warmworth, Doncaster, sent flowers of *Pelargonium* on which masses of eggs had been deposited. Mr. SAUNDERS reported: "The eggs are those of a moth belonging to the family *Noctuidae*, and are very probably those of the common *Y. moth* (*Plusia gamma*), but the eggs of several members of this family are so much alike that I cannot say for certain. It is unusual for moths to lay their eggs on flowers, as the latter usually wither before the eggs are hatched; but many moths lay large numbers of eggs together on the leaves or stems of plants."

Insects on Apple-trees.—Mr. SAUNDERS also reported on insects from Apple-trees sent by the Countess of LEITRIM. "The only creatures which were in any way injurious were the caterpillars of the vapour-moth and the frog-hopper; the spiders and the long-legged 'Harvest-men' are not only harmless but beneficial in gardens, as they prey on other insects. The caterpillars of the vapour-moth (*Orgyia antiqua*) feed on a large variety of shrubs and trees. The caterpillars being hairy are not so easily killed by spraying as many are, but their food may be made distasteful or poisonous to them by spraying with paraffin emulsion or 'Paris-green.' The latter substance is poisonous, and it should not be employed within a month of the fruit being used for food. The

caterpillars should, if possible, be picked off by hand. The frog-hopper belongs to the family *Cercopidae*. I should not imagine that they are in such abundance as to be of any real injury to the trees. The 'Harvest-men' are curious-looking creatures, having such small bodies and long legs. They belong to a family (the *Phalangidae*) which are classed between the spiders proper and the scorpions. They are perfectly harmless to plants and human beings, and feed on aphides and other small insects. The small spiders which spin webs are also very useful in killing various small winged insects."

Fungus on roots of trees.—Mrs. Ashton, of Robertsbridge, Sussex, on digging up two Peach trees which suffered from silver leaf, found their roots were covered with fungus. A fungus also appeared on the floor of a tool-house which backed against the orchard-house where the Peach tree grew. Dr. COOKE wrote: "Probably the fungus under the tool-house and that on the tree roots is the same. It is evident there is a large amount of fungus in the soil, proceeding probably from dead roots or decaying wood. No trees can thrive with this in the soil. If possible a deep trench should be dug between the tool-house floor and the orchard-house to cut the connection, and lime should be used freely. The soil should be well dug up about the fruit trees, and the source of the root fungus found. Anyhow, the soil must be cleared of the white fungus mycelium, or all the trees will ultimately be killed. The soil must be well drained, as the fungus thrives best in stagnant water. In France it has been found effective to expose and powder the roots of trees which are attacked liberally with powdered sulphur. Thorough and severe steps taken at once may save much future trouble and expense."

Pears Cracked and Scabbed.—Dr. BONAVIA sent Pears from a young tree of Conference, which were badly cracked owing to the attacks of the fungus *Fusicladium pirinum* (see *Journal of the Royal Horticultural Society*, xviii. (1903), 14).

Lilium giganteum Rotting.—A shoot of *Lilium giganteum* which had rotted off completely near the point when about 18 inches high, was received from Mansfield. It was thought that in all probability this was due to the presence of excessive moisture.

Interesting Orchids.—Mr. F. W. MOORE sent from Glasnevin two species of *Megaclinium* having a curious flattened rachis on which the flowers were borne in two rows, one along the middle of each of the flat faces. From Sir TREVOR LAWRENCE came specimens of *Nephelaphyllum pulchrum*, a native of Java, which has been long in cultivation, but is rarely seen, and of *Theodorea gomezoides*, a native of Brazil.

Longevity of Seeds.—As an illustration of this point, Mr. WILKS stated that for the past twenty-six years a garden rubbish-heap had stood in a small wood near his house, and during that time only Stinging Nettles had grown upon it. The Stinging Nettles had this year been uprooted and the heap levelled, and now wherever the soil had been placed large numbers of Opium Poppies, *Papaver somniferum*, had sprung up, together with one plant of Borage. The only explanation possible was that the Poppy seeds had remained dormant for the past twenty-six years. Mr. DRURY remarked that a similar thing had occurred when some soil had been taken from under a house which had been built quite 100 years. Wherever the soil was spread, there the Poppies sprung up. Other members related similar occurrences, in each case *Papaver somniferum* being the plant that appeared. Mr. HOLMES mentioned an instance where *Hyoscyamus niger* grew under similar circumstances.

Harvest Bugs.—Mr. WILKS asked how harvest bugs might be combated. It was recommended to bathe the affected parts with salt water. Ammonia kills the bugs, while lard or grease alleviates the pain for a time.

Sports of Pteris aquilina.—Mr. DRURY showed photographs of fronds of *Pteris aquilina* gathered at Pitlochry. The fronds were very congested, crested at the ends, and somewhat crispate. The plant from which they were taken was growing in very stony ground.

British Plants.—Mr. HOLMES showed a prolific specimen of the common Toad Rush, *Juncus bufonius*, and some plants of *Matricaria discoidea*, an introduced plant.

Yellow-flowered Potato.—Mr. SUTTON showed a portion of a Potato-plant bearing yellow or orange-coloured flowers, with the following notes: "As you

are aware, the flowers of Potato-plants are either white or some shade of lilac or purple, and until last year I do not think that an orange-coloured Potato-flower had been seen or recorded. The history of the plant from which the accompanying specimen was taken is as follows:—When inspecting a 20-acre field of the Up-to-Date Potatoes last year in Lincolnshire we noticed an orange-coloured flower, which in the distance appeared to be a yellow Nettle, but on closer examination it proved to be a Potato flower. So far as we could possibly tell the plant was quite typical of the Up-to-Date variety, except in the colour of the flower. The whole field was carefully examined, and no other yellow or orange-coloured flower could be found. When the crop was lifted the tubers seemed to resemble the Up-to-Date Potato in all respects. Last spring we planted nine of the tubers taken from these plants, and in every case the plants have produced orange-coloured flowers, and the foliage in all respects resembles that of the Up-to-Date Potato. The normal colour of the Up-to-Date flower is of a rather dark lilac shade." The petals were thickened along the edge, and were in some cases becoming staminioid, bearing pollen on the margins.

Ornithogalum Ecklonis, &c.—Mr. WORSLEY remarked that the foliage of the plant shown by him at the last meeting differed from that of the plant as cultivated at Kew in having a pale green stripe running down the middle of the upper surface of the leaf. Mr. WORSLEY also showed some sprays of *Tropaeolum pentaphyllum* in full flower, gathered from a plant 9 feet high, grown at Isleworth. He remarked that as the flowers fade they turn green. He also showed specimens of a semi-double *Canna*, and drew attention to the fact that bees were seen paying considerable attention to the leaves of *Wistaria*, which had on the under surface a considerable amount of a sticky fluid. There were numbers of aphides on these leaves.

REMARKS.—Tomatoes have fallen considerably in price, owing to the arrival of large quantities, both foreign and English. Ripe Bananas will be scarcer towards the end of this week, owing to the majority of stuff arriving green. Cucumbers are a very bad trade indeed, owing to the large arrivals of Dutch crates. Nectarines are very plentiful of the small size, but best stuff is worth a good price; the same with Peaches. The "Claret" Bananas are expected to arrive shortly, nothing certain as to quantity or time of arrival. English Apples are fairly good, quantities are increasing daily. Trade generally very quiet. *E. H. Rides, Covent Garden.*

COVENT GARDEN FLOWER MARKET.

TRADE during the past week has been duller than at any period of the year, many growers are not sending anything, and those who do find it difficult to sell what they have. In flowering plants *Lilium lancifolium rubrum* is considerably overdone, and there is little trade for other *Liliums*. *Verbenas* and *Heliotrope* are also considerably in excess of the demand. *Zonal Pelargoniums* continue over-plentiful, and there are still some very good show and Ivy-leaved varieties. *Marguerites* are not so plentiful. Some moderately good *Fuchsias* are still seen, but most of the plants are not of the first quality. *Campanulas* are still over-plentiful; *Cannas* do not last well. *Ferns* are not so numerous just now as several growers are not sending consignments, but the supplies are fully equal to all demands. Small *Ferns* sell fairly well, but there is very little trade for the larger plants. Some very good *Codiaeums* (*Crotons*) are seen. There is a little demand for these for country trade. *Aspidistras* are more plentiful, and they are a little cheaper, but as the plants do not suffer much injury if they are left over, they are never cleared out very cheaply. A good many hardy shrubs are now coming in, but there will be very little trade for any pot plants until the middle of September.

CUT FLOWERS.

Supplies are over plentiful. *Roses* are generally very inferior in quality, but some of the blooms are good. *Carnations* are good; it is the American varieties that are the most useful. We now get good blooms of these all the year through. The flowers may not be quite so large just now, but they have long stiff stems, and are useful. Our very best border varieties do not compare favourably with these for the reason that they do not stand erect so well. *Chrysanthemums* are more numerous, but the best quality blooms still keep up in price. *Asters* and *Liliums* are over-plentiful. Some good *Montbretias* are seen. *Lily of the Valley*, *Gardenias*, *Tuberoses*, and *Stephanotis* continue to be plentiful. Some good *Orchids* are seen, and though not over-abundant, they are equal to all demands. *Chrysanthemum leucanthemum* and some of the improved varieties of the "Shasta" *Daisies* are plentiful. *Gladioli* are seen all round the market, and are sold very cheaply. All kinds of ornamental foliage is plentiful, and at closing time this morning much remained unsold. *A. H., Wednesday, August 9.*

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Vegetables: Potatoes, 2s. 9d. to 5s. per cwt.; Turnips, 6d. to 8d. per dozen bundles; Swedes, 3s. to 3s. 3d. per cwt.; Carrots, 6d. to 8d. per dozen bunches; Cucumbers, 1s. 9d. to 3s. per dozen; Onions, foreign, 1s. 6d. to 3s. per bag; Parsley, 6d. to 9d. per dozen bunches; Lettuces, 6d. to 8d. per hamper; Beans, 1s. 6d. to 2s. do.; Kidney, 5d. to 10d. per peck; Scarlet Runners, 8d. to 10d. do.—Fruit: Lemons, 11s. to 25s. per package; Oranges, 9s. to 15s. do.; Melons, 10s. to 15s. do.; Apples, Oporto, 7s. to 9s. do.; Grapes, Almeria, 5s. to 9s. do.; Bananas, Canary, 7s. to 9s. 6d. do.

EDINBURGH.—Grapes, English, 1s. 6d. per lb.; do. foreign, Denia, green, 8s. 6d. per barrel; do. black, 10s. 6d. to 12s. 6d. do.; Lemons, 28s. per case; Apples, Lisbon, 12s. 6d. per case; Nuts, Brazilian, 35s. to 35s. 6d. per bag; Melons, 11s. to 15s. per case; Bananas, 5s. 6d. to 10s. per bunch; Figs, 9s. per dozen; Tomatoes, Scotch, 5d. to 8d. per lb.; do. Guernsey, 4d. to 5d. do.; Onions, Egyptian, 4s. per cwt.; do. Valencia, 5s. 6d. to 6s. 6d. per box; Carrots, 1s. per dozen; Gooseberries, 3s. 9d. to 4s. 6d. per half sieve.

DUBLIN.—Cabbages, 7s. to 17s. per load; Cauliflowers, 2s. to 2s. 6d. per basket; Parsley, 2s. 6d. to 7s. per bag; Parsnips, 10d. to 1s. per dozen; Turnips, white, 4d. to 10d. per bunch; Scallions (young Onions), 4d. to 4½d. per bundle; Salad 6d. to 1s. per dozen; Thyme, 4d. to 5d. per bunch; Carrots, 7d. to 8d. per dozen; Potatoes, 4s. 6d. to 4s. 8d. per cwt. and 5s. for top lots.

GARDENING APPOINTMENTS.

- MR. A. SHAKELTON, late Gardener to Miss DUNCOMBE, Hadow House, Uckfield, Sussex, and formerly at The Grange, Nawton, York, as Gardener to Lieut.-Col. GUNDRY, Grange, Honiton, Devon.
- MR. GEORGE NELSON, for the past six years Gardener to the late R. E. LL. RICHARDS, Esq., Caer-y-nwch, Dolgelly, North Wales, as Gardener to Viscount NEWPORT, Castle Bromwich Hall, near Birmingham.
- MR. IRWIN HUGHES, late in the gardens at Waddesdon Manor, and previously Foreman at Birt Castle, as Gardener to Sir EDWARD W. BLACKETT, Bart., Matten Hall, Corbridge-on-Tyne.
- MR. ARTHUR HOARE, late Gardener to General BERESFORD, Rugby Lodge, Rugby, as Gardener to R. L. BARCLAY, Esq., Frogmore Lodge, St. Albans.
- MR. F. WICKENS, late Inside Foreman at Franks Hall, Farningham, Kent, as Gardener to Sir HCRACE MARSHALL, The Chimney, Streatham, S.W.

THE WEATHER.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Wisley, Surrey. Height above sea-level 150 feet. The following are the "mean" readings for the week ending August 5, 1905.

1905.	TEMPERATURE OF THE AIR.				TEMPERATURE ON GRASS.			TEMPERATURE OF THE SOIL AT 9 A.M.		RAINFALL.	BUNSHINE.
	At 9 A.M.	DAY.	WET Bulb.	NIIGHT.	LOWEST	At 1-foot deep.	At 2-foot deep.	At 4-foot deep.			
JULY 30 TO AUGUST 5.	Dry Bulb.	Wet Bulb.	Highest.	Lowest.	LOWEST	At 1-foot deep.	At 2-foot deep.	At 4-foot deep.	INS.	HR.	MIN.
MEANS	62	57	70	54	49	65	65	63	Tot 0.56	7	56

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending August 5, is furnished from the Meteorological Office:— "The weather was at first fine and dry over England, but showery in Ireland and Scotland. After Tuesday rain extended from the westward over the entire kingdom, and for the remainder of the week the weather was exceedingly unsettled, with heavy rain in the western and northern districts. Thunder was heard at a few isolated stations in England and Ireland on Tuesday, and thunderstorms occurred over Lancashire and North Wales on Thursday, in several parts of Scotland on Friday, and in the East and South-east of England on Saturday.

"The temperature differed but little from the normal. Over the country generally it was slightly below the normal, but in Scotland, E., and Ireland, S., it agreed precisely with the average, while in England, N.E. and E., and the Channel Islands there was a trifling excess. The highest readings, which occurred at times varying greatly in the different localities, ranged from 77° in England, S., and 75° in England, E., and the Midland Counties, to 67° in Ireland, N., and to 64° in Scotland, N. The lowest readings, which also occurred on various dates, ranged from 37° in England, S.W. (at Llangammar, Wells), and 40° in the Midland Counties and England, S., to 46° in England, N.E., and to 55° in the Channel Islands.

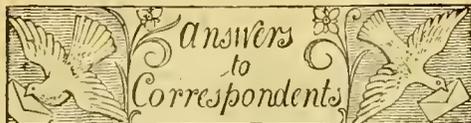

"The rainfall was in excess of the mean in most districts, but was either equal to or slightly less than the mean in England, N.E. and E. Between the 2nd and 4th heavy local falls were reported at many places in the west and north.

"The bright sunshine exceeded the mean in all districts excepting England, S., and the Channel Islands; in Ireland and in England, N.E., the excess was large. The percentage of the possible duration ranged from 49 in England, N.E., and 46 in England, E., and the Channel Islands, to 39 in Scotland, E., and England, N.W., and to only 25 in Scotland, N."

THE WEATHER IN WEST HERTS.

One very cold night.—During the past week there occurred but one unseasonably warm day, and even then the temperature in the thermometer-screen did not exceed 72°. On the other hand all the nights but one proved warm. On the one cold night, however, the thermometer exposed on the lawn fell to within 6° of the freezing-point—a very low reading for so early in the month. Both at 2 feet and 1 foot deep the ground is at the present time slightly warmer than is reasonable. Some rain fell on four days of the week, but the total measurement was not much more than half-an-inch. These rains have not been sufficient to affect even the bare soil percolation gauge, through which no measurable quantity has passed for nearly a month, although each day a few drops still continue to trickle through it during the twenty-four hours. The sun shone on an average for nearly six hours a day, or for about ten minutes a day less than a reasonable duration. On two days moderately high winds were recorded, the highest mean velocity for any hour reaching 16 miles on each of those days—direction south; but during the rest of the week calms and light airs prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon was as much as 8 per cent. in excess of the average quantity for that hour at the beginning of August. *E. M., Berkhamsted, August 9, 1905.*

[For actual temperature and condition of barometer at time of going to Press, see p. 133.]

BEAN: *J. T.* The Bean you send is that named and figured in the English edition of Vilmorin's *Vegetable Garden* as the Grey Zebra Runner Kidney Bean. It has also been called Luna and American. It is not considered suitable to our climate.

BEGONIA: *H. J. M.* The leaves are attacked with a minute insect, called the Begonia-mite. Dip the shoots in tobacco-water.

BEGONIAS: *Loughborough.* You do not say whether all your plants or only some show the variegated foliage. It is, of course, the result of the absence of the green colouring matter (chlorophyll), but why this has happened we do not know.

BOOKS ON TREES, &c.: *A. B. C.* You will find what you want in Schlich's *Manual of Forestry*, vol. i. (Bradbury, Agnew & Co.). We are not sure, but we think the volumes can be had separately. The *Uses of Plants*, by G. S. Boulger (Roper & Drowley, Ludgate Hill), or *Commercial Botany of the Nineteenth Century*, by J. R. Jackson (Cassell & Co.), contain some of the information you require. You might also consult the *Guide to the Museums of Economic Botany*, to be had on application to the Curator of the Royal Gardens, Kew, at a low price.

CARNATION: *H. C.* Evidently the work of some insect. We cannot say which one. Keep a sharp look-out, especially at night.—*A. C. L.* A good border Carnation, but it is impossible for us to name it. You might send it to a Carnation specialist. It may be an unnamed seedling.

CUCUMBER LEAVES: *S. F.* A bad case of Melon and Cucumber "spot." The best methods of treatment have been given in recent issues, and its cure by means of sulphur was described by Mr. H. W. Ward on p. 96.

FIG-LEAF: *Mac.* The leaf is very badly infested with red-spider, and this pest has caused the discolouration. It is unfortunate that you have to cultivate Fig trees in a vinery, and at the warmer end, because they require very copious syringings at all times, except just when the Figs are ripening. They are very liable to attacks of red-spider, which good cultivators try to prevent by pruning the trees in such a manner that they will not become crowded with growths; also by refraining from using more fire-heat than is necessary, by applying as much ventilation as the condition of the weather permits, by copiously syringing the trees twice each day when the sun is bright, and the fruits are not actually ripening, and by maintaining a considerable degree of moisture in the atmosphere by night as well as by day.

FRUIT-TREES IN POTS: *J. F.* The Apple, Pear, and Plum trees would succeed in pots or tubs of the size you mention (20 inches in diameter and 13 inches deep), providing that they are given suitable treatment. You must bear in mind, however, that fruit trees when grown in this manner require very much more attention and skilled treatment than they would need if cultivated in the open ground. If you are an amateur with little or no experience in the matter, you had better procure a copy of *Fruit Trees in Pots*, by Josh. Brace, from our Publishing Department, price 5s. 3d. post-free. We suppose you have no garden suitable for the trees? If you have there is little purpose to be served by having them in pots unless you intend to cultivate the trees for some period of the year at least in a glass-house. We have only space to state further that your trees for pot culture should be worked upon dwarfing stocks, such as the Paradise Quince, &c, and if you do not know how to prune the trees get some competent person to give you a practical lesson in the work. Your tubs or pots must be well drained.

FUCHSIA PLUGS: *C. A. P.* Probably some error in watering is the reason for the flowers falling prematurely.

GRAPES: *Vitis.* The remedy consists in keeping the conditions of the house, such as the degree, atmospheric temperature, and moisture as uniform as possible, and in supplying the roots with a proper degree of moisture, that they may not suffer from drought at one time and excess of water at another. Growth will then be continuous and normal.

HONEY: *W. D.* You should advertise for what you want. It is of no interest to our readers to print such questions in the Editorial columns.

MELON-ROOT: *Aston T.* A bad case of eelworms at the root. Burn the plants, turn out the soil, and supply fresh soil that has been baked or otherwise sterilised. Your order has been handed to the Publisher.

NAMES OF FRUITS: *W. B.* We think the Grape is a moderate sample of the variety Gros Colmar, but owing to the berries being much under ripe and to the fact that they were crushed during transit through improper packing it is not possible to be certain.—*G. Nottage.* Peach, Crimson Galande.—*J. E.* Plum, Early Favourite, raised by Mr. Rivers at the same time as Early Rivers.

NAMES OF PLANTS: *J. C. & S.* *Salvia Horminum.*—*Japonica.* *Cattleya granulosa* and *Oncidium prae-textum.*—*Mac.* *Begonia* "President Carnot."—*W. T., Gloucester.* *Dendrobium crystallinum.* It is often collected with *D. Bensonae*, and in the short-bulbed form is not easy to distinguish from it when not in flower, though usually the pseudo-bulbs are much longer and more slender than those of *D. Bensonae*. The flowers had withered, but the peculiar anther-cap renders identification easy.—*Swenstone.* 1, *Trachelium cœruleum*; 2, *Lysimachia*; we found no Carnation.—*Shrub.* 1, *Thuya nootkatensis*; 2, *Pyrus Aria*, White Beam; 3, *Cupressus Lawsoniana* variety; 4, *Leucothoe spinulosa*. We do not think the tying-up of the shrubs you mention had anything to do with their death. A certain proportion might be expected to suffer from transplanting.—*Croydonian.* Your plant is an *Ornithogalum* of some sort, but the material you send is not sufficient for us to identify the species. Why address the publisher on such a matter?

A. Y. L. The blue flower is not an Orchid, it is *Ophiopogon Jaburan*. The Orchids next week.—*W. D.* You have tied scraps of thin paper round the specimens, which scraps are difficult to remove, and are soaked with moisture from the plants—worse than all, you have not numbered them. The white flower is *Lysimachia clethroides*, the small blue flower is *Anchusa italica*, the large blue flower is *Gentiana asclepiadea*; then there is a *Valerian*, and the pale lilac flower with hairy leaves is *Phacelia tanacetifolia*.—*H. W. G.* So far as we can tell, the leaf is that of *Ailanthus glandulosa*.—*F. C.* *Rhus typhina*.—*T. M. N., Cape Colony.* 1, *Lastrea trichodes* of gardens; 2, *Asplenium dimorphum*; 3, *A. bulbiferum bifforme*; 4, *Adiantum Waltoni*; 5, *A. cuneatum mundulum*; 6, *A. cuneatum elegans*; 7, *A. cuneatum* variety.

ONIONS: *D. R. D.* The bulbs are affected with the Onion-mildew (*Peronospora Schleideni*). Use a free application of flowers-of-sulphur, and do not cultivate Onions on the same ground again for several years to come.

PEACH: *A. B. R.* The splitting of the stone is difficult to account for. In the first place the stone is not properly formed, then fungus has got in, and the fruit has fallen. Some adverse condition during the stoning period has caused the mischief, but what we cannot say.

PEAS: *An Old Reader.* The Peas are attacked by the Pea-mildew, *Erysiphe Martii*. Spray the plants twice a week with a solution of potassium sulphide, 2 oz. dissolved in 3 gallons of water. Some varieties are much more susceptible than others to attacks of this disease.

OWNERSHIP OF STOCK IN A NURSERY: *One in Doubt.* If the gardener or foreman brought the original stock to the nursery, and made no arrangement with his employer by which such stock should remain his own or partly his own

property, then the employer would be able to claim it, notwithstanding that the man had propagated and increased the stock without receiving orders from his master, and without his master's knowledge. The reason is that, although the original stock was never purchased by the master, it has been maintained and increased in the master's time and with his materials, and presumably by labour for which the master has had to pay. A servant should make an arrangement with his employer before doing such work.

PEACHES: *A. B. D.* You do not say at what stage of growth the fruits fall? We suspect that the two trees you describe as fruiting badly are growing too vigorously, and the cutting back of the growths with a knife will only make matters worse. If you believe them to be making shoots that are abnormally strong let the trees be lifted in October, and the roots be pruned a little.

PEARS: *T. H. S.* The so-called Pear-"fruit" is really a swelling of the flower-stalk, the true fruit being the core, which is embedded in the fleshy stalk. In your case the core is not formed. Such instances are not uncommon, and have often been illustrated in the *Gardeners' Chronicle*. If you were a cute American you would "boom" them as specimens of a coreless Pear. We do not advise you to do this, as we expect the enterprise would not pay! They are botanical curiosities only.

PREPARING GRASS-LAND FOR ONIONS. *Constant Reader.* Apply powdered lime at the rate of 20 cwt. per acre before the grass is disturbed, and when rain is expected; it will then get well washed into the haunts of vermin of all kinds, of which it is a good preventive and cure. It is also an important fertiliser, combining with other chemical elements in the soil and rendering them available food for plants. The folding and feeding of sheep is a simple and effective way of enriching the soil, and should be followed by deep cultivation, of which trenching is the best means, adding plenty of farmyard manure, and burying it at least 6 inches deep. This should be done if possible two months before the time of sowing the seeds. The influence of the weather will then sweeten and mellow the soil. To produce bulbs of the best appearance and longest keeping qualities, seeds sown in the spring are better than autumn-sown seeds. If they are sown during February in boxes placed in an atmosphere of an intermediate temperature, and the seedlings afterwards transplanted, a considerable advantage is gained. Soot is an excellent manure for Onions at any season, and nitrate of soda may be applied with advantage when the bulbs are forming; but care must be exercised in its use, about 1½ lb. to 50 square yards may be applied with safety. See also note under "The Kitchen Garden," on p. 129.

TOMATO: *Lec.* From your letter we gather that the plants have been afforded soil that is too rich in manures, or that you have applied liquid or artificial manures in excess of the requirements of the plants. You are perfectly right in supposing that the cutting away of great sappy leaves is extravagant, for it is sheer waste of the energies of the plants. At the same time, if your plants have made such enormous leaves and these are shading the fruits more than is good for them, you may shorten the leaves by pinching the ends from them. Another time let the plants be put into porous soil of only moderate richness, and make the soil very firm about the roots, which will cause growth to be made more slowly, and less long-jointed. Do not afford manures of any kind until the plants have set some fruits, but afterwards the requirements of the crop will prevent the plants becoming unduly gross. Procure a copy of *Tomato-culture for Amateurs*, by B. C. Ravenscroft, price 1s. 2d. post-free, from our Publishing Department.

BURNHAM BEECHES.

IN September, 1737, Thomas Gray, the poet, who, by the way, became at a later date a painstaking student of Linnaean botany, wrote to his friend Horace Walpole from his uncle's house at Burnham, where he was spending part of his vacation. "I have," he says, "at the distance of half a mile through a green lane, a forest (the vulgar call it a common) all my own—at least as good as so, for I spy no human thing in it but myself. It is a little chaos of mountains and precipices; mountains, it is true, that do not ascend much above the clouds, nor are the declivities quite so amazing as Dover cliff, but just such hills as people who love their necks as well as I do may venture to climb, and crags that give the eye as much pleasure as if they were more dangerous. Both vale and hill are covered with most venerable Beeches and other very reverend vegetables that, like most other ancient people, are always dreaming out their old stories to the winds. . . . The timorous hare and sportive squirrel gambol around me, like Adam in Paradise before he had an Eve; but I think he did not use to read Virgil, as I commonly do there."

The beauty-spot which the poet thus discovered to the world has many interesting associations. We read of an abbey founded at Burnham in the thirteenth century by Richard, Earl of Cornwall, the brother of Henry III., who only just missed becoming Emperor; but we are not aware of any vestige of monastic buildings now remaining. In the reign of Elizabeth the

Abbey lands were held on lease by Paul Wentworth, whose name was destined a little later to play a prominent part in English history; whilst it was during the tenancy of Lord Grenville, First Lord of the Treasury, some two centuries later, that the world-famed Pinetum was commenced in the adjoining domain of Dropmore. It was to East Burnham Cottage that Richard Brinsley Sheridan brought his beautiful bride, who had been Miss Linley; and in 1838 this house was bought by George Grote. Here he planned and mainly wrote his *History of Greece*, building with the profits the house he named History Hut, in which its completion was celebrated at Christmas, 1855, by the brewing of a bowl of punch; and here the historian was visited by Hallam, Cornwall Lewis, De Tocqueville, Bunsen, and others. In these days it is the residence of one as famous in horticulture as Grote in literature.

It is, however, for its natural beauties, and not for its associations, that we value Burnham Beeches to-day; and it was as a little oasis of pristine forest charm in the midst of a commonplace neighbourhood, and at no great distance from the metropolis, that the Corporation of London purchased 374 acres of it in 1879 for £6,000. Assuredly it was money well spent, and the public are much indebted to Mr. Francis George Heath, who persuaded the City to make the purchase, and has added to our obligation to him by preparing a valuable guide-book to this forest in miniature. The pollarded Beeches—the work, it is said, of Cromwell's soldiers—20 feet or more in girth at 3 feet from the ground, excel in their picturesque distortion the finest specimens of High Beech or Monk's Wood in Epping Forest; while the lawn by which they stand recalls the glories of the New Forest. Silent pools of dark water present beauties which none of the ponds of Epping can rival; the silver stems of slender Birches are reflected in their surfaces; fine tapering Hollies border a wide stretch of open heath; and with doubtful fitness the bloom of many Rhododendrons, planted before the Corporation took possession, mingle with sombre Yews in the denser groves of young Beech and Oak. A view of these picturesque trees was given in our number for April 9, 1904.

Traversed, no doubt, by too many roads with unnecessarily conspicuous sign-posts, this peaceful remnant of ancient woodland is sufficiently remote from railways and the busy haunts of men to retain much of the attraction that endeared it to Gray. B.

SOME RESULTS OF THE SEED HARVEST.

THE seed harvest season has been one of the most favourable in late years. On light lands the crops have been rushed owing to the drought, and there has been a danger of Broad Beans being affected by the smother-fly, but on the whole they seem to promise well.

Peas.—As has been the case in recent years, garden Peas will form an interesting item. Early varieties, now generally harvested, are disappointing in England, and the yield is light. The New Zealand crops of the early dwarf sorts are also below the average, but as these are not so much grown as formerly there will probably be enough. In some of the districts in Germany some of the crops of early Peas were almost entirely destroyed by hail when ready to harvest. At the moment

of writing the later varieties show a great shortage on account of the continued drought, the blight having attacked the late pods. There is evidence also of damage in the way of worm-eaten Peas, so that Pea-picking will be again a serious item of expense. Early buyers will be the most fortunate.

Beans.—Broad and long-pod promise well and should be plentiful, but it is not too late for the blight to appear. Runner Beans now in bloom promise well, but in Germany the acreage is very small indeed. Dwarf French Beans promise well, and should be reasonable in price.

Cabbages.—Cabbages are yielding well, but as the supply of the fancy sorts, such as Ellam's and Wheeler's, is practically exhausted, there will be ample room for all that will be saved. Cattle Cabbage is plentiful, and there is seed of last-year in most warehouses. French crops of Cabbage are very small, but there was a heavy yield last year, sufficient perhaps for two seasons. The Dutch growers also had good crops, but generally speaking the Continental varieties are not such as affect the English trade.

1,000-Headed Kale, so much in demand for feeding purposes, is of a much smaller acreage than usual this season.

Broccoli.—These are chiefly grown in Essex. All the crops have done well, and there is likely to be a good supply of seeds of most sorts.

Savoy Cabbages.—That popular variety Green Curled promises to be short in yield, and prices are a little advanced. Other sorts promise an average crop, as do all the Kales. Prices will remain at about the usual level.

Onions.—This will be the most interesting crop this season, and seeds are expected to realise very high prices. One main and perhaps principal reason for this scarcity is that the bulbs last season were worth so much money that instead of being planted for seed they were sold on the market. Added to the short acreage of home-grown seed, hailstorms have done enormous damage to the crops in Germany, and in California there is not more than two-thirds of the usual acreage. Altogether things look very unsatisfactory indeed, and as there is no seed in stock some growers anticipate that the cheaper sorts, such as White Spanish, will be worth as much as 5s. per lb. before the season is over.

Leeks.—After two or three years of plentiful harvests the seed crop promises to be very short, and the yield is already being bought up.

Radish.—The promise of the crops is found to vary considerably in the leading producing districts. In some parts of Germany the yield promises to be very good, but the crops in Anjou up to the present are disappointing. English crops of Radish require rain.

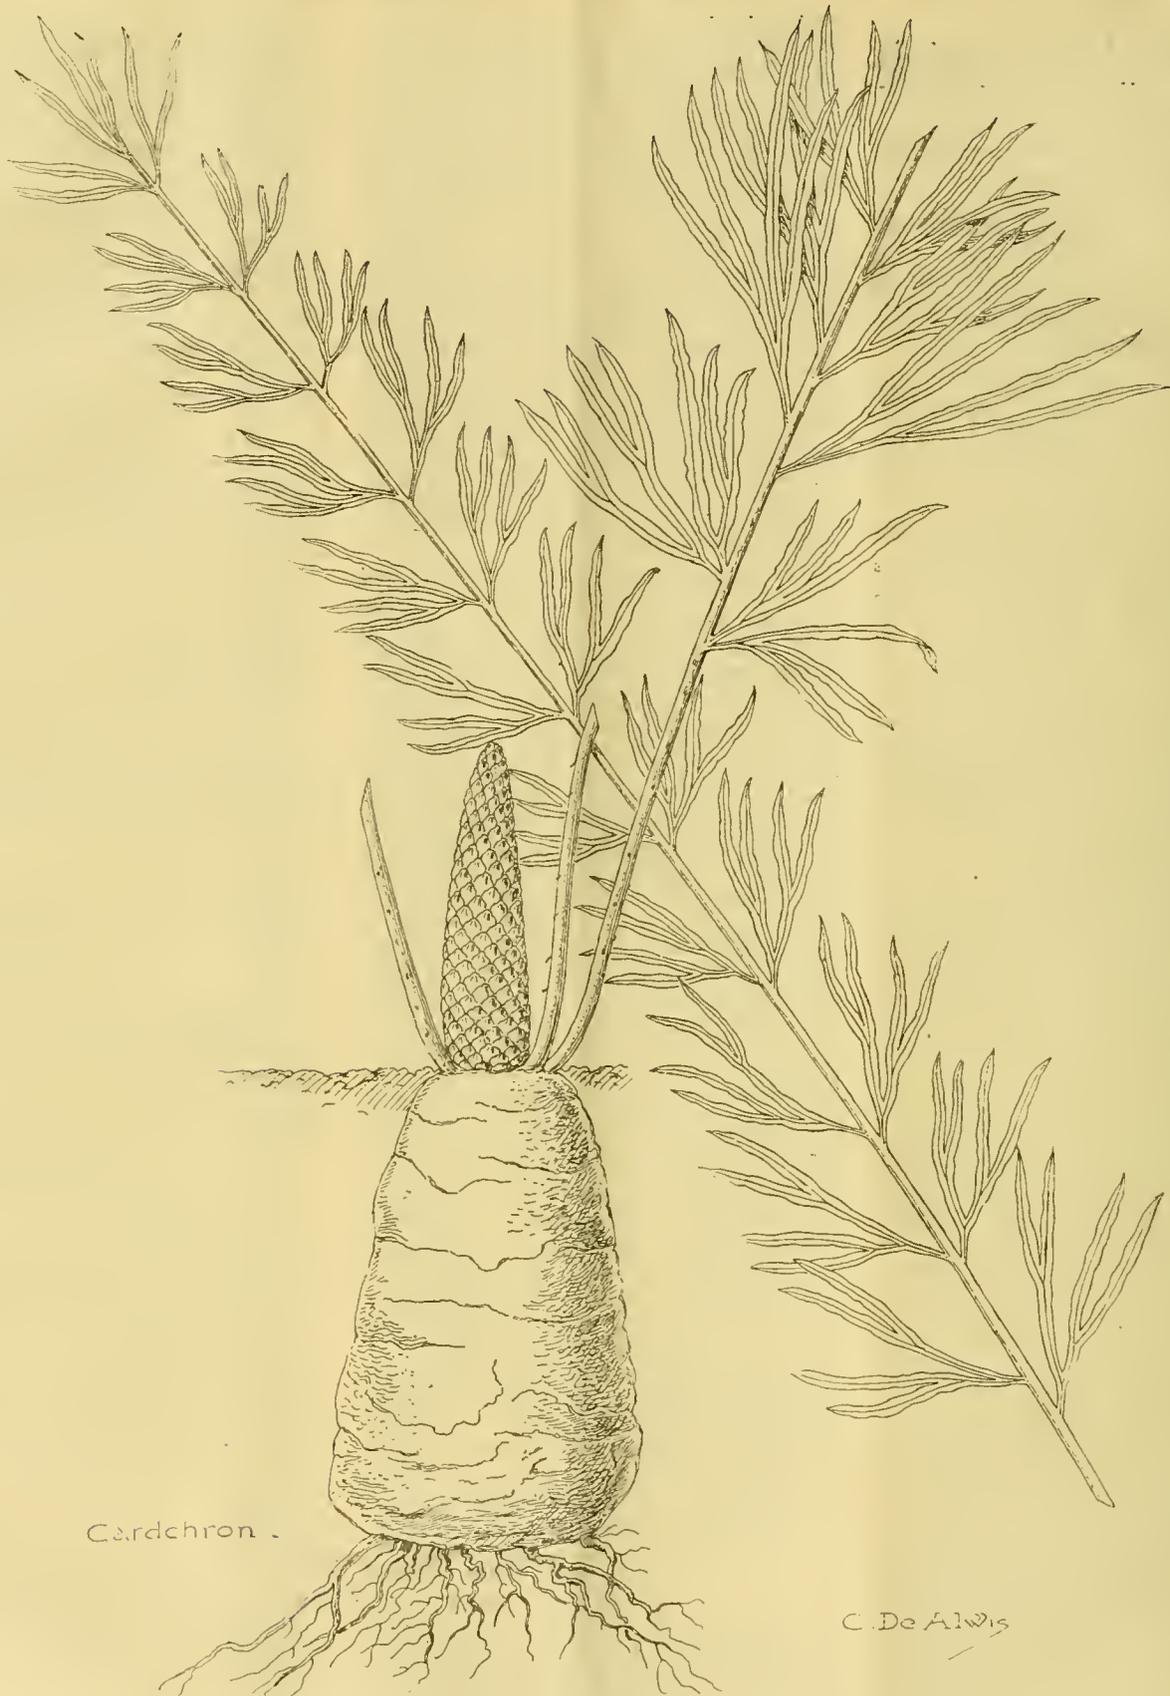

Cress.—This promises fairly well, and there should be good samples if the present weather continues.

Carrot.—The yield in Germany is expected to be very short, but there are highly promising crops in the south of France, while they are fair in Anjou, and are better nearer Paris. White Belgian Carrot will probably bear an advance in price.

Lettuce.—Both the Cos and Cabbage varieties promise excellent yields, and the harvest should be again a plentiful one.

Parsley.—Home crops promise an excellent yield, but less seed than usual is likely to be forthcoming from the Continent.

Summary.—On the whole, the crops promise a fair supply. Onions and Leeks will be the scarcest articles, Peas are generally worm-eaten, and the crops short. A great deal depends, however, on the actual damage done by the exceedingly heavy hailstorms in the seed-growing districts of Germany. Pisum.

Cardchron.

FIG. 48.—CYCAS MICHOLITZII, *Dyer*: ENTIRE PLANT.
Male plant with cone, showing also subterranean caudex and a leaf. (*Much reduced.*)

NEW OR NOTEWORTHY PLANTS.

CYCAS MICHOLITZII, DYER.*

I AM afraid the pressure of other work has compelled me to defer too long the formal de-

* *Cycas Micholitzii*, sp. n. Caudex subterraneus, $1\frac{1}{2}$ ped. longus $1\frac{1}{2}$ poll. crassus. Folia pauca, ad 10 ped. longa, basi ad $\frac{1}{4}$ ped. aculeis armata, pinnulis 8 poll. longis, fere 2 dichotomis, segmentis $\frac{1}{2}$ poll. latis.

scription of a new and very remarkable species of *Cycas* which Mr. F. Sander has placed in my hands.

We owe this interesting discovery to Mr. W. Micholitz, Messrs. Sander & Sons' collector, who had the good fortune to find the plant in Annam.

Strobilus mas (juvenilis) ad 6 poll. longus, squamis atheriferis brevissime acuminatis. Carpophylli lamina terminalis obovato-rhombæa superne profunde pectinata 3-lacera, Annam. Legit C. Micholitz. W. T. Thisleton-Dyer.

Complete material for its study came last year into the possession of my friend Mr. Ridley, the accomplished and enthusiastic Director of the Botanic Gardens, Singapore. The new species is so unlike any other *Cycas* in its foliage that it is scarcely a matter of surprise that Mr. Ridley proposed to make it the type of a new genus. In this however, for reasons to be presently explained, I found myself unable to concur; and Mr. Ridley, learning that I was interested in it

FIG. 49.—CYCAS MICHOLITZII, Dyer: DETAILS OF FOLIAGE AND MALE CONE.

A—Male cone (probably immature).

B—Lower surface of scale of male cone, showing anthers.

C—Upper surface of scale of male cone, showing anthers.

D—Carpophyll with immature fruits.

E—Pinnules half natural size.

very kindly placed all his material at my disposal. I am further indebted to him for the drawings by the artist attached to his staff, which are here reproduced.

A glance at these will show that the striking and remarkable feature of the new species is the

repeated dichotomy of the leaf-pinnules. If we except the Australian *Bowenia*, which in its "loosely bipinnate" foliage stands alone in the order, we might have affirmed till within the last quarter of a century that pinnate or pinnatifid leaves were uniformly characteristic of the

Cycadeæ. This conclusion was, however, rudely dissipated when the late Charles Moore published, in 1883, his description of *Macrozamia heteromera*, which has, unlike the rest of the genus, the pinnules once or even twice dichotomous.

One was scarcely, however, prepared for any-

thing of the same kind in the genus *Cycas*, which is widely distributed from Africa to Polynesia with numerous species, more or less well defined, but all having simply pinnate leaves. The first exception was a plant from Kwangsi, collected by Mr. H. B. Morse, which I described in the *Index Floræ Sinensis* (*Journal of the Linnean Society*, vol. xxvi., pp. 559, 560) as *Cycas Rumphii* var. *bifida*. In this the pinnules were simply bifid to the base. In the absence of any material of the reproductive organs, I regarded it, and I think most probably wrongly, as a mere variety of *C. Rumphii*. I was encouraged in this view by Miquel's figure of *Cycas inermis* (*Annal. Bot. Ind.*, ii., t. iii.), in which the lower pinnules of the leaf are represented as bifid. As Kwangsi and Annam are contiguous, it is by no means improbable that Morse's and Micholitz's plants may turn out to be the same. In that case the affinity of the former would be wholly remote from *C. Rumphii*, to which I referred it.

Cycas Micholitzii, as I propose to name the new species, belongs to the small group which is confined to an area extending from Nepal to Cochin China, in which the margins of the carpophylls are pectinate or comb-like. It differs from both the other species, *C. pectinata* and *C. siamensis*, in having a very short or obsolete acumen to the antheriferous scales, instead of the long and slender one which they possess.

According to the description of Micholitz, *C. Micholitzii* has a subterranean caudex or stem. Both *C. pectinata* and *C. siamensis* develop a trunk which may be 6 feet or more. *W. T. Thiselton-Dyer*.

FRUIT-TREE BUDDING.

BUDDING is more generally practised than grafting when propagating new varieties of fruit-trees because it entails less labour and produces equally good results, and furthermore enables more trees to be raised from a given shoot; for to be successful with grafting two or more eyes are necessary to form a graft.

Budding is generally practised during the months of July and August, the proper condition of the stock being the first consideration. This state obtains when the stock is growing freely, and when the bark is in such a condition that it is easily separated to allow of the insertion of the bud. If the stock is in a stunted condition and has already finished growing, it will be of little use to try and insert a bud under such conditions, so tightly does the bark adhere to the wood. Where this is found to be the case it is best to give the stock a good soaking of water. This operation can easily be performed with a limited number of plants; but in places where, as in nurseries, large quantities of trees are budded, the watering becomes a serious item; but I have nevertheless seen it carried out with success, and it has well repaid the trouble and expense taken. In some instances stocks will be found whose bark will not "run"—a term used when the bark does not separate freely from the wood. Such stocks should be left until the spring, and then grafted.

Usually the first subject ready for budding is the Cherry, followed by Apricots and Plums. The wood of the Peach and Nectarine is not in a suitable condition until late in the season, consequently these trees should be left until the last, the Pear and Apple preceding them. In selecting shoots from which the buds are to be taken, be careful that they are neither too hard and dry nor too soft and sappy. Generally speaking, a shoot which is just finishing its growth will be found to be in the right condition, that is, it should feel firm and stiff when bent between the finger and the thumb. Spindly, willowy shoots are useless, and medium-sized ones should be selected in preference to those of coarse growth. Weakly, ill-developed shoots whose buds

are not plump and prominent must likewise be rejected as unsuitable. Buds for the purpose are much better cut from trees growing in the open rather than from those growing against walls or under glass. This particularly applies to Peaches and Nectarines.

In commencing the operation of budding it is very necessary that the shoots should be freshly cut, and it is a bad practice to immerse them in water for too long a period, for by so doing the inner bark becomes discoloured, and the buds are consequently rendered useless. Buds that have travelled some distance and have become shrivelled may have their plumpness restored by laying them in damp moss. Young stocks varying from a $\frac{1}{4}$ to $\frac{1}{2}$ an inch in diameter are the best for budding purposes; old and aged shoots should be grafted. The scion from which the buds are to be taken should approach as near to the size of the stock as possible, and as the sizes of the latter will vary when a quantity have to be operated on, the diameter of the bud can easily be varied to suit the individual case by the manner in which it is removed from the scion. When the stock is made ready by removing any side growths that are in the way of the operator, a cross cut should be made one-third round the stock, and then a longitudinal cut $1\frac{1}{2}$ inch in length at right angles to the first, the two forming a letter T. The flat end of the budding-knife should be inserted between these cuts, and the rind lightly and carefully raised ready for receiving the bud. The leaves should be removed from the shoot containing the buds to be inserted, with the exception of about $\frac{3}{4}$ inch of the leaf-stalk. The shoot should be held with the growing point downwards, and the bud carefully removed with a sharp knife, severing the wood and bark with the included bud for about 2 inches. The wood should next be removed, a proceeding that requires great care. To do this expeditiously the bud should be held by the shield between the finger and thumb of the left hand, and the wood extracted with the forefinger and thumb of the right hand. When the wood is removed the bud is ready for inserting into the stock.

The process of tying-in the bud is an important item, and should be commenced at the lower part of the incision, leaving a sufficient piece of raffia to fasten at the top. It is important that the bud be securely bound below the shield, and again close down to the bud, so that the eye may be lightly pressed on to the wood of the stock. In from ten days to a fortnight it will be seen if the budding has been successful. Much depends upon the nature of the stock used as to what height from the ground-level the budding should be performed.

CHERRIES can be successfully budded on the Cherry-stock at any required height, and for standard trees much time can be saved by budding at the necessary height up the stock. The dwarfing stocks for Cherries is the Mahaleb, and this should be budded close down to the ground-level. Cordon-trained trees succeed admirably on this stock, and pyramids make neat, compact and fruitful trees.

APRICOTS are generally budded on Plum-stocks, one known as the Brussels stock suiting most varieties. If standard trees are required, the Brussels-stock is used as the stem, the budding being executed at the required height. By budding the Brussels-stock on to the Mussel Plum the stem grows much faster, and is also cleaner in growth and freer from knots than if grown on its own roots. The Myrobalan Plum will also answer as a stock for the Apricot, but I do not regard the growth from this stock as being so free, and furthermore I am of the opinion from my experience that trees grafted on the Myrobalan are more liable to canker, and die through the hard nature of the stock being imparted to the Apricot.

APPLES.—Various stocks are used and various results are obtained in working the Apple. It is a matter of vital importance that the grower should have some knowledge as to the kind of stock his trees are growing upon. There are but two kinds of stocks on which the Apple can be said to do well, one being the Crab stock, which is suitable for all forms of trees where quick growth is needed, and the other is the paradise stock, of which two or three forms are now in commerce, including the English broad-leaved variety, which is the best. This stock should be budded low down, so that the union of the stock and the scion, often an ugly formation, may be hidden below the surface of the soil, where it often develops roots, to the additional benefit of the tree.

PEAR trees are budded on the common Pear, its most natural stock, and upon the Quince stock, for dwarfing and early fruiting purposes. There are a few kinds of Pears which will not grow successfully when budded directly on the Quince, but require budding on to another variety, which will succeed on the Quince. The Quince stock is more adapted for budding than for grafting, and in common with all the dwarfing stocks should be worked low down the stem. Weak-growing kinds required as standards are obtained by budding a strong-growing variety such as Pitmaston Duchess on to the Pear stock, and when the necessary height of stem has been attained, the required variety is budded at the desired place.

PLUMS.—For budding the Plum several kinds of stocks are used, but to be successful an intimate knowledge must be gained of the different varieties that are suited to the various stocks. Many stocks are obtained from suckers. The stock suiting most varieties is the common Mussel, which produces few suckers, and is propagated chiefly from root cuttings, as also is the Brussels-stock. The Myrobalan Plum is used with good results by some nurserymen as stock for Damsons, but it should be worked late in the season when the sap is not excessive.

PEACHES AND NECTARINES.—To be successful in budding the Peach and the Nectarine much attention and study are needed. Stocks as nearly allied in constitution to the variety to be worked must be used. Feeble growth, unfruitfulness, and premature death are some of the failures attributable to unsuitable stocks. Up to the present time no universal stock for these fruits has been discovered, but nurserymen of repute test for themselves the suitability of the stock which they use, zealously guarding the secret of their success. The character of the trees and of the fruits are somewhat changed by the use of various stocks. Up to the present time the broad and shining-leaved Mussel Plum is used, as is also the Brussels for some few kinds, while some varieties succeed only on the Brompton stock. In selecting buds of Peaches and Nectarines those with single leaves should be neglected, as should those with too prominent triple leaves. *W. H. Clarke, Aston Rowant Gardens, Oxon.*

ENDOWMENT OF HORTICULTURE.—Property to the total value of £338,026 14s. 7d., including net personalty £315,029 0s. 1d., has been left by Mr. JOHN INNES, J.P., of Manor House, Mostyn Road, Merton, Chairman of the City of London Real Property Co., Ltd., and Merton Park Estates Co., Ltd., who died on August 8, 1904, aged seventy-five. The testator left the Manor House and the residue of his property upon various trusts for a horticultural college or public museum and recreation grounds. This or a similar paragraph has been "going the rounds" for some time, but nothing definite is known about the statements therein made in quarters where knowledge might be anticipated.

CAMPANULAS OF THE CARPATICA GROUP.

THE genus *Campanula* is very rich in beautiful species, and there are a few good garden-raised forms also. It is somewhat surprising how little has been accomplished by the hybridist in producing important novelties in this group. Of late, however, more than one good variety has been seen

confined to the rockery, where they should be planted in free, rather open colonies or groups in their distinctive shades of colour. All the forms are readily increased by division of the root-tufts in spring, and this may be done in quite a free manner, a large tuft readily yielding a score of young plants. These small divisions are best potted for a time, to be subsequently planted in permanent positions. All the kinds grow quite

flower and style of branching. Usual height 18 inches.

C. c. pelviformis represents a distinct type; the flowers at first are nearly saucer-shaped, but eventually assume a flattened form. They are lilac or pale blue in colour, the stems freely branched; this is a very showy plant in those instances where it succeeds. In some gardens the plant does not do well, and generally the variety is less robust than the other members of the group.

C. c. Isabel.—This handsome form belongs to the pelviform section, as is evidenced by the flowers, of which so fine a lot was displayed recently at one of the Royal Horticultural Society's meetings. The flowers are 2 inches across, of deep violet-blue colour, and profusely borne on short peduncles. This is an ideal garden plant, and quite an acquisition. A bed of this kind constitutes a feature in any garden. Height 15 inches.

C. c. turbinata is a very dwarf plant not more than 4 inches high, with large purple-blue flowers produced above a cushion of greyish leaves. It is a most desirable rock plant. There are many inferior varieties sold for this plant, but the true kind is obtainable in the best nurseries.

C. c. Riverslea is another meritorious kind with deep blue flowers.

C. c. Hendersoni.—I believe nothing definite is known concerning the origin of this distinct form, but it has been assumed to have originated from *turbinata* crossed with *pyramidalis*, and the shortly pyramidal panicles of slightly drooping blossoms and spreading tufted habit are just what one might expect from the intercrossing of such widely different types. The plant is not a good grower generally, but in certain localities and soils it makes a fine bush and flowers freely.

C. c. White Star (see fig. 50).—I believe this excellent white variety and the variety *Isabel* were seedlings from *C. c. Riverslea*. If this is so it is interesting to note that *Isabel* partakes of the pelviform character in the flowers, a feature quite absent in the above-named kind, which is like *C. c. turbinata* in habit and compactness. Apart from this, it is not too much to say that "White Star" is the finest thing among the white Carpathian bell-flowers yet seen. The flowers are 2 inches across, white, with a blue ring encircling the ovary at the base of the corolla internally. This is a really fine plant, height as at present known 6 or 8 inches. "White Star" and *Isabel* were raised by Mr. M. Prichard, of Christchurch, and the twain are worthy additions to the group and are really first-class summer-flowering perennials. *E. H. Jenkins, Hampton Hill.*

FIG. 50.—*CAMPANULA CARPATICA* "WHITE STAR."

in excellent condition at the Royal Horticultural Hall, Vincent Square. The various kinds are all easy of cultivation, and worthy of being included in any choice selection of hardy perennials. Those most nearly allied to the species *carpatica* are by their taller growth and free flowering habit well adapted to border cultivation; nor will these same kinds be out of place in the well-kept, well-planted rockery. Those forms more closely resembling the turbinata section would by reason of their dwarfness be best

well in deep, well-drained soils, and the majority succeed either in light or heavy soils. Provision should be made in the original planting, and more especially for the larger-growing varieties, for a tuft of growth that in the third year may reach 2 feet across.

The forms that assume these proportions are *C. carpatica* (type) with deep blue, broadly campanulate, erect flowers on freely-branching, leafy stems. *C. c. alba*, *C. c. pallida*, of which there are at least two forms, are alike in habit, forms of

THE ROSARY.

FRAU KARL DRUSCHKI—A QUESTION OF PRECEDENCE.

THERE can be no question as to the beauty of this Rose, a cross between *Merveille de Lyon* and *Caroline Testout*, but a doubt has arisen as to its proper name. It appears that it was exhibited at various places in Germany by its raiser, M. Peter Lambert, as *Schnee Königin* (Snow Queen), but at that time it was not in commerce. When M. Lambert offered it in trade he sent it out under the name of *Frau Karl Druschki*. The question is, which name should have precedence? Was the exhibition of the Rose without description or figure to be taken as sufficient publicity? If it was, then of course the first name ought to remain—particularly if the Rose was certificated, as it probably was. But the public cares little for rules of priority; it has got to know and appreciate the Rose as *Frau* (or *Madame*) *Karl Druschki*, and not all the congresses will be able to effect a change. It will be remembered that a

similar question arose with reference to "Mrs. W. J. Grant." This lovely Rose was exhibited and certificated and, we believe, he-medalled under this name. The stock was sold to a firm of American nurserymen, who considered that as they had purchased the Rose they had the right to name it as they chose, and thus the name Belle Siebrecht is attached to it in America. We need not enter upon the ethical question whether the purchasers were right or wrong in their procedure. Assuming for argument sake that they were within their right, we are equally within ours by adhering to the rule of priority of publication, and in our trade catalogues, and particularly in official publications, precedence should be given to the English rather than to the American lady. *M.*

— FRAU KARL DRUSCHKI is probably the finest white-flowered Hybrid Perpetual Rose in cultivation. It is a good grower and free flowerer, producing freely long, pointed buds and broad petals. Every Rose grower should include this grand Rose in his or her collection. It is a fine buttonhole Rose.

KAISERIN AUGUSTA VICTORIA.

This Hybrid Tea is a Rose that is not met with in private gardens as often as it undoubtedly deserves to be. Its large clusters of creamy-white blooms are deliciously scented, and when seen in good condition never fail to excite admiration. If planted at the foot of a wall or fence having a west or east aspect in stiff soil enriched with short manure, it will reward the grower with a fine lot of blooms during the summer and early autumn months. If larger flowers are desired, the clusters should be thinned out to one central bloom.

MRS. W. J. GRANT.

This excellent Hybrid Tea Rose produces with perfect freedom bright rosy-pink and beautifully formed flowers which are pointed in the bud stage, and admirably adapted for buttonholes and for the adornment of small vases in the drawing-room, &c. The plant, too, is a good and free grower, and does well in bush form the second and subsequent years from the bud stage. In addition to the decorative value of the three Roses mentioned above, they also carry weight in the exhibition stands. *H. W. Ward, Tayleigh.*

KEW NOTES.

VARIOUS PLANTS IN FLOWER.—Amongst the very numerous plants now flowering in the houses the following are a selection of the more interesting and beautiful. As there are but few Orchids in flower at this time of the year, those that are in bloom are especially interesting. This is so in the case of *Stanhopea tigrina* var. *superba*, a very handsome variety, and of which Kew possesses a fine specimen plant, carrying twelve expanded flowers at the present time. This plant during the past month has developed thirty-six fine flowers. *Catasetum* now blooming are *C. tabulare*, *C. Darwinianum*, *C. fimbriatum* (with three good flower-spikes), and *C. macrocarpum*. *Cyanocheilus chlorochilon* and *C. pentadactylon* are also in flower. *Habenaria leonensis* is a delightful small-flowered species with white flowers. *Bulbophyllum grandiflorum* is very fine just now, with nine of its large and extraordinary-looking brown flowers. *Angraecum caudatum* and *A. articulatum* are also worthy of note. *Phalænopsis cornu-cervi* is a pretty and rather rare species. *Warszewiczella cochlearis*, *Sobralia Sandersoniana*, *S. Veitchii*, *Lælio-Cattleya bletchleyensis* are all choice and beautiful Orchids now flowering at Kew. *Lycaste leucantha* is a distinct species, with green sepals and white petals.

In the Victoria-house *Odontadenia speciosa*, trained on the roof, is in fine condition at the

present time. *Mascarenhasia Curnowiana* is an old species, with Vinca-like blossoms of a bright red colour; it is now flowering in the stove.

In the Nepenthes-house are several profusely-flowered baskets of *Æschynanthus grandiflorus* and *Æ. speciosus*, both with large and beautiful red-and-yellow-coloured flowers. *Costus igneus* is also flowering in the same house. *Hæmanthus Nelsoni*, *H. carneus*, and *H. Katherinæ* are very bright in the Cape-house.

Amongst the numerous interesting plants flowering in the succulent-house, *Stapelia gigantea* is perhaps the most curious, with its large, stellate, hairy, evil-smelling flowers; *Dychia leptostachya* is a beautiful species with red flowers, borne on an erect spike 1½ foot in height; *Bougainvillea spectabilis* var. *lateritia* is a very sparsely-flowered variety with brick-red-coloured bracts; *Kalanchoë kewensis*, *Bomarea edulis*, and *Testudinaria elephantipes*, the "Elephant's Foot," are also in bloom. In the same house *Solanum Wendlandi* flowers wonderfully well; it has been a mass of bloom for the past two months.

In the Palm-house the very curious *Mucuna imbricata* is flowering, having large pendent spikes of nearly black flowers that somewhat resemble a bunch of black Grapes. Other climbers with a good show of flowers are *Bignonia purpurea*, *Thunbergia grandiflora alba*, *Passiflora quadrangulosa* and *P. cœrulea racemosa*. *Ardisia Oliveri*, which is the most showy species of the genus, is flowering on the side stage, as are also *Goethea strictiflora*, whose bright red flowers are crowded on the erect stems; *Gustavia gracillima*, which develops on the woody growths its large rose-coloured flowers, with a pleasant spicy odour; and *Mussaenda macrantha*, which has orange-red, star-like flowers, each with a pure white bract measuring 3 inches in length by 2 inches in breadth.

In the Lily-house, *Nymphæa gigantea* is very handsome. *Arauca grandiflora* is very beautiful, with its long festoons of large *Stephanotis*-like flowers. *Bougainvillea spectabilis* is flowering profusely, although generally it is very shy in flowering. Outside this house is a recess containing about a dozen plants of *Romneya trichocalyx*, which are flowering very freely indeed.

In the numerous recesses around the Palm-house are grown various tender bulbous and other plants, which receive no other protection during the winter than that afforded by the house itself. *Opuntias* flourish remarkably well in some of these bays, and during the past two months have produced a fine display of flowers. At the present time *Crinum Powellii rubrum* is the finest plant in flower in these recesses. The plant is carrying a large mass of foliage, and fifty scapes of flowers, some of which are 4½ feet high. *C. Powellii* var. *alba* is another beautiful variety now in flower. Other plants that are now at their best in these positions are *Roscoea purpurea*, *Cypella plumbea*, *Agapanthus umbellatus*, *Gladiolus dracocephalus*, and *Tigridia Pavonia* and its varieties.

On the wall of the Economic-house a fine old plant of *Capparis spinosa* is wreathed in its beautiful white flowers. The plant is pruned hard back every spring, a treatment afforded *Punica Granatum* var. *nana*, now flowering on the wall outside the *Sarracenia*-porch. *W. H.*

MACLUDRANIA HYBRIDA.—In a recent number of the *Revue Horticole*, M. ANDRÉ describes and figures an interesting bigeneric hybrid raised by himself from *Maclura aurantiaca* fertilised with the pollen of *Cudrania triloba*. The female parent was a spineless variety of *Maclura* (the Osage Orange), but the hybrids, now eight years old, are spiny, and have the habit of *Cudrania*. They have not as yet flowered.

LEAVES FROM MY CHINESE NOTE-BOOK.

(Continued from p. 125.)

May 18.—At 9.40 we passed the village of Shih-Kai-Tu, on the right bank. Just opposite here, on the left bank, are three curious shrines—two large and one small—excavated out of the rock. Some distance above Shih-Kai-Tu the river, having forced itself through a gorge, expands into lake-like dimensions. The place is called Hsin-Tu. We entered the gorge, which is about two miles long; the country assumed a wild and rugged appearance, and there was little cultivation carried on. Coal occurs here, and lime is burnt.

Several large Orange groves are conspicuous. Hereabouts *Phyllostachys mitis*, with its beautiful green feathery culms, enters largely into the composition of the flora. Scrub Oak and the Cypress clothe the hillsides, and the tops are capped with Pine trees.

We passed a pagoda and fine temple amidst trees, and moored our boat at the town of Chang-Shou. Pagodas form one of the chief architectural features, no town of importance being without one or more. They always crown some lofty eminence, and by warding off evil influences ensure good luck for the town. They are nearly always white and of many stories, seven or nine usually.

The only fresh plants to-day were *Sambucus javanicus*, *Melastoma candidum*, *Aralia spinosa*, and a species of *Rubus*. The *Rubus* is allied to *R. phœnicolasius*, from which it differs in having truncated apices to its trifoliate leaves, and yellow fruits. The fruits were ripe and of excellent flavour. *Lysimachia ophelioides* was very abundant to-day. *Boehmeria nivea* is cultivated in small patches. I noted some women removing the bark by hand. *Fatsia papyrifera* is also cultivated, but only in small quantities. Maize and Tobacco were the principal crops, the Opium which preceded these crops being all cleared away. Rice is grown in all places where irrigation is possible.

During the last two or three days the increase in the quantity of Tobacco grown was a very striking feature. This crop occupies the ground for eight or nine months. The seed is sown broadcast in small beds in November or December, and transplanted in drills about 6 inches apart in February or early March. As the plants grow they are earthed up in the same manner as is Opium. After they have made about ten large leaves, the tops are pinched out and all lateral growths carefully removed. The lowest leaves are removed and dried. The first cutting is made at the end of April or in May, the whole plant being cut down level with the ground. The plants spring up again, and a second cutting is made about a month afterwards. Occasionally a third cutting is made. Tobacco is rather a "hungry" crop to grow, but a well-paying one withal. The Tobacco plants are perfectly at home in the red basin of Szechuan, and the crops are extraordinarily luxuriant. The Chinese tend them with the greatest care, and could they cure the leaves as well as they cultivate the plant, their product would find a ready sale in Europe and elsewhere. On the mountains *Nicotiana rustica* takes the place of *N. tabacum*. The Chinese distinguish many varieties, and certain districts are noted for the quality of their tobacco.

May 19.—The walls around Chang-Shou enclose a very considerable area, only a portion of which is covered with houses. Indeed the town is disappointingly small. The river rose 10 feet in two days. The water is of a brick-red colour and soupy, the current very strong.

We reached the small but busy village of Lo-tsi at 4 P.M. This is another noted mart for mats and tracking-lines, and also for timber. The

timber is mostly "Peh-mu" (*Cupressus funebris*) and "Sha-mu" (*Cunninghamia sinensis*), used in boat-building, and is brought down from Mu-tung. Lo-tsi seems a cheap place for Cabbage—large Shan-tung Cabbages with firm hearts were 6 cash (about $\frac{3}{4}$ d.) each, the large white-ribbed Chinese Cabbage 5 cash each. We purchased a large stock—so large, in fact, that I am at a loss to know what they will do with them all.

Above Lo-tsi a shingle bank extends for over a mile. Near the end of this we saw a couple of human heads exposed in cages at the top of a pole. They originally belonged to a couple of men convicted of highway robbery with violence.

We moored for the night 6 miles below Mu-tung, where the river is strewn with huge rocks, and has a very dangerous appearance. The only fresh plants were *Commelina communis*, *Hypericum ascyron*, *Nepeta Everardi*, *Ilex Oldhami*, and *Viscum articulatum*.

The Mistleto (*Loranthus*) was growing on *Aleurites cordata*; hitherto I have only met with it on *Pterocarya stenoptera*. This may be a different species.

Oldham's Holly is not the least handsome of the genus. The flowers are rosy-purple, and very fragrant; the leaves smooth, shining, and soft in texture. It makes a tree 15 to 20 feet high, and is fairly common from Ichang westward in the immediate vicinity of the Yang-tszu.

May 20.—After our usual 5 o'clock start we reached Mu-tung at 8.30 A.M. Soon afterwards we crossed a lake-like expansion of the river, and entered a short gorge where coal is mined and lime burnt. Passing through more open and well nigh treeless country, we entered the Iron Gorge; this is only about a mile long, but wild and rocky, with no tracking-path. The sides of this gorge are covered with a dense growth of Scrub Oak.

Emerging from this gorge and crossing with difficulty another of those curious lake-like expansions, we reached the lower barrier of the Imperial Maritime Customs. I stayed the night here, and enjoyed for a few hours the companionship of a European. This man kept silkworms, several animal pets, and collected old cash, but he had little information to impart.

Sugar-cane, both red and white, was common to-day. I had noted it in several places the last two or three days. The red variety is cut in the early winter and buried beneath soil in the way we do Potato or root-crops, save that the canes are arranged more or less vertically. The white variety is evidently more hardy and is allowed to stand, being only cut as required.

Sorghum vulgare was cultivated. The Tobacco crop looked very promising, and in places the first cutting had been made. As a weed of cultivation *Carduus crispus* was common. I collected nothing fresh to-day, but noted two trees I have omitted to mention hitherto, viz., *Phellodendron amurense* and *Hovenia dulcis*.

May 21.—We left at 6 A.M., and reached the French Naval Station at 10.30 A.M. This is situated a couple of miles below the city of Chung-king, and on the opposite bank of the river. Having stayed to lunch with an old friend here I rejoined my boat at the Customs pontoon. The necessary business having been concluded and a permit granted, we crossed the river and moored just above the Tai-Ping-Mêng. Very glad was I that the first part of my long trip was accomplished with so few mishaps. My boat safely moored I hired a chair and visited my old friend, W. C. Haines-Watson, Esq., the present Acting-Commissioner of Customs here. It took half an hour to reach his quarters, the journey being through the city. We skirted the wall, through narrow, filthy side streets. The people were evidently quite used to foreigners and took no notice whatever of me. My friend greeted me warmly and invited me to stay with him during the time I remained in Chung-king. The

meeting of old friends in such out-of-the-way parts of the world can easily be imagined. I will only add that in an hour or so the fatigue, monotony, and dangers of the voyage were forgotten, and we were chatting about mutual friends and familiar scenes in the dear old homeland. E. H. Wilson.

BLUE CONIFERS.

THERE are several Conifers that have foliage of a glaucous hue, varying in intensity from the greyish-green of some of the *Cupressus* to the nearly Cambridge-blue of a well-coloured Blue Cedar. The amount of glaucousness varies considerably with the different species and varieties, and has no relation to their hardiness, though, as a rule, the higher and better the colour the slower is the growth of the plant. A glaucous variety of any Conifer is always slower of growth than the type when grown under the same conditions, though the hardiness or otherwise of both is equal. There is, however, no question as to the beauty of some of these glaucous Coniferae, more especially as this particular tint of foliage is not found to any great extent except in this Order. In other classes of trees and shrubs glaucousness is only found on the undersides of the leaves, rarely on the upper surface; but in the glaucous Conifers it is a characteristic of the whole plant. The following can be recommended as a good selection, and include practically all the better-coloured plants of the Order.

CUPRESSUS.

C. Lawsoniana var. argentea.—This somewhat resembles the type in habit, though the branches are longer and more slender. The foliage is of a bright silvery glaucous hue, which is of very effective appearance. It is also met with under the varietal name of *glaucous*, though sometimes this has a Latinised form of someone's name attached to it in addition.

C. L. var. Alumi.—This is an erect, fast-growing plant, with flattened, upright branches, and in a young state is not a very handsome plant. With age the growth thickens considerably and takes on a bright, glaucous tint, which is at its best in winter.

C. L. var. Smithii is a pillar-like plant, retaining the same diameter throughout to whatever height it grows. The branches are short and spreading, and gracefully pendent at the extremities. The foliage is of a bright greyish-green hue, and the plant can be recommended as one of the most distinct and desirable of the varieties of *C. Lawsoniana*.

These three plants should for preference be grown on moderately dry, light soil, where the growth, if slower, is more highly coloured than when they are situated on richer and damper ground. They are easily propagated from cuttings.

C. pisifera var. squarrosa (*Retinospora squarrosa* of gardens) is a dense-growing plant, with numerous spreading branches clothed with acicular leaves arranged in opposite and alternate pairs. The whole plant is of a light glaucous-green, approaching a silvery-whiteness in spring, and when well grown is one of the handsomest of the Conifers with Fern-like foliage. It requires a deep, cool, moist soil and an open situation, as it gets very thin and ragged on dry ground, and does not grow well in smoky districts. It is also propagated from cuttings.

JUNIPERUS.

J. excelsa var. stricta (*glaucous*).—This plant attains to a height of from 12 to 15 feet with age, and is of a pyramidal shape, with every branch symmetrically arranged in its proper place. The foliage is very fine in texture, and is covered with a greyish-blue tint, which, combined with

the handsome appearance of the plant, render it a suitable subject for the garden.

J. virginiana var. glauca (the Silver Juniper).—This is a fast-growing plant, though not quite so free as the type. When well grown it forms a handsome, upright specimen from 12 to 20 feet in height, with slender branches clothed with fine foliage of a silvery-blue colour, which is effective at all seasons. It requires watching in a young state to keep it to a single leader, and if the points of the side-shoots are cut out at the same time, the plant makes a denser growth, and is also less liable to be broken by snow. These Junipers will grow in almost any soil, but should have a position fully exposed to the sun, as they turn to an unhealthy greenish tint in the shade. They are propagated by grafting on stocks of *J. virginiana*.

ABIES.

Abies concolor var. violacea.—The varietal name of this plant is considered by some to apply to the colour of the cones, but in gardens it is used in connection with a glaucous form of *A. concolor*. The leaves are 2 inches or more in length, narrow, and apparently arranged in double rows. The colour is somewhat variable, but is usually of a pale glaucous-blue, increasing in intensity with age. A large plant of good colour forms one of the handsomest specimen Conifers.

A. nobilis var. glauca.—This name is applied to the more glaucous forms of the type, and when well coloured they are very handsome and ornamental. The leaves are crowded on the upper part of the stem and apparently two-ranked beneath, varying from $\frac{1}{2}$ to 1 inch in length. They are covered with a glaucous bloom. As these two species of *Abies* make large trees upwards of 80 feet in height, they should be planted in a deep soil, and also have plenty of room to develop. They are increased by seeds.

CEDRUS.

Cedrus atlantica var. glauca (the Blue Cedar) is a well-known and deservedly popular tree, and at the present time there are many fair-sized specimens in various parts of the country. In a young state it is a thin upright plant, with but few side-branches, but with age it develops into a handsome pyramidal tree of a bright glaucous-blue colour.

C. Deodara var. verticillata, glauca.—This is a form of the Deodar, with long, straight, regularly whorled branches, pendulous at the ends, and clothed with glaucous-blue foliage. It is slower of growth than the type, but will probably make a handsome tree when fully developed. It is comparatively new at present. Highly glaucous forms are sometimes found in batches of seedling *C. Deodara*, but these rarely grow to any size, and more often than not they die within a few years. Both these Cedars are propagated by grafting on stocks of the type species. The former comes true to a certain extent from seed, but up to the present the young plants have not been very satisfactory.

PICEA.

Picea ajanensis.—This is a species from Japan, and belonging to the flat-leaved section of the Spruce Firs, differs from the other Spruces in having flattened instead of four-angled leaves. The leaves of *P. ajanensis* are about an inch long, blunt at the tips, dark shining green beneath, and brightly glaucous above, contrary to what is usually the case. Strictly speaking it is not a glaucous Conifer, but the side shoots have a tendency to curve upwards, and display the light blue uppersides of the leaves, which is seen to advantage under a low winter sun. It is a slow but uniform grower, and delights in a deep, moist soil and a sunny situation. It is propagated by seeds. [The position of the leaves in this species, which has often given rise to

misapprehension, is fully described in the Linnean Society's *Journal*, vol. xviii., in a memoir on the Conifers of Japan. Ed.]

P. pungens var. *glauca* (*Abies Parryana glauca*).—This is a plant that is largely grown in English and continental nurseries, but in this country at least it is a considerably over-rated plant. The leaves are about $\frac{3}{4}$ of an inch long, rigid and sharp-pointed, and arranged all round the light brown stems. They are covered with a light blue, glaucous bloom, which on a well-coloured specimen is very fine, and shows to advantage on a lawn or against darker-coloured plants. It makes a good specimen up to about 8 feet or so in height, but after that it begins to lose its lower branches, and gradually dies out. It requires a deep, moist soil and plenty of room, when it makes a grand specimen for the time it keeps good. The practice of grafting this plant is a great mistake, as grafted plants never grow upright unless tied up to a stick, and even then they are usually unshapely. It can be raised fairly true from seed, and the poor-coloured seedlings weeded out.

THE DOUGLAS FIR.

Pseudotsuga Douglasi var. *glauca*.—This is a glaucous form of the Douglas Fir, but is a very slow-growing plant compared with the type. It makes a good ornamental tree, but is of no use to plant for timber, its rate of growth being too slow, and from its appearance it will never attain to any size sufficient for timber. It will grow almost anywhere, and is raised from seed.

TSUGA.

Tsuga Pattoniana var. *glauca* (*Abies Hookeriana*).—This is a slow-growing large bush or small tree of about 12 feet or a little more in height. In habit it forms a broadly-pyramidal specimen with many leaders if left unchecked, but if kept in shape it forms one of the handsomest of small specimen Conifers. The branches are irregular and comparatively stout; and the secondary branches appear as short spur-like growths at first, gradually lengthening with age, and producing other short growths at irregular intervals along their stems. The leaves are rather less than an inch in length, curving upwards, somewhat triangular in section, and brightly glaucous all over. They are arranged all round the stems, which are dark brown in colour, and covered with a woolly felt. The plant requires a deep, moist soil, and thrives best if some good leaf-mould or peat is given in addition. It is propagated by seeds, which produce plants variable to a certain extent in colour, but which are usually well-coloured. I have never seen it grafted, but it would probably do well if worked on *T. canadensis* or *T. Mertensiana*.

There are a few other glaucous Conifers that I have omitted, but they are either poor of growth or are tender in this country, and cannot therefore be recommended. The following Pines have foliage of a glaucous tint—viz., *Pinus sylvestris* (The Scotch Pine), *P. Cembra*, *P. excelsa*, *P. parviflora*, and *P. Strobus* (the Weymouth Pine). *J. C., Bagshot.*

The Week's Work.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Phlox suffruticosa and *decussata*.—Cuttings of these plants should now be propagated in cold frames, inserting them in a sandy compost with a layer of sand on the surface. Choose sturdy cuttings that are not flower-growth. Shade them from bright sunshine until they are rooted, when they should be allowed free ventilation on all favourable occasions. Amongst the late-flowering section the variety *Coquelicot* forms a good "front row" plant, the colour of its beautiful flowers being bright orange-scarlet. Another desirable variety is *The Mahdi*, the colour of its flowers being a good violet-blue. The dwarf varieties are very distinct, and of a neat habit with large heads of bloom. The following are a few good varieties with their colours of this section:—*Argon* (rich rose), *Iris* (bluish-violet), *The Queen* (white), *Mars* (rosy-salmon), *Aurora* (coral pink), *E. Lockray* (salmon).

Pentstemons.—The present is a good time to propagate these plants, selecting for the purpose side-growth without flower-spikes. Treat them in the same way as *Phloxes*. *P. Newbury Gem* is a dwarf-growing variety bearing a profusion of scarlet-crimson flowers all through the summer; *P. cœruleus*, *P. barbatus* *Torreyi*, *P. heterophyllus*, *P. humilis*, are useful species, the last-named being a dwarf-growing, rock-garden plant easy of culture.

Carnations.—Proceed with the layering of these plants in earnest. The border intended for the reception of these plants in the autumn should be prepared now, so that it will be in good condition when planting time arrives. Choose an open quarter, as Carnations resent shade and over-shadowing. If the site is protected from north and east winds it will be advantageous. The border should receive a good dressing of old hot-bed manure, a little mortar rubbish, a sprinkling of bone-meal, and as much virgin loam as possible. Trench the ground two "spits" deep, at the same time well mixing the component parts.

Roses.—Keep the growth free from mildew and other fungoid pests by an application of sulphur. Hoe and water the plants when required. Remove all old flowers and dead wood. Late-summer and early-autumn flowering *Roses* are a desirable class for planting in heds. The variety *Gruss an Teplitz* is our best variety, some trusses developing over fifty flower-buds. *Marquise de Salisbury* is another very free-flowering variety. Other desirable varieties are *Madame Lambard*, *Marie van Houtte*, *Souvenir de Président Carnot*, *Madame Pernet Ducher*, *Viscountess Folkestone*, *Corallina*, and *Exquisite*.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Odontoglossum Rossii is an Orchid of such merit that it is surprising it is not more generally grown. It is amongst the first to be recommended for an amateur's greenhouse, as it will stand rather harsh treatment without much apparent injury. It needs very little artificial heat, and furnishes a good supply of long-enduring flowers, provided the plant's requirements as to growth and rest be closely observed. After having rested for several months, the new growths are now developing, and when these have attained to a length of about an inch, the necessary potting operations should be performed. *O. Rossii* grows and flowers well in pans provided with an inch or so of drainage, and a compost composed of a couple of inches of a mixture consisting of equal parts of peat and moss, a fifth part of decayed Oak-leaves, with a dash of sand added, and a surfacing to the whole of about half-an-inch of chopped moss. The base of the plants should be on a level with the rim of the pans, and the materials made moderately firm, with the moss placed well up to the growths, but not in the form of a mound. The pans should be suspended near the roof-glass of the *Odontoglossum*-house, where plenty of light and air is to be had. Plants that do not require repotting should have the old surface-moss removed and replaced by fresh, afterwards giving sufficient water to keep the whole body of material moist. Plants that have been repotted should be less liberally treated with water, a sprinkling once or twice a week until their roots have ramified in the new materials should suffice. As growth advances and the pseudo-bulbs commence to swell dryness at the roots must not be permitted, but, on the other hand, excessive saturation must be avoided. Weak floral scapes which may appear in the young growths should be removed.

Odontoglossum Cervantesii needs similar position, conditions, and treatment to the above, with the exception that small perforated pans, with drainage and a little peat and moss, are preferable, the latter suiting them better than the leaf-soil mixture. Much water only is needed when growth and root-action are most vigorous, the atmospheric moisture being almost sufficient at other times. New receptacles or fresh materials may be given soon after growth has commenced.

Odontoglossum Oerstedii grows best when planted in well-drained pans with a mixture of peat and moss, mounded well above the rim, so that prolonged saturation is almost impossible. Being of a tufted habit and of a sparsely-rooting nature, disturbance at the roots should only occur when absolutely necessary, an annual renewal of the surface materials being generally sufficient for their needs. Suspend the plants in a similar position to that advised for the above-mentioned species. Give water very sparingly, even when growing freely. When not in this condition absolute dryness is essential to success.

Odontoglossum aspersum and *Humeanum*, natural hybrids of this section, grow well either in pots or in pans, planted in leaf-mixture. They should not be far removed from the roof-glass, and must be kept well moistened when growing freely.

Odontoglossum nebulosum should be repotted or resurfaced when new roots are about to develop from the young growths. The plants grow well in leaf-mould mixture in pots that are provided with drainage to half their depth. The leaf mixture should be covered with chopped moss to the depth of half an inch. Stage the plants near to the glass in the highest part of the cool-house, and give water very sparingly at all times.

Odontoglossum Harryanum.—This distinct *Odontoglossum* usually blooms during August, and the flowers, which will remain in condition for a long period, must be removed soon after they have expanded, in order to prevent undue exhaustion of the plant. When the flowers are removed allow the plants a good rest by withholding water, and continue this treatment until shrivelling is imminent. The plants should occupy a central position in the house, where moisture and shade can be plentifully afforded, and thus obviate all injury from undue dryness.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Onions intended to be stored for winter and spring use must be firm and well ripened before storing. If they are taken up and exposed to the sun's heat for a few days by being well spread out with the roots toward the sun, and afterwards stored in a dry place from which damp and frost are excluded, there is little fear but that they will keep well, especially after the spell of bright sunshine we have recently been experiencing. If the plants have been raised from seed sown in boxes and afterwards transplanted, the bulbs will still be swelling freely (a clear illustration of the advantage gained by this practice). These should be examined, and any of the tops that are still erect should be bent down in order to assist the bulbs to swell and ripen. When storing the bulbs it is well to do so in three sizes, for it not infrequently happens that they are required in various sizes for culinary purposes.

Cabbages.—The practice of rotating the Onion crop with early Cabbages has something to recommend it, for the ground having been previously well prepared by deep cultivation and by liberal manuring at a season when the influence of the weather pulverises and sweetens the soil, it will be in excellent condition for the crop of Onions. But these two crops should not occupy the same ground for a longer period than two consecutive years if it can possibly be avoided. As a preventive against the enemies of the Cabbage family apply a dressing of lime to the soil a few days before planting, and at the time of planting some soot. Plant in drills 3 inches in depth and 18 inches apart, and 12 inches between the plants in the rows. As a variety for early work *Ellam's Early* is unsurpassable.

Potatos.—Second early varieties will now be quite ready for lifting, and this work should be done at once, for in the event of wet weather disease will rapidly attack them. The practice also of allowing *Potatos* intended for seed purposes to lie exposed to the weather when disease is at all noticeable should be guarded against, for newly-lifted tubers soon become affected with the disease.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Souvenir de la Malmaison Carnation.—Plants that were layered as advised early in July will now be well rooted, and should be lifted from the beds and potted before they commence growing; but before potting allow the young plants to remain for about a week detached from the old stocks. This is an important matter, and considerably reduces the check the plants would otherwise receive. In the meantime, prepare a suitable compost composed of two parts loam, one of leaf-soil, and one part of silver-sand, and well mix the whole together. The pots to be used, if new, should be well soaked in water and allowed to drain before being employed. Those that have previously been in use must be thoroughly cleansed and dried before being used again. Give plenty of drainage in the shape of broken crocks, and after potting stand the plants in a cool frame and keep the atmosphere close, and the glass shaded for a few days. The young plants readily adapt themselves to this treatment. As soon as they show signs of activity shading must be dispensed with and air freely admitted.

Caladiums.—As these plants show signs of resting let them be placed where they can receive the full benefit of air and light, at the same time gradually withhold water from the roots, but continue to apply diluted manure-water until the foliage begins to turn yellow.

Palms.—The present is a good time for potting or top-dressing these plants. A suitable compost consists of three parts good rich loam to one of leaf-soil, to which should be added a little broken charcoal and silver sand, while to each barrowload of compost a 4-inch potful of Clay's Fertiliser should be added. Keep the plants well syringed and shaded after potting, and apply water at the roots judiciously.

Chrysanthemums.—Daily attention must be given to the tying, &c., of the plants, as strong winds or birds alighting on them easily break the shoots.

Streptosolen Jamesoni.—Cuttings of this useful plant are now easily procured, and if they are now propagated will furnish good plants for another season. Providing a little bottom heat is given the cuttings root readily.

Fuchsias.—Plants intended to furnish a supply of autumn cuttings should be well ripened by this time, and must be placed in a warm, close house, and freely syringed overhead. Propagate the cuttings as soon as they can be obtained.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM FLOWDEN, Aston Rowant House, Oxon.

Apricots.—Now that these fruits are ripening they should receive the full effects of the sun's rays, and any leaves which intercept light and air from the fruit should be removed, as fruits ripened on the trees are much superior in flavour to those artificially ripened. Great care and attention are required to protect the fruits from the ravages of earwigs, woodlice, snails, &c. However diligent the cultivator may be some of the fruits are sure to be spoilt by these pests, which seem to have a special liking for Apricots. Earwigs can be captured in the hollow stems of dry Bean-stalks cut in lengths of about 6 inches, also in Bamboo-canes placed between the branches. The traps should be examined each morning, and the earwigs destroyed by emptying them into hot water. Wasps will further the damage commenced by the above-mentioned insects, but these can be warded off by covering the trees with hexagon wasp-proof netting. I am of the opinion that bottles of sweetened beer, treacle, &c., used as traps for these insects attract them to the trees. The best plan of dealing with these pests is to destroy them in their nests.

Figs.—Trees that have become crowded with excessive growth should have their branches well exposed to sunlight and air, for unless the wood is well matured fruit-buds will not form. Trees on which the Figs are swelling should be assisted by applications of manurial stimulants, and every

encouragement given them to perfect their fruits. As soon as the trees have been cleared of all fruits likely to ripen, they should have all exhausted and useless branches removed, leaving only a sufficient number of this season's shoots that are strong enough to produce fruit next year. Only in very favoured situations will Fig-trees produce two crops of fruit in a season, therefore any forming at the present time should be rubbed off. Nail all shoots close in to the walls, as the heat radiating from the bricks will serve to harden and ripen them. Shoots growing beyond their limited space should either be pinched back to the fifth or sixth leaf or be trained down to the next growing shoot beneath.

Morello Cherries are now ripening fast, and should not be allowed to hang until over-ripe, otherwise the quality and flavour will deteriorate; but as the fruits do not, as a rule, all ripen at the same time, the trees should be looked over frequently. All shoots should by now be tied to the trellis. Some growers do not tie them until after the fruit is gathered, but they cannot then be secured so perfectly or so quickly as when the tying is performed earlier.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORRET, Impney Hall Gardens, Droitwich.

Midseason Vines.—As soon as the Grapes are all removed from these Vines, thoroughly syringe the plants with clear water in order to destroy red spider, and to cleanse them from dust, &c. Give liberal treatment to all plants that are weakened from continuous heavy cropping, and encourage as much lateral growth as possible, with the exception that strong laterals should be removed from too vigorous-growing Vines. Ripe black Grapes that are desired to hang in a good condition for as long a period as possible should receive plenty of shade during hot sunshine, for which purpose nothing is better than a covering of their own foliage with a little extra extension of lateral growth arranged about the bunches; but should the foliage be too sparse for this purpose, netting should be placed over them, or light shading may be used, which should be removed in the evening. White Grapes require plenty of sunlight until they are thoroughly ripened, but even the more exposed bunches of these should have a sheet of tissue paper placed over them. Pay careful attention to watering, and keep the house cool and not in too dry a condition, maintaining a little heat in the pipes during dull or wet weather.

Late Vineries.—Endeavour to forward the Grapes in these houses as much as possible during the next few weeks now that all danger from scalding has passed. Ventilate the houses freely during the early part of the day, but not excessively, closing them early in the afternoon with plenty of sunheat and atmospheric moisture present, and at about 7 P.M. admit a little top and front ventilation to remain for the night. Houses situated in moist situations and on cold soils should receive a little artificial heat at night-time. Look to the bunches for the last time, and remove any crowded or seedless berries which have been overlooked. Pinch out all lateral growths and give generous feeding with liquid manure and other fertilisers until colouring is well advanced.

Melons.—These plants will now require more careful treatment with regard to watering and atmospheric moisture generally. Syringe the plants on bright days only, damping the paths, walls, and other available spaces only in dull and in wet weather. Keep the foliage in as healthy a condition as is possible, and avoid overcropping the plants with growth. See that the atmospheric moisture is reduced in those houses in which the fruits are ripening, where a free circulation of warm dry air must be permitted. Renew the linings of hot-beds in frames containing Melons in order to keep up the required temperature. Very little water will be necessary if the roots have penetrated into the moist fermenting material. All fruits must be fully exposed to sunlight; they should, moreover, be turned round occasionally to secure uniform growth.

THE APIARY.

By CHLOUIS.

Preparing Honey for Sale.—A well-prepared article of any description will always sell more readily than one which has had no care bestowed on it, although the latter may be of higher quality than the former. The eye of the consumer must be considered as well as his palate. Make honey look as attractive as possible, let every receptacle be scrupulously clean, and if the honey be of good quality it will command the highest market value.

Marketing Sections.—Sections should be graded into two, and often better into three divisions. Those of the highest grade should be: 1, the very best; 2, quite clear; 3, uniform in the sealing, including the cells next the wood; 4, light in colour. In examining the sections of a very good bee-keeper last year I saw three crates taken off one evening containing only four sections which did not fulfil every one of the foregoing conditions. They were sealed from the top to the bottom and from side to side, and were in no way travel-stained. Those of the second grade would fall a little behind the first in each of the four points named; and the third grade would fall a little lower again than the second. By dividing the sections in this manner the whole would command a much higher price than if they were offered for sale in a mixed state, and at the same time give greater satisfaction to the purchaser.

Crates for Sections.—Some years ago I had a conversation with a druggist who disposed of a large number of sections. The whole of them

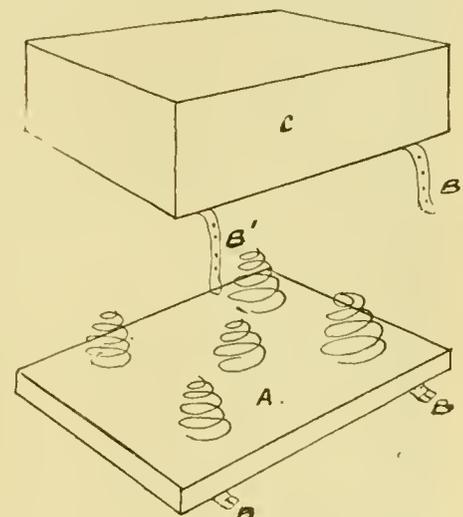

FIG. 51.—CRATE FOR DISPATCHING SECTIONS OF HONEY BY RAIL.

were sent by train a distance of 250 miles. During the whole period not a single section was damaged in transit. Naturally I was eager to learn how such excellent results had been secured. I found that they had been sent in crates of all descriptions, to which were fitted sofa springs cut in halves. The outside boxes were often old orange-crates. In the bottom of the outside box was fixed a board A, to which were fastened springs. On the long sides were fixed straps with buckles B. The sections were put in a lightly-made box, C, so that when the box was filled none of them could move. To this box were also fixed straps, B, so that it could be strapped tightly against the straps on the lower board, A. The lid, too, of the outer crate had springs fixed on it similar to those on A, but on the under side.

Extracted Honey.—It is a great mistake to mix honey which has been gathered from various sources. By adopting this method the fine aroma of each kind is lost. If the sale be local place the honey in clear glass jars, and on each fix a label giving the name of the apiary if desired as an advertisement, and also stating that honey granulates at a low temperature, but that it will resume its liquid state by placing the jar in a basin of hot water. When sending honey by rail it may be sent in tins specially prepared by the appliance manufacturers or in sweet tins hermetically soldered.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, AUG. 22—Brighton Horticultural Society's Show (2 days).
 WEDNESDAY, AUG. 23—Shropshire Horticultural Society's Exhibition at Shrewsbury (3 days).
 Arundel, Littlehampton, and District Horticultural and Agricultural Show.
 THURSDAY, AUG. 24—Aberdeen Flower Show (3 days).

SALES FOR THE WEEK.

MONDAY NEXT—Great Trade Sale, Dutch Bulbs, 4,000 lots.
 WEDNESDAY NEXT—Great Trade Sale, Dutch Bulbs, 3,000 lots.
 THURSDAY NEXT—Great Trade Sale, Dutch Bulbs, 3,500 lots, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 10 o'clock.
 FRIDAY NEXT—Choice Cypripediums, Cattleya, and Lelio-Cattleya Hybrids, Established and Imported Orchids, at 12.30; Liliun Harrisii and L. longiflorum and multiflorum received direct, Roman Hyacinths, Narcissus, &c., at 3 P.M., by Protheroe & Morris, at 67 & 68, Cheapside, E.C.
 (For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—61.3°.

ACTUAL TEMPERATURES.—

PROVINCES.—Wednesday, Aug. 16 (6 P.M.): Max. 68° W. Coast of England; Min. 57° N.E. Scotland.

Grafting the Carnation upon Saponaria.

The experiments made by M. GEORGES POIRAULT, of Antibes, have attracted so much attention among his fellow-countrymen that he has been asked to furnish further details of his methods. The object of the experiments was to ascertain whether by grafting Carnations on to the root-stock of Saponaria it would not be possible to render the Carnations immune to the fungous diseases which are so destructive.

In a recent number of *Le Jardin*, M. POIRAULT explains that it is better to use for this purpose plants two years old grown in pots. At the grafting season, which in the South is from December to February, the operation is effected. The graft is not made upon the stem, which at that season has died down, but upon the root-stock. Herbaceous grafting can be effected; in any case, it is better to use slightly hardened grafts. Cleft-grafting is available, but it is far better to employ the English method. The Saponaria is grown in pots, and the root-stock is turned out of the pot on to the potting-bench, grafted, and then replaced.

If Saponarias in pots are not available, it will prove quite as satisfactory to operate on plants in the open ground, which should be treated just as described. After grafting, the plants, covered with a bell-glass, are

put into a warm pit, where they remain for three or four weeks. Air is then given by raising the glass for a week, after which the cover can be removed. In the open ground the operation takes place in May. The plants are treated as Carnation-pipings.

In the experiments made at the Villa Thuret, so long under the management of our valued friend CHARLES NAUDIN, M. POIRAULT has not merely worked to produce flowers. His desire was to cultivate the Carnation on a disease-resisting stock, and further to see if the use of Saponaria would impart lasting immunity to the graft implanted on it.

In the South the Saponaria has the disadvantage of being late in coming into leaf, but this drawback is counterbalanced by the ease with which it can be forced.

The grafted Carnations flowered in December, and were over by January or February, a period corresponding with the resting season of the stock; they again bloomed at the end of February or March, when the Saponaria was divided. The Carnation-flowers were at every season as large and fine as those growing on their own roots. As to the immunity from disease M. POIRAULT has at present nothing to tell us.

QUEENSLAND.—Our Supplementary Illustration shows a view in the State Nursery, at Cairns, Queensland. The stately native Palms to the right are saddled with the terrible name Archontophoenix Alexandrae. Truth to say they look none the worse for it. The other Palm with drooping foliage is Cocos plumosa. To the left is a tree of Ficus elastica, and on the right one of Spathodea campanulata. In the foreground is Agave vivipara.

The *Brisbane Courier*, lately received, contains an article, with illustrations, which show what sort of work a Colonial botanist has to do, and what meagre remuneration is allotted for the possession of that most valuable asset—brains. From the article before us we gather that the labours of Mr. F. MANSON BAILEY are more highly appreciated in the Old Country than they are in the Colony, and this in spite of the fact that Mr. BAILEY has known how to turn his knowledge to practical account. Here we naturally value his scientific attainments and productions as being of cosmopolitan importance. But on the spot his fellow-colonists not unnaturally take greater interest in questions of practical moment, such as the identification and utilisation of grasses and other forage plants, the recognition of the various trees, and the development of the magnificent resources of the colony in the matter of timber, gums, resins, dyes, and other products. Mr. BAILEY had practical experience as a farmer and fruit-grower, both in New Zealand and South Australia before going to Queensland, and is therefore familiar with the requirements of the cultivator.

"The flora of Australia," says our contemporary, "has been the loving study of a keen and intelligent mind through many decades—a mind which has watched the life of Australian plants, especially those of Queensland, in good and bad seasons, on mountain, in valley, scrub, and forest, the plains of the interior, and the broken country of the coast, the personal study of a practical mind, coupled with an intimate knowledge of the writings of forerunners and contemporaries, and with keen insight into economic values."

In England we find Mr. BAILEY'S *Queensland Flora* most serviceable for the identification of plants from that tropical colony, the more so as, unlike other colonial Floras, it is illustrated.

THE TRIALS UNCERTAIN BY THE NATIONAL POTATO SOCIETY.—Potato trials of considerable interest are being conducted in various parts of the country, and may be inspected by members and others interested. The following are the counties, and intending visitors are advised in each case to communicate beforehand with the gentlemen supervising the trials, whose names and addresses are appended:

Berkshire.—Professor PERCIVAL and Mr. C. FOSTER, University College, Reading.

Surrey.—Mr. A. DEAN, 62, Richmond Road, Kingston-on-Thames

Warwickshire.—Mr. H. DUNKIN, Coventry Road, Warwick.

Somersetshire.—Mr. J. ETTLE, Stanley Grove Road, Weston-super-Mare.

Oxfordshire.—Mr. S. HEATON, Hill View Road, Oxford.

Northumberland.—Professor GILCHRIST, College of Science, Newcastle-on-Tyne.

Shropshire.—Mr. G. T. MALTHOUSE, Harper Adams College, Newport, Salop.

Cheshire.—Mr. W. NEILD, The College, Holmes Chapel.

Yorkshire.—Mr. T. REDINGTON, Agricultural College, Leeds.

Staffordshire.—Mr. J. C. RUSHTON, County Education Offices, Stafford.

Worcestershire.—Mr. J. UDALE, Ombersley Road, Droitwich.

Valuable trials are also being conducted at Burgoyne's Farm, Impington, near Cambridge (Histon station), by the Agricultural Department of Cambridge University, and may be inspected by members. The farm superintendent is Mr. H. HENSHAW. Messrs. POAD & SONS, York, and WM. DEAL, Kelvedon, Essex, are conducting trials of planting at different distances.

ROYAL BOTANIC SOCIETY.—The annual meeting of the Fellows of the Royal Botanic Society was held on Thursday, August 10, in the Society's gardens at Regent's Park, Mr. C. BRINSLEY MARLAY presiding. In proposing the adoption of the sixty-sixth annual report, the Chairman referred to the fact that by a vigorous issue of pamphlets, &c., an attack had been made upon the gardens and their administration. He said that he had seen the Society in its decline and in its prosperity, which he believed was rising at the present moment. The Council had wisely declined to give up the scientific part of the Society's work, and the gardens were never in a better condition than they were now. Much useful work had been done, and many societies had availed themselves of the opportunity of meeting in the gardens during the year. It was proposed that the annual subscription of the Fellows should be raised, as this increase would meet their difficulties. He hoped to announce at a meeting on November 27 that the Fellows had agreed to this. During the months of June and July 72,000 persons had visited the gardens, which spoke well for their popularity. The report having been adopted, Mr. J. S. RUBINSTEIN said that he desired to propose a resolution that the statutes and by-laws required revision, to secure rights for the Fellows and making certain recommendations. He expressed an opinion that the subscriptions should not be raised, but that a Committee of Fellows should be appointed to consider the position and confer with the Council. The Chairman said that the Council had decided that Mr. RUBINSTEIN'S letter and recommendations should be read, but that the resolutions be not submitted or voted upon, having regard to their nature as affecting the charter and lease of the Society. The Duke of TECK was re-elected President; Mr. G. J. MARJORIBANKS, Treasurer, and eight Fellows were elected on the Council.

"BRITISH TREES."—The second part of this publication, prepared by Mr. REX VICAT COLE, has been issued by HUTCHINSON & Co. It deals with the Beech and the wild Plum or Sloe, and is marked by the same excellences as those on which we commented on a former occasion, the chief of which is fidelity to nature.

VIEW IN THE STATE NURSERY, CAIRNS, QUEENSLAND.

"BOTANICAL MAGAZINE."—The August number contains coloured illustrations of the following plants:—

Mecynopsis integrifolia, Franchet, t. 8027.—The noble Tibetan Poppy, introduced by Mr. Wilson to the Veitchian nurseries. See *Gardeners' Chronicle* (1904), vol. ii., p. 240, with Supplement.

Tetralthea thymifolia, Smith, t. 8028.—A pretty, greenhouse, hardwooded shrub from East Australia, with wiry stems, small ovate, hirsute, verticillate leaves, and rosy-lilac flowers.

Impatiens Holstii, Engler, t. 8029.—See *Gardeners' Chronicle*, 1905, p. 14, with illustration. Differs from *I. Sultanii* in its broader leaves and reddish-coloured flowers.

Plectranthus crassus, N. E. Brown, t. 8030.—See *Gardeners' Chronicle* (1904), i., p. 21.

Odonoglossum ramulosum, Lindley, t. 8031.—A Columbian species, with a loose, branching panicle and numerous small, yellow flowers; the segments marked with dark-brown blotches.

A FRENCH "COUNTRY LIFE."—The publication is announced by MM. HACHETTE ET CIE, of a Revue entitled *La Vie à la Campagne*, which is admittedly inspired by the English periodical *Country Life*. The new paper is to deal with such subjects as its title suggests, and to be of interest to landowners, farmers, agriculturists, horticulturists, and sportsmen, professional and amateur. Illustrations are to accompany letter-press, which is to deal with all rural toils and pleasures.

HYBRID EREMURUS.—A hybrid has been obtained at Verrières by Monsieur PHILIPPE DE VILMORIN between *E. Bungei* and *E. Bungei* reciprocally crossed. The newcomer has been named *E. Isabellinus* ×, and is remarkable for the colour of the flowers (yellow with a rosy flush). The flowers also are intermediate in size between those of the parents. The plants are more robust than their parents, as often happens in hybrids. A Certificate of Merit was awarded to this novelty by the National Horticultural Society of France on July 13 last.

COVENT GARDEN.—Frequenters of the Central Avenue will note the removal of Messrs. DICKSON & Co., the florists, who had been at the south-west corner of the avenue for many years, and who for a long period supplied our market reports so far as flowers are concerned. Messrs. DICKSON have removed to the West End, and their premises are to be occupied in future by Mr. GARCIA, the select quality of whose flowers and the elegance of whose wreaths and bouquets, as shown in his old premises, must have struck every passer-by.

CHRYSANTHEMUM SHOW IN PARIS.—We have received the regulations and schedule of the Chrysanthemum and Fruit Show to be held at Cours-la-Reine (Paris), from November 4 to 12, by the Société Nationale d'Horticulture de France. In addition to Chrysanthemums, Cyclamen, Carnations, Lilacs, Asters, and general collections of flowering and foliage plants, Orchids and floral arrangements, such as bouquets and sprays, may be entered. Fruit, ornamental trees, vegetables, and works of art more or less representative of plants, flowers, or fruit are available, and there is a special section for machinery. Various awards are offered in the horticultural sections. Intending exhibitors should make immediate application to M. le Président, Rue de Grenelle, 84, Paris.

THE FLORA OF FRANCE.—The third volume of the Abbé COSTE'S *Flore de France* is approaching completion. The last-issued part contains the Lilies, Irises, and Orchids (in part). The description of each species is accompanied by a small woodcut illustration. The work is published by KLINCKSIECK, of Paris, and may be had of Messrs. WILLIAMS & NORWICH.

OVERSEA SUPPLIES: JULY.—The Bank Holiday interfered with the publication of the *Trade and Navigation Returns* for July, but the figures issued made ample amends for the delay; for once again the record has been broken; both imports and exports have gone up with a bound. The IMPORTS for the month are valued at some £44,741,838; this, compared with the total for July, 1900, £40,956,601, shows a "plus" equal to £3,785,237. The increase is mainly in food supplies and raw material for manufacturers. The Wheat and flour supplies from the United States and Canada are on a diminutive scale, owing probably to the Colony being engaged in feeding the Republic; the "foreigner" made up for all deficiencies, and the British miller reaped an advantage. The EXPORT totals make up £27,821,051, against £24,783,552—a difference in favour of the past month of £3,037,499, and this gain is made up of increments in the staple industries—another excellent feature. Respecting fruit and vegetable imports, the following summary table will be found of interest:—

IMPORTS—JULY.	1904.	1905.	Difference.
Fruits, raw—			
Apples	38,413	24,589	—13,824
Apricots and Peaches	19,182	35,405	+16,223
Cherries	74,892	61,340	—13,452
Currants	105,529	76,663	—28,866
Gooseberries	6,274	3,712	—2,562
Grapes	35,196	28,358	—6,838
Pears	49,357	22,813	—26,544
Plums	236,704	138,994	—97,710
Strawberries	4,331	2,975	—1,356
Vegetables, raw—			
Onionsbush.	56,257	59,303	+3,046
Potatosewt.	235,109	217,615	—17,494
Tomatos	158,400	122,153	—36,247
Gross total, including varieties of fruits and vegetables not enumerated in this Table	1,443,599	1,204,694	—238,905

It will interest all who have connections with the Far East to learn that our latest "acquisition" in China, Wei-hai-wei, is about to enter the field as a fruit-producing colony on a large scale. It has all the soil and climatal advantages of Chefoo in the same province, and a large variety of fruit-trees have been ordered from home. The Botanical Superintendent at Hong-kong will, it is stated, have the guiding hand in this new venture, which promises to become a principal feeder to the Shanghai market. Our Normandy friends are reported to be suffering from a very short harvest of cider Apples and table fruits; some of the coarser varieties of fruit make a better show. It may be worth noting that the over-sea supplies for the past month furnish a total of £72,562,889.

THE ESTATE NURSERY.—Most landowners are to some extent aware of the value of a small home-nursery, but few realise the greatness of the advantages which may accrue on any estate, large or small, from the setting apart of a sufficient area for the propagation and rearing of forest-trees and hedge plants, and of a similar provision for a trial-ground, fruit-plot or experiment station. Proprietors are as a class too much addicted to rely on the experience of other people, gained it may be under different conditions and with only indirect reference to the requirements of particular cases. To such persons we commend Mr. SIMPSON'S little treatise bearing the title at the head of this notice. The book may be had from the Country Gentlemen's Association, 2, Waterloo Place, Pall Mall. It deals with the formation of the nursery, the acquisition of seed, the methods of sowing and transplanting, and the general management of

the nursery. These are details in which the advice of the gardener might profitably be sought, and indeed when there is a good understanding between gardener and forester, the gardener might well be entrusted with the management of the seed and seed-beds, and the details of layering. In any case forester or gardener will find numerous practical hints clearly presented in Mr. SIMPSON'S little book.

"FLORA AND SYLVA."—The July number of this attractive publication contains a valuable article on the Pampas grasses (*Cortaderia*), by Dr. STAFF. Five species are described—*C. argentea*, *C. araucana*, *C. speciosa*, *C. rudiuscula*, and *C. Quila*. The "Pampas" grass, it appears, is not characteristic of the Pampas, but occurs in S. Brazil and Paraguay, and in the Argentine. Vast plantations of it have been made in California, where at Sta. Barbara in 1889 the crop was estimated at 1,000,000 plumes. Mr. GUMBLETON adds a note relating to *C. Quila*, the most beautiful of the genus, but unfortunately tender. The name *Cortaderia* perpetuates the native name "Cortaderia," by which the Pampas grass and its allies are known in S. America. A translation in abstract, from M. LEMOINE'S *Monograph on Deutzia*, is of permanent value.

HYBRID NICOTIANAS.—The appearance of the wonderful hybrid *Nicotianas* raised by Messrs. SANDER & SONS between *N. Forgeti* and *N. affinis*, and known as *N. Sanderæ* ×, has stimulated others to make further essays in the same direction. Thus we find that Messrs. CAYEUX ET LECLERC, of Paris, have obtained a Certificate of Merit from the National Horticultural Society of France for a hybrid raised from *N. affinis* by pollen of *N. Sanderæ*. The flowers are described as "enormous," varying in colour from white to rose, lilac, and reddish-violet. The plant is described as very vigorous, and the flowers very fragrant.

FRUIT - GROWING IN BRITISH COLUMBIA.—We heard something of this recently at the Royal Horticultural Society, and now we find, in the *Canadian Horticulturist*, that the province is progressing very rapidly in the matter of fruit-growing. Our contemporary attributes this advance to the fact that many of the fruit-growers have gone into this province "totally unacquainted with fruit-growing, having, however, considerable capital. These men are not loaded down with a quarter of a century of prejudice, but come to their work fresh and willing to imbibe the latest and best from books and from their most successful competitors in the business. This will account for the fact that, on the average, the methods of British Columbia are infinitely ahead of those of the average fruit-grower in Eastern Canada." A quarter of a century of prejudice would seem very moderate in the Old Country, but by way of compensation we may set down centuries of experience. It is for the coming generation to adjust the balance.

PLANT PORTRAITS.

ACACIA PODYALIFOLIA, A. CUNNINGHAM.—Phyllodes ovate acute; flowers in glabular heads arranged in loose racemes. *Gartenflora*, August.

ZYGONISIA ROSEANA.—The result of a bigenerie from *Aganisia lepidia* crossed with the pollen of *Zygopetalum maxillare*. *Flora and Sylva*, July.

DAFFODILS Lord Kitchener, Dewdrop, Fawn, and Sunbeam. *Flora and Sylva*, July.

ANDROMEDA SPECIOSA.—*Revue de l'Horticulture Belge*, August.

ROSE SOLEIL D'OR.—A cross between Persian Yellow and Antoine Ducher. It has the vigorous habit of the former, with the "perpetual" blooming tendencies of the H.P. Flowers full yellow. *Revue de l'Horticulture Belge*, August.

DIANTHUS "WARLEY."—*Garden*, August 5. A seedling raised by Miss Willmott from *Cyclops*, with brilliant crimson flowers.

BATTERSEA PARK.

THE outlying parts of south-western London enjoy in their parks and open spaces a more enviable position as compared with any other, excepting, perhaps, those districts abutting on the breezy northern heights, from which, however, the advantage of a great river in the vicinity is missing. There are the great commons of Wimbledon, Wandsworth, and Clapham, situated at considerable height above the Thames, and open to every wind that blows, and so far but little marred by the landscape gardener. Wimbledon Common is practically in the same natural state that it has been in for hundreds of years, and the others contain but few marks of the improver's hands, if we omit the levelling of the turf and clearing away of the too-abundant Gorse and Brambles.

The park at Battersea differs from the above-mentioned commons in that it is almost entirely the work of the landscape gardener. It is not yet fifty years since it was laid out as we see it, although to most persons, judging from the size of the timber-trees with which its avenues and larger effects are produced, it must seem to be much older. Much of it is "made ground," the site being low-lying and marshy, and at high tides it was, at one time, subject to flooding. This has been averted by throwing up a wide embankment on the river-front, and facing it with rough masonry—the first step in the reclamation of the land. It is owing to the dampness of the soil, to its situation, and to its depth, that trees, shrubs, and herbaceous perennial plants grow with so much vigour. The severest droughts seem to have but small effect on vegetation here.

A visit paid in the present month revealed all the best features of the park; the trees presenting their liveliest tints of green peculiar to each, and the beds and borders of flowering plants were in great beauty, whilst the up-keep of lawns, walks, roads, &c., left nothing to be desired. The area seems to fall naturally into four fairly distinct sections; there is the river frontage, consisting of what is now a fine avenue of Oriental Planes and stretches of rather roughly-kept lawn; then the broad carriage road with a path for pedestrians on the side furthest from the river, beyond which stretch shrubberies bordered with flowering plants, separate parterres of bedding or foliage plants; and shrubberies that contain many striking examples of flowering trees and evergreens. Beyond this portion and the lake are immense lawns devoted to games and promenading; there also is a fine avenue of Elms backed by close plantations of common shrubs—mostly evergreens; and beyond this avenue are other lawns, smaller than those first named; and still further afield is the sub-tropical garden, the great attraction of the park; and the lake, around which many of the finest and choicest trees and shrubs of the park are to be found.

The south side of the park has many fine views of the lake and surrounding bosquets and plantations, and is adorned with numerous specimens of exotic trees and shrubs planted singly or standing in the foregrounds of the shrubberies bordering the lake, while others stand singly on the smooth turf that runs on the south side of a broad road intended for pedestrians only. This road leads in a devious line to the main south-eastern entrance in the Queen's Road.

The visitor entering by this gate and walking in a south-westerly direction will note first a large oblong bed, 30 yards long and 10 wide, planted with single-flowered Hollyhocks in great variety and standing about 2 yards apart, the intervening spaces being filled with show, fancy, and Cactus Dahlias, and vigorous bush Roses, clumps of Phloxes of the decussata section, Pentstemons, and Gladiolus brenchleyensis. The margin of this immense flower-bed is planted with oblong groups of scarlet and pink Pelargoniums, East Lothian

Stocks, white Marguerites, and variegated Pelargoniums forming the edging. There are flanking borders to this bed, similarly treated as regards the materials employed.

Among the trees observed along this road may be mentioned *Koeleruteria paniculata*, possessing numerous panicles of bloom; many fine *Cratægus*, including *C. Aronia*, *C. coccinea*, *C. Crus-galli*, *C. orientalis*, and varieties of *C. oxyacantha*; Tamarisks in variety, well furnished with their pink inflorescences; *Cotoneaster frigida* in fruit; *Pyrus Sorbus*, several species of *Taxus*, and the Stagshorn Sumach. Interspersed are beds of *Cannas* with red or green leaves. There is observed on one side of the road running eastwards from the Albert Road entrance a sunken panel-garden, the beds being planted in pairs, with *Heliotrope* mixed with pink *Fuchsias*, and bordered with *Begonia floribunda*. Two other beds are planted with *Fuchsias*, two with red-flowered *Cannas* and scarlet *Pelargoniums*, with blue-flowered *Lobelia*; two with green-leaved *Cannas*, one having pink and the other scarlet flowers; while the centre bed is filled with *Abutilon Thompsoni* and *Perilla nankinensis* mixed indiscriminately. Next follows a line of a pink-flowered *Nosegay Pelargonium*, and finally an edging of blue *Lobelia*. The entire panel had a margin of beds of *Pelargonium* in variety. Small *Dracænas*, Bamboos, and scarlet *Pelargoniums* are dotted about on the turf, the effect being not quite satisfactory.

Hereabouts were noticed some splendid pyramidal Hollies and a *Gymnocladus canadensis*, the latter much crowded by other and commoner things. Facing this tree and across the road one notices a *Catalpa syringifolia* 30 feet high and proportionately broad. The border of shrubs for many yards is planted, in the front, with *Anemone japonica*, *Calceolaria floribunda*, &c., and edged with *Poa trivialis variegata*. In this part much use is made of species of *Helianthus* with single flowers. Further along this road the border of the shrubbery is furnished with double-flowered Hollyhocks of good quality, beautiful Phloxes in variety, dwarf-growing *Helianthus*, and yellow-and-purple *Violas*.

There are a few good beds observed around the refreshment-house—viz., two with double-flowered *Fuchsias*, and bordered with a broad band of *Thunbergia aurantiaca*, the latter flowering remarkably well. Other beds are planted with *Pelargoniums*, and a border running round the rear of the beds is filled with groups of *Pentstemons*, *Marguerites*, zonal and Ivy-leaved *Pelargoniums*; golden-leaved *Privet* is employed in standard form to break the monotony of the flat surface.

THE LAKE-SIDE AND SUB-TROPICAL GARDEN.

In the approach to this from the east, some capital specimen Hollies may be noticed, and variegated Hollies of small sizes planted in groups with wide glades of grass between. Planted on the margin of the water in various places, *Eulalia japonica zebrina*, *Gunnera scabra*, *Arundinaria Simoni*, *Arundo conspicua*, *Bambusa palmata*; *Iris* of sorts, *Polygonum*, *Fatsia Sieboldi*, *Cortaderia argentea*, several *Vitis*, including *V. Coignetia*, and *Aristolochia Siphon* are employed to break the smoothness of the banks in places.

The usual arrangement of plants in pots, viz., Ferns, Palms, Cycads, *Philodendron pertusum* (*Monstera*), under tall *Poplars*, is still carried out, and the various plants seem more healthy than in former years. One grassy mound is planted with *Livistona borbonica*, at several yards apart.

A bed in the subtropical part, 30 feet long, is exceedingly choice; it is planted with *Solanum jasminoides*, the specimens being 6 feet in height, with a groundwork consisting of a rose-coloured Ivy-leaved *Pelargonium*, to which there is an edging of *Sedum tabuleforme*, *Lobelia*, variegated *Pelargonium*, and *Heliotrope*. It almost seems as if edging-plants generally are too

redundant, and in this case certainly it is so. It is an instance of not seeing the wood because of the trees.

There are also beds filled with some dwarf growing *Cannas* having flowers of vivid colours, with East Lothian Stocks and zonal *Pelargoniums*. Near by, as a foil to all this bright colouring, is a round bed planted with *Chrysanthemum maximum* (single white flowers), underneath which is a pale-leaved *Pelargonium*, on which no flowers are allowed to remain, and masses of pale purple *Violas*, with a variety of *Begonia floribunda* and *Arabis alba* as edging plants in separate lines.

A bed forming a telling combination of plants and colouring is filled with *Fuchsias* of one red variety, *Abutilon Sellowianum marmoratum*, and white-flowered Stocks. Alongside of this is a bed filled with a bronzy-leaved *Canna*, 3 feet high; having an inner edging of *Centaurea candidissima*, and an outer one of Golden *Fleece Fuchsia*, with the shoots pegged to the soil so as to form a flat band, a barbarism perhaps, but yet effective.

There are beds consisting of tall *Fuchsias*, including *F. fulgens*, *Hibiscus Rosa sinensis*, *Plumbago capensis*, *Cassia corymbosa*, &c.; *Grevillea rosmarinifolia* and *Dracæna australis* with *Harrison's Musk* as a carpet; of *Lantana Drap d'Or* and pink and white *Begonias*, with standards of *Acacia lophantha*, and one of *Solanum robustum*, 3 to 4 feet high, associated with red-flowered *Fuchsias* and white-flowered Stocks, forms a striking bed. The finest bed in the garden faces this last, and consists chiefly of standard plants of *Plumbago*, standing on an undergrowth of blue and yellow *Violas*, of *Coleus*, *Heliotropes*, *Abutilon Thompsoni*, with outer lines of *Iresine* and *Pelargoniums*. The next bed to this, one filled with an imposing-looking foliage plant (*Polymnia*), and planted at the sides with purple and white-flowered *Phloxes*, forms a grand sight, the latter plants being at their best, and this year they are as fine as possible.

A large bed of succulents contains many good plants, especially *Agaves*. Hereabouts are more *Fuchsias*, some alone, others associated with *Plumbago capensis* and other plants. Good use is made of *Palms* in tubs, these being arranged on the south side of a line of tall *Poplars*, so that they have full sunshine and are yet sheltered from cool winds. There are some capital masses of Bamboos in this part of the garden.

Mr. Rogers, the new Superintendent, is deserving of much commendation for the admirable manner in which he is managing the park. F. M.

THE SPECIES OF DAPHNE.

THE catalogue of M. Maurice de Vilmorin (*Fruticetum Vilmorianum*) contains a list of species of *Daphne* which seems to me to be very complete. For more than twenty years I have collected specimens of this genus, but I have never in any public or private garden found so complete a collection as that here mentioned.

They are plants of slow growth, difficult to increase and liable to injury from transplantation. In moving the Alpine garden we lost all our old plants in spite of the care that was taken not to injure the roots. As to increasing them, grafting is the easiest method, on *D. laureola* for species with evergreen, and on *D. Mezereum* for those with caducous leaves. Budding is however to be preferred as giving sturdier and more vigorous plants. This is effected in August or September under a bell-glass; it is sometimes six months before the callus forms and a year before rootlets emerge.

From a cultivator's standpoint the genus *Daphne* is divisible into two sections:—First, those that succeed in the open-ground; and second, saxatile or rock species. Among the former are:—

BORDER SPECIES.

D. altaica, Pallas, from Altaic Siberia and Chinese Soongaria. Leaves caducous, lanceolate-oblong; flowers white, in clusters two to five, in

small, terminal bonquets, slightly scented; the fruit is a fleshy-red berry.

D. caucasica, Pallas, from the Caucasus, Taurus, and mountain forests of the Ukraine. Differs from the preceding by its longer, sessile, and glaucous leaves that are obtuse and mucronate, and by its larger, greenish-white flowers in fascicles of two to twenty; the calyx is hoary. It is a shrub about 3 feet high. It is also known as *salicifolia* and *euphorbioides*.

D. Sophiae, Kalenitz, grows in wooded regions of the Ural, and differs from *D. altaica* in its leaves, glaucous below, obovate-oblong, mucronate, narrow at the base. The pointed lobes of the calyx are three times shorter than the tube (half the length in *altaica*). It differs also in its slender filiform branches and in its larger corolla. Berries minium, red. It is a rare plant that survives the severe cold in the Linnæa garden in the Pennine Alps, and it flowers abundantly, but ripens its fruits in the shade only.

D. Mezereum, L., from the mountains of Europe and temperate and Northern Asia. Many varieties are cultivated; the Kew Index mentions one

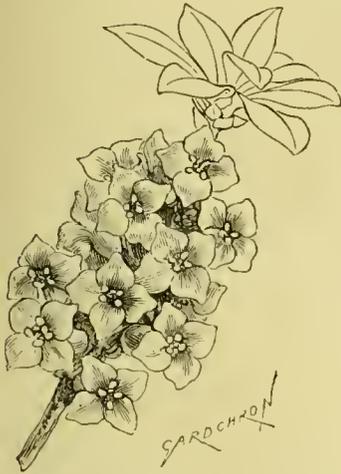

FIG. 52.—FLOWERING SPRAY OF DAPHNE MEZEREUM ALBUM.

with white and one with double flowers, both distributed in gardens; and a third, *grandiflora*, which I do not know, unless it be the same as *alpina*, which I consider as a single form found among the mountains, which reverts to the original in cultivation.

D. Genkwa, Siebold et Zuccarini.—Grown in gardens in Japan, whence it was introduced from China. A curious species, like Lilac in its trusses of mauve blooms, and forming a shrub 3 to 6 feet high, with numerous fine and clustering branches; leaves small, oval-lanceolate, opposite, and with a silky velvety lustre underneath. This is a rare and tender plant, needing a porous non-chalky soil, a partly shaded position, and no damp. The frosts of last January killed all our old plants, and left only the younger ones grafted the previous year.

D. Fortunei, Lindley, from China.—I have not received the plant under this name. An illustration of the species (*D. odora*, *sinensis*, and *Cneorum*) appears in the *Flore des Serres de Van Houtte*, 3, t. 208; flowers lilac, clustered in threes and fours in small lateral subsessile heads; leaves oval-oblong, nearly sessile. The six species enumerated have caducous foliage and bare stems in winter.

D. odora, Thunberg (*D. japonica*), from Japan.—A dwarf shrub, with thick, fleshy branches; thick leaves that seem persistent, green, very glabrous, oval-oblong, pointed; flowers fairly large, pale rose or lilac-white, clustered five to twelve, falling readily, and very odoriferous.

Grown in gardens in Upper Italy, and especially round Lakes Maggiore and Como, where it forms large bushes rarely more than 3 feet high. At Geneva it is frozen in cold winters, but survives if well protected by Fir branches. It prefers whole or partial shade, and flowers in March and April. There is also a pretty variety with leaves bordered with yellow and white.

D. sinensis, Lamarek (*D. indica*, hort.), from the mountains of China.—A shrub growing to 6 or 7 feet, with dark brown branches bearing on the upper parts oval-oblong, glabrous and shining persistent leaves; flowers violet-rose, numerous, in thick terminal clusters, very fragrant. March to May. It does not survive our winters, and requires a cool-house or the conservatory. *D. Delphini*, or *Dauphini* of French horticulture, is apparently the same, as I have always received it under that name, or as *indica* or *sinensis*.

D. japonica, Siebold and Zuccarini.—A Japanese species akin to *D. odora*, but differing in its leaves, narrowed at the base, sub-sessile; in its greenish flowers, borne on a pendulous, pubescent peduncle. I have not grown it, but it is enumerated in the *Fruticetum*.

D. Mazeli, Carrière.—A Japanese species akin to *D. odora*, differing by its flowers, borne on short lateral stems. It flowers in winter.

D. yezoensis, Maximowicz (in *Regel's Gartenflora*, 1866, p. 34).—Not known to me. Grown at Les Barres by M. Maurice de Vilmorin, and is probably near to *japonica*. It is a Japanese species.

D. laureola, L., grows on the wooded, calcareous mountains of central, western, and southern Europe, and in Great Britain. It is a plant of handsome appearance, Laurel-like foliage, with yellowish-green flowers, slightly scented, to which succeed shining black berries. It is grown in woods with good effect.

D. Philippi (*D. pailkesiensis*, Phil.).—From the Pyrenees, differing from *D. laureola* by its bracts, which are larger and longer than the flowers; by its more leafy stems, more bushy, almost trailing habit, and by its smaller, more pointed leaves, with a marked dorsal veining. The flowers are smaller than those of *D. laureola*. Henry Correvon, *Floraire*, (Geneva).

(To be continued.)

A NEW ORCHID DISEASE.*

Just about fifty years ago the late Rev. M. J. Berkeley established in this journal the genus *Hemileia*, which included one species, *H. vastatrix*, the too well-known "Coffee-leaf disease," a parasite that has devastated plantations wherever the cultivation of Coffee has been attempted in the Old World. Two or three other species of *Hemileia* have since been discovered, all parasitic on plants belonging to the Coffee family—*Rubiaceæ*—and all from tropical or sub-tropical regions of the Old World.

Quite recently, however, a fungus parasitic on *Oncidium Cavendishianum*, imported from Guatemala, proved to be a species of *Hemileia* not previously recorded, and a second specimen of the same fungus has also been sent for determination, growing on the leaf of an *Oncidium* that had been growing in this country for some time. The fungus forms bright orange, powdery-looking patches of variable size on the under-surface of the leaf; corresponding areas on the upper surface of the leaf are of a sickly yellowish-green colour. There is never any advantage gained by acting the part of an alarmist; nevertheless, remember-

* *Hemileia americana*, Massee (sp. nov.).—Maculis epiphyllis pallide virescentibus; soris hypophyllis minutis globosis aurantiaco-luteis; uredosporis subglobosis verrucosis 20–25 μ pedicella crasso septato elongato hyalino fultis; teleutosporis obovatis verrucosis apice papilla obtusa ornatiss 30 x 22–25 μ .

ing the terrible havoc caused by the *Hemileia* parasitic on Coffee, it is just as well that cultivators of Orchids should be cognisant of the fact that a very close ally of the Coffee disease has established itself on Orchids in this country. Prompt destruction of every leaf showing the symptoms indicated above should prevent the pest from spreading and assuming the proportions of an irresistible epidemic.

In describing the genus *Hemileia*, Berkeley attached some importance to the arrangement of the markings present on the surface of the

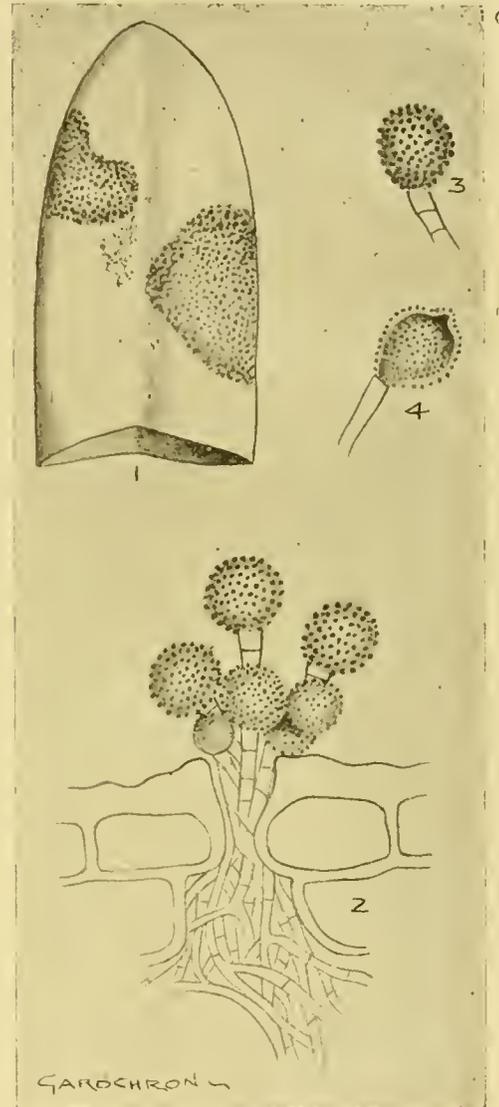

FIG. 53.—HEMILEIA ON ORCHID LEAF.

1. Fungus on leaf; natural size.
2. Section showing hyphae and threads passing through a stoma and producing uredospores; mag. 400.
3. Uredospore; mag. 400.
4. Teleutospore; mag. 400.

uredospores. In *H. vastatrix* the head of spores is densely crowded, and the surface of spores in contact with each other is smooth, whereas the free portions of the surface are coarsely warted, hence the generic name [half-smooth]. This character however, as might have been expected, has not proved to be constant, as the species under consideration has the spores evenly warted all over.

The most pronounced characters of the genus are (1) the protrusion of the spore-bearing threads or hyphae through the stomata only, hence the spores are arranged in small clusters on the surface of the leaf, and not produced in dense clusters that burst through the epidermis of the leaf, as in allied genera; (2) the suckers or haustoria are not

specialised, thickened bodies, as in *Puccinia*, &c., but long slender hyphae, as in *Peronospora parasitica*; (3) the teleutospore is one-celled, with an apical germ spore as in *Uromyces*. Germination as in *Puccinia*. The teleutospores are produced in small numbers after most of the uredospores have been dispersed, and originate from the same spawn or mycelium as the latter. *George Massee.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

A NEW FERN PEST.—Mr. S. T. Wright has sent me from Wisley specimens of Fern-fronds attacked by a pest which has hitherto not come under my notice. I recently sent you a note describing how rising Fern-fronds, chiefly of Lady Ferns, were punctured near the uncoiling tip by an insect which laid eggs, which developed into maggots, these then eating their way down the main rachis to the caudex, and, as I presumed, burying themselves in the soil, to appear the next season either as flies or beetles, the perfect form of the insect being then unknown to me. When fully grown these maggots are of a pale bluish tint. Mr. Wright's examples differ from this in the fact that the fronds sent are fully-matured as uninjured ones, but then a few inches up from the caudex the Fern-rachis shows a round hole about the twelfth of an inch in diameter, from which exudes a white froth resembling that of the immature cuckoo-spit. On splitting the rachis, one and sometimes two creamy-white maggots are found at a short distance below the perforation; and though these are larger and fatter than those previously described as having devoured the whole of the rachis-core, but little of the core is eaten, the inference being that they live on the sap, the froth being their exuviae. The specimens sent are also *Athyria*; but while the presence of the maggots described by me in the first place involves at the outset the perishing of the frond-tip from the point where the eggs were laid, and the subsequent destruction of the rest of the frond as the maggots descend; in those sent by Mr. Wright the frond retains its verdure to a large extent, and is, as I have said, attacked near the base instead of near its apex. Furthermore, this occurs much later in the season, when the fronds are mature, instead of when they are rising. It therefore seems clear that two distinct insects are concerned, of neither of which the life-history seems to be known. The difficulty in both cases is that the severance of the fronds concerned means the destruction of the maggot, due to food deprivation, and hence living plants are required in order to follow out the life-history, and determine the nature of the fly or beetle which lays the eggs. In my own case I have never seen this, though many fronds are destroyed each season. It is to be hoped that some entomologist will take the matter up, in which case both Mr. Wright and myself would be happy to facilitate research by supplying material. *Chos. T. Druery, V.M.H., F.L.S.*

THE DOUGLAS FIR AT SCONE.—"A. P." should know most on this subject, but if his statements this week are correct, they are a puzzling contradiction of the original statements in the *Perth Constitutional*, which were copied into either the *Gardeners' Chronicle* or *Garden* and never contradicted. I write from memory, but I believe correctly, when I say that it was stated, on Mr. McCorquodale's authority, that the Douglas Firs in question were planted, tended, felled, and finally sold by him at 1s. per foot, which must have produced a sum far in excess of "A. P.'s" figure of £34. As "A. P." has not seen the original article in the Dundee paper, may I suggest that he has probably made some mistake. From what I have seen and read of the Taimont wood, I understand that the Douglas Firs were originally planted 12 feet apart, or 302 to the acre (not 202, as stated by Schlich—by mistake), and were filled in with Larch and Spruce to some 4 feet over all. The Douglas have never been regularly thinned I understand, but the Larch and Spruce were cut out, as they

were being smothered, and from what I saw of them they were not worth more, I should think, than £34. Are these the trees "A. P." speaks of, and has he confounded them with the Douglas? If not, then the original account was very misleading, though vouched for at the time and written with the full knowledge of all concerned. As to Mr. Booth's statements, I fear he writes from very loose data, as, for example, when he states (p. 105) that the trees were sold by auction at delivery price. Who ever heard of trees being sold at delivery price when the auctioneer did not know where they were going to? The delivery price is what the consumer pays when the trees are delivered in his yard after the auctioneer's price has been paid. Were Mr. McCorquodale's trees got from another plantation than the Taimont? *J. Simpson.*

RED CURRANTS.—On p. 96 of the *Gardeners' Chronicle*, "A. D.," in writing of these fruits, mentions the variety Comet as being identical with Fay's Prolific, and gives as his authority Messrs. Bunyard. If Messrs. Bunyard have found it to be so, I have not. We have Fay's Prolific obtained from Messrs. Veitch, and the variety Comet bought from Messrs. Laxton, and it would require a lively imagination to describe them as the same variety. The Bedford firm state in their catalogue that it was given an Award of Merit by the Royal Horticultural Society, and it appears to deserve it, but if it is the same as Fay's Prolific, why was this done? Comet with me is the most prolific and earliest fruiter among Red Currants that I am acquainted with. The bunches are more like bunches of Grapes, while two-year-old bushes fruit freely, which I have not found other varieties do. *T. H. Slade.*

OAK-TREES AT STUTTGART.—In answer to a correspondent who applied to us for information on this subject, Mr. Pfützer obligingly writes:—"We have enormous forests of Oak-trees in the vicinity of Stuttgart. The Oak-trees are mixed with some Beech-trees. Our Oaks, *Quercus Robur*, are growing very nicely, much taller than they do in England. They are growing about 20 to 30 yards high; some giants are even taller. We had and have still trees here in Württemberg stated to be 700 to 800 years of age, and these trees have a stem girth of from 8 to 10 yards. The common trees of 10 to 20 yards in height are about 2 to 4 yards in circumference, and the branches near the ground are smaller, so that the form of the tree appears tall, save in some exceptions." *W. Pfützer, Stuttgart.*

EXHIBITING SWEET PEAS.—In my experience as a competitor, official, and judge, I find that nearly all show schedules are quite explicit and definite in their rules [!]; I have also found that all exhibitors are not quite so absent-minded as Mr. B. supposes. All rules are made for a purpose, and that is to put all exhibitors on the same footing, so that one may not have an undue advantage over another. No doubt some rules may be rather stringent, and in stating a definite number of sprays or spikes in a stand, I think the Society makes a mistake; a rule having a fixed number is not elastic enough, and generally leads to ill-feeling, if not to a loss of entries. In a Society of which I am an office-bearer, the rule regarding Sweet Peas is stated as follows:—"So many vases, distinct varieties, not exceeding thirty spikes in a vase. This permits of any number less than thirty, but any more, even one spike, should disqualify. The exhibitor who puts in less than the number allowed is handicapping himself to that extent; and the exhibitor who puts in more, in my experience, generally does so to improve his stand, on the off-chance of not being detected. I hold that when an exhibitor has staged his exhibit, neither an official nor a judge has any right to alter it in any way. How are they to know that a deviation from rule is an oversight? What right have they to say this should come out, and that remain? The exhibitor should know what he means, and no one else has a right to alter his meaning. I remember a show wherein was a class for a collection of six kinds of fruit. A competitor had bunches of black and white Grapes, and five other fruits. The judges, before judging, drew the attention of an official

to it, and he removed one dish, but unfortunately it happened to be the strongest dish in the collection. Rules are not made to be broken, but to be acted up to, and any one who breaks a rule, either through ignorance or intention, should suffer. Those who conform should be protected. This principle runs through all laws. I heartily agree with the Editor in his opinion that where an exhibit is especially good, but does not exactly conform to the rule applying to it, a special award should be given it. I must also differ from "Mr. B." in his remarks that a rule should be made to pass over those with "two and sometimes only one bloom on a spray." He would like three, and if possible four. So should I if I could get them good. But my experience is that generally four blooms on a spray are not good, and I would rather have two good ones than four bad ones. It is far better to leave it open. Exhibitors will never put in two if they can get three or four that are good, but you will limit the competition and keep out some of the very best blooms if you adopt a restrictive policy. I regret to differ from such a good judge as "Mr. B.," but I believe he will, after consideration, concede that to carry out his ideas, however well-intentioned, would lead to endless trouble. *Celt.*

STAGING CARNATIONS AND PICOTEES.—Respecting my note which appeared on p. 96, in reference to this subject, I quite recently saw a commendable exhibit of staging the blooms in bunches. The schedule reads thus:—"For the best six bunches of Carnations or Picotees, distinct, not fewer than three blooms to form a bunch." Four exhibitors competed, and the 1st prize collection contained all exhibition blooms of named varieties arranged in vases on long stems, and with a plentiful supply of their own foliage. Nothing could have had a prettier decorative effect; the blooms were handsome, even from a florist's point of view, and could be distinctly seen and appreciated. In future I shall hope to see more competitors in such classes. The way to increase them is to offer more prizes. *E. M.*

EUCRYPHIA PINNATIFOLIA.—This handsome shrub is now in full beauty, and makes a fine and bold show; it has rose-like foliage and large white flowers. I believe it was introduced by Messrs. Veitch from Chili, where it grows among the rocks at the foot of the Cordilleras. The specimen in flower here is about 9 feet 6 inches in height, and is a mass of bloom. The flowers, which spring from the axils of the upper leaves, are about 2½ inches in diameter, each with four pure white spreading petals and numerous stamens, with long filaments terminating in bright yellow anthers. *W. A. Cook, Leonardslee Gardens.* [It was illustrated in the *Gardeners' Chronicle*, August 22, 1891, p. 217. Ed.]

PHLOXES AT CARDIFF SHOW.—Quite the finest display of herbaceous Phloxes in a cut state that I have ever seen was one at the late Cardiff show, arranged by Messrs. Isaac House & Son, The Nurseries, Westbury-on-Trym, Bristol. At the time I thought such a display was of a highly educational character, and deserved a special note, which I now make as a guide to intending planters of this showy, useful, and easily-grown herbaceous plant. There is no doubt the finest selection of sorts can be made from a display of this character much more accurately than from the ordinary trade catalogue, as here it is a question of choosing the colours and forms most admired. Messrs. House grow 20,000 plants in 200 varieties, therefore they have a magnificent opportunity for selection and comparison. On this occasion they staged 100 varieties, of which the following I selected as being desirable:—White Phloxes always command attention, as apart from their beauty they are so useful in floral work; *Fiancée*, *Albatre*, *Mathilde Seroa*, *Sylphide*, and *Esme* are the best varieties of bright rose colour to rosy-salmon included; *Archibald Forbes*, *Comète*, *Le Siècle*, *Miss Pemberton* (especially fine), and *Mrs. Arthur Baker*. Of pink and rose-coloured flowers there were *Béranger*, *Feodora*, and *John Forbes*. The best of the deep blue and violet-coloured sorts were *Emanuel de Rouge*, *Iris*, and *Eclairer*, which is still one of the best of early-flowering Phloxes. The best scarlet and orange-scarlet coloured

varieties were Brilliant, Coquelicot, Etna, John Fraser, Liberté. Mounet Sully is an improved Coquelicot; Suffrage, Tom Welsh, Embarrassment, Roger Marx, very fine; Aurora Borealis, and Adonis. The following flowers were white with a crimson centre:—Jean Jerbaud, extremely showy; and Henry Murger. Of pale blue and mauve colours there were Espérance, Acropole, Crépuscule, Dervische, Lamartine, and Pharaon. The varieties James Farquhar and Madame Neera are of silver-grey colour. Of crimson-purple to deep crimson colours, Ferdinand Cortes, Lord Kelvin, and Walter Wright, a new rich purple flower of excellent form, were the best. *E. Molyneux.*

rich orange-yellow. I will send you a photograph. Apples in England, Ireland, and Scotland are like the old-fashioned Tulips and Daffodils of twenty years since in requiring a thorough overhauling. There are some fine old Apples in this country, superior to any coming from England; I am working them all up again, as I did with the Tulips. *Wm. Baylor Harland, Cork.*

THE CULTIVATION OF SCHIZANTHUS.

For the illustration of Schizanthus (fig. 54) we are indebted to Mr. G. W. Harbron, of Endcliffe

in height, using six stakes to a plant, placing one in the centre and five round the outside of the pot. The compost used for the first and second pottings is composed of good fibrous loam and leaf-mould in the proportion of half each, with sharp sand and charcoal dust. For the final potting I use three parts old Chrysanthemum-soil to one of leaf-mould, with some sharp sand and a good dressing of charcoal dust, the Chrysanthemum-soil being, I find, sufficiently rich without requiring manure. When the pots are filled with roots I feed well with manure-water. The plants require very careful watering, for should the soil become too wet they damp off very quickly. The varieties I grow are as follows:—*S. pinnatus*, *S. p. candidissimus*, *S. p. roseus compactus*, *S. grandiflorus oculatus*, *S. papilionaceus pyramidalis*, *S. grandiflorus pyramidalis compactus*, *S. Grahami carmineus*. *G. W. Harbron, The Gardens, Endcliffe Grange, Sheffield.*"

FORESTRY.

THE LOCUST TREE.

"A. P.," in your issue of August 12, makes the broad statement that it is the proved worthlessness of the timber of this tree as a forest tree in this country that is accountable for its neglect. If "A. P." would give some statistics and details to prove his statement I should be much obliged. Meanwhile, our position here is as follows:—Lurch-disease has made such strides in the last two years that plantations of Larch twenty years old and more, which were perfectly healthy two years ago, are this year dying by hundreds. Smoke and caterpillars are killing the Oaks. Spanish Chestnut is so far doing well, and is the only tree left of first-class timber for rough estate purposes, such as fencing, &c.

Our attention was turned to some Locust trees planted in 1862, which had to be cut down. They were about 40 feet high, and contained 19 feet 6 inches of timber below the first branch, in spite of being badly grown, and nearly as broad as high. We made posts for park fencing out of the timber, and the head woodman said the wood was harder than Oak.

There are millions of colliery props sold every year in this country. Mr. Booth says that abroad props made from the Locust tree are more valuable than those made of Oak; it would be interesting to hear "A. P.'s" experience in this direction with the timber of this tree which he considers to be quite worthless. *Basil Levett, Wychnor, Co. Staffs.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and General Summary, ante, pp. 81-87.)
(Continued from p. 137.)

5, SOUTHERN COUNTIES.

BERKSHIRE.—The Apple crop in this locality is generally much below the average, and that of Pears, although the trees developed plenty of bloom, is also below an average crop. Small fruits are abundant. Strawberries were a good crop, for although the earliest-produced trusses of flowers were cut off by frost, the rains benefited the later ones, which furnished a good crop of fruit. Apple-trees have suffered much from American blight. *J. Howard, Benham Park Gardens, Newbury.*

— The general fruit prospects in this neighbourhood up to May 20 were all that could be desired, Apples, which may be considered the principal fruit crop, looking up to that time remarkably well; but after that date 7°, 10°, and 11° of frost appearing caused them to be a complete failure. The same may be said with regard to Plums, except those growing upon walls; but

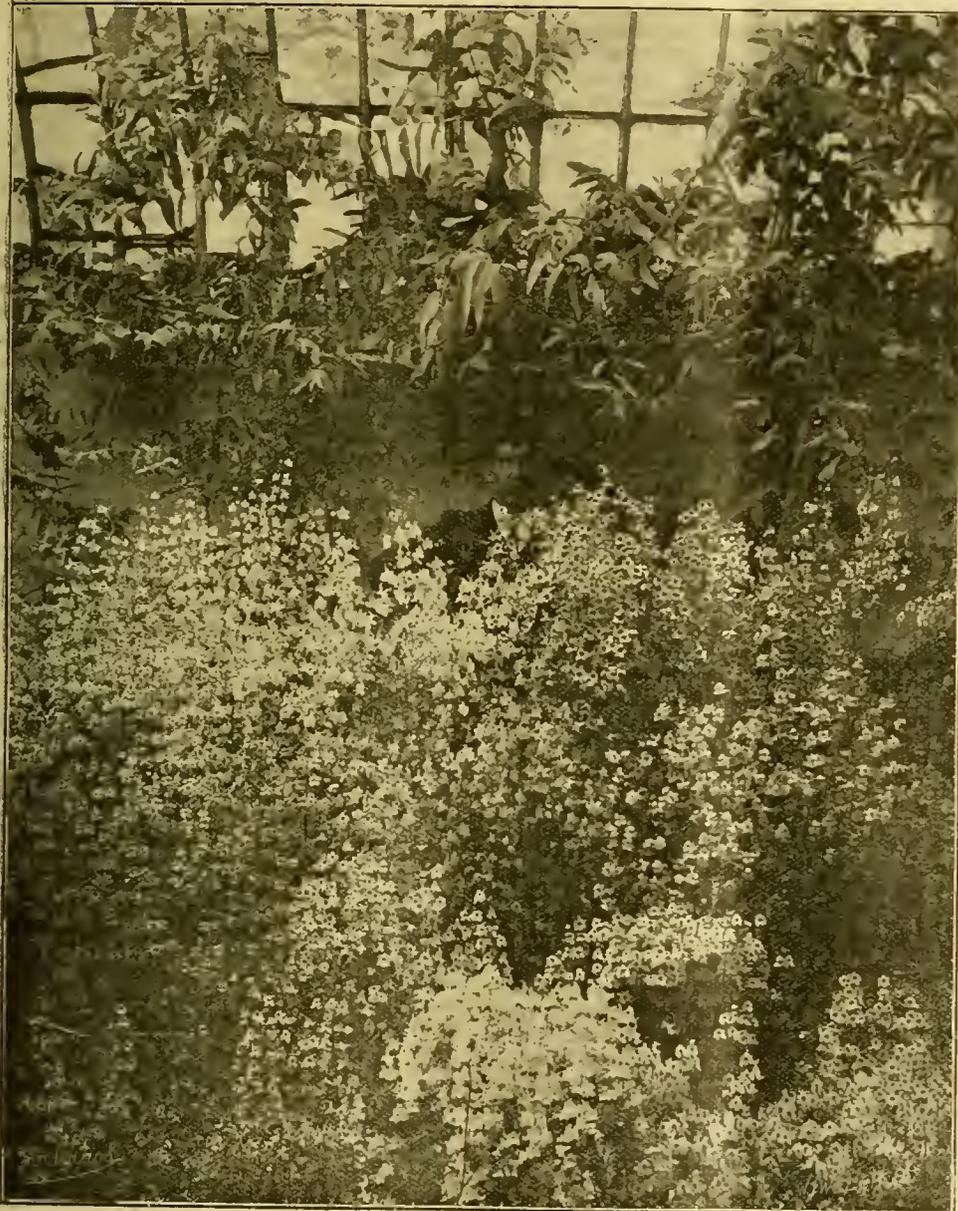

FIG. 54.—SCHIZANTHUS IN THE GARDEN OF C. W. KAYSER, ESQ.

APPLE FIVE-CROWN PIPPIN.—With reference to a note recently published in the *Gardeners' Chronicle*, I was indeed surprised not to have seen this magnificent Apple put at the top of the list as a table fruit. There is a tree here at Ard Cairn planted about fifteen years, and if there is one Apple on the tree there are 1,000. It is superior to any Ribston in substance and quality, and we had it in excellent condition until May 10 this year. About February it is superb. The tree came to me originally from Herefordshire; the name got lost in transit, and therefore I sent specimens of the fruit to the chief nurseries in England, when it was variously named Holland-bury, Gravenstein, Winter Queening, Tom Putt, &c. Its colours vary highly here, and the flesh is of a

Grange Gardens, Sheffield, who sends us the following particulars as to his method of growing the plants:—

"The seed is sown in the second week in August, and the seedlings when large enough to handle are pricked off singly into thumb-pots, and again later into 5-inch pots. The final potting takes place about the middle of February. I use pots ranging from 7 to 11 inches in diameter, according to the vigour of the varieties. I grow them in a temperature of 55°, and at about the end of March they are placed in a conservatory in a group, and allowed to grow together. As to training, I employ stakes ranging from 3 to 6 feet

Peaches and Apricots are above the average. Bush fruit, including Strawberries, are both plentiful and good. *William Fyfe, Lockinge Gardens, Wantage.*

— The soil here varies very much, and includes gravel, clay, and chalk, the subsoil being principally clay. The fruit crops in this garden and in those in the vicinity are rather unsatisfactory this year. The crops of Apples are very sparse, and the same may be said of Pears. Plums, on the contrary, are an immense crop, the trees breaking down with the great quantity of fruit. Gooseberries and Currants have also splendid crops. Strawberries were most unsatisfactory, the finest and best fruits being spoiled by the rains during the latter part of June, from which cause more than half the crop rotted on the ground. *James Coombes, Engtefield Gardens, Reading.*

— The fruit crops in this district were quite spoiled by the severe frosts at the end of May. Plums and Pears trained on walls are the more satisfactory, but even these are far from good. Strawberries have been most disappointing, the variety Laxton being by far the best, both in amount of crop and in quality. Laxton's "The Latest" is a first-class late variety, the fruits being large, well coloured, and of splendid flavour. Givon's Late is also worthy of mention, the fruits being large, firm, and of excellent quality. *Wm. Pope, Highclere Gardens, Newbury.*

DORSETSHIRE.—The Apple prospect in orchards is bad, and complaints are general hereabouts of the few fruits that have developed dropping largely. Bush-trained trees in the kitchen-garden, which received attention last season with regard to thinning the crop and were given copious waterings, are again bearing a good average crop; but still the fruit up to the present time is not nearly so healthy in appearance as it was last season. Pear trees with few exceptions, notably Marie Louise, Pitmaston Duchess, and Maréchal de la Cour, are bearing good average crops, and are fairly healthy. Among Plums, Early Prolific, Victoria, and Pond's Seedling are carrying moderate crops, but the choicer dessert kinds are deficient in this respect. Sweet Cherries have been excellent, but Morellos are not so good. Peaches and Nectarines are an average crop, and the trees have recovered wonderfully from a bad attack of "blister" in the spring. The crop of Apricots is again poor. Bush fruits have good crops, while the Raspberry crop is also satisfactory. Flavour in the Strawberries was affected by the excessive heat the third week in June; but late kinds, and especially "Climax," have been more than usually good. *T. Turton, Castle Gardens, Sherborne.*

— The promise of a good fruit season was shattered by the appearance of frost, cold winds, and fog during the latter part of May. The blossom was very clean, and was in some cases fertilised, but the fruits turned black and fell off. The above conditions did not affect the bush fruits, but Plum-trees suffered terribly. Pears also were badly affected, but the variety Doyenné du Comice stood the adverse conditions well. Among Apples the varieties Gloria Mundi, Lord Grosvenor and Duchess of Oldenburgh escaped much injury. The soil in this district is sandy loam, with a subsoil of ironstone. *H. Kempshall, Abbotsbury Castle Gardens, Dorchester.*

— The fruit-crops here would be greatly improved by rain, as the soil is very dry. Most fruit-trees are suffering from a severe attack of blight. Our soil is very chalky and of a dry nature. *Thos. Denny, Down House Gardens, Blandford.*

— The fruit crops are under the average amount in this locality, although all the trees flowered and set their fruits well, but keen, frosty

winds throughout April and during the early part of May caused Pears and Plums to drop wholesale. Apricots, Morello Cherries, and Peaches are carrying fair crops. Plums are but half a crop; while Pears are also sparse. Some varieties of Apples on standard trees in orchards are heavily cropped, but bushes and espaliers are carrying thin crops, although what fruit there is is of good size. Small bush fruits are abundant and of good quality. Strawberries were a light crop and were soon over. Fig-trees are carrying fair crops, especially the variety Brown Turkey. *Ben Campbell, Kingston House Gardens, Dorchester.*

— The fruit crop in our immediate neighbourhood is under the average, owing to the appearance of late frosts. Strawberries in some gardens were a complete failure, whilst in others there was an average crop. Apples suffered greatly, but there is a moderate amount of Pears and Plums. Peaches growing outside suffered much from "blister." Apricots do badly with us; the trees are continually dying. Small fruits—Currants, Gooseberries, and Raspberries—are an average crop. The soil here is heavy clay. *Alfred Coleman, Motcombe, Shaftesbury.*

HAMPSHIRE.—Our fruit-crops are under the average amount all through. Early varieties of Strawberries escaped injury, but Strawberries did not last long in fruit, the late frost damaging the main crop. Gooseberries, Red and Black Currants, and Raspberries are all very good. Damsons are also a good crop, but Plums are very bad. I never saw such a quantity of Filberts and Cobnuts, the trees being laden. The Apple-crop is thin, many fruits having dropped at midseason. Bush-trees that were thinned last season are cropping moderately well. *Arthur Lee, Palace House Gardens, Beaulieu, Brockenhurst.*

— The soil here is a strong loam overlying a heavy tenacious subsoil with chalk below. Apples are an average crop, the trees looking remarkably well, and the fruit swelling rapidly. Such sterling varieties as Cox's Orange Pippin, Allington Pippin, Worcester Pearmain, Lord Grosvenor, Stirling Castle, Branley's Seedling, and Norfolk Beauty, all promise well. Damsons are especially a heavy crop, also wall Cherries. Gooseberries and Currants are heavily laden with good fruit. Strawberries have done remarkably well, especially the varieties Leader, Royal Sovereign, and Sir J. Paxton. *Edwin Motyneux, Swanmore Park, Bishops Waltham.*

— The prospect early in the spring gave promise of a good fruit year, but on the nights of May 21, 22, we experienced disastrous frosts. Apple-trees, notwithstanding their heavy crops last season, gave promise of plenty of fruit again this year; but the hope has not been realised. Strawberries were a mass of blossom, but it was almost all destroyed; while Raspberries and Pears shared the same fate. Currants, both Black and Red, are carrying good crops of fine fruit. Gooseberries, although half the fruit dropped from the frost, are carrying an average crop of fine clean berries. Apricots are a good average crop, as are also Cherries. Our best crop is Plums. The soil is stiff on a clay subsoil, and the situation low, consequently we suffer greatly when late frost appears. *A. G. Nichols, Strathfieldsaye Gardens, Mortimer R.S.O.*

— The soil here is, on the whole, of rather poor quality, with a gravelly clay subsoil. Fruit-trees of all kinds blossomed well, but the sharp frosts in May destroyed the Apple, Plum, and Pear crops in the open. Small fruits did not suffer quite so badly, although the first-formed flowers of Strawberries and Raspberries were largely destroyed. *J. Wasley, Sherfield Manor Gardens, Basingstoke.*

— The fruit crops in this district are about the average, with the exception of Apples and

Pears, which looked very promising until May 23, when we experienced 7° of frost, while in some places as much as 10° were registered, which completely ruined the blossom. Varieties are no exception this time. Plums were well set before the frost came, as were also Peaches. The earliest-formed trusses of Strawberries were destroyed, but there were nevertheless good crops of this fruit, and the same may be said of other small fruits. *J. Bowerman, Hackwood Park Gardens, Basingstoke.*

— But little blossom appeared on our Apple and Pear-trees this season, but what did develop set well. The soil here is a strong loam. *Noah Kneller, Malshanger Park Gardens, Basingstoke.*

(To be continued.)

SOCIETIES.

THE ROYAL HORTICULTURAL.

AUGUST 15.—Although there was much that was interesting at the usual fortnightly meeting of this Society, held in their Hall in Vincent Square, Westminster, on this date, the number of exhibits was below the average, and the attendance meagre. This was to be expected, now that the holiday season is in full swing; nevertheless there were good groups of plants, flowers, and fruit presented, and the Committees found plenty to do in adjudicating upon novelties. Each recommended awards—the ORCHID COMMITTEE one First-class Certificate, the FLORAL COMMITTEE one First-class Certificate and five Awards of Merit, and the FRUIT AND VEGETABLE COMMITTEE several Awards of Merit to produce that had been found worthy after trial in the Society's Gardens at Wisley.

A prominent feature was the display of about 200 choice varieties of Gladioli, staged by Messrs. KELWAY & SONS; another was the excellent exhibit from the gardens of Miss ADAMSON, Regent's Park, who sent a collection of fruit, and another of plants. Many good groups of herbaceous flowers were also displayed.

A paper by Professor H. J. Webber, of the United States Department of Agriculture, was read on the "Progress of Horticulture in the United States," in which he treated of refrigeration, new varieties, hybridisation, methods of culture, and diseases and their remedies.

Floral Committee.

Present: W. Marshall, Esq. (in the Chair), and Messrs. Chas. T. Drury, H. B. May, Geo. Nicholson, John Green, Wm. Cuthbertson, Chas. Dixon, J. T. Bennett-Poë, W. P. Thomson, E. H. Jenkins, W. J. James, James Walker, Herbert Cuthush, John Jennings, Chas. Blick, Wm. Howe, R. C. Notcutt, and E. T. Cook.

Messrs. JAS. VEITCH & SONS, Ltd, King's Road, Chelsea, displayed a batch of the new *Buddleia variabilis* var. *Veitchiana*, and an improved form labelled *B. v. magnifica* (see Awards). The pyramidal spikes of lavender-coloured flowers of these plants made a pleasing show, and were produced in plenty. A row of the coarse-growing *Senecio clivorum*, with baskets of *Ericas* in variety, *Menziesia polifolia atro-purpurea* and small plants of Bamboos in pots completed the group. On an adjacent table Messrs. VEITCH had a batch of *Gloxinias*, and a number of plants of the beautiful blue-flowered *Exacum macranthum*. The *Gloxinias* are worthy of note, for although it is not more than six months since they were sown, they were carrying excellent flowers of large substance, the selection of colours being most noteworthy and representing a most desirable strain (Silver Flora Medal).

Mr. Geo. Kelf, gr. to Miss ADAMSON, South Villa, Regent's Park, is to be congratulated on his excellent group of stove and greenhouse plants displayed on the floor of the Hall. It was arranged in the form of a bank with an undulating foreground. The background was composed of tall Palms, with *Liliums*, *Agapanthus umbellatus*, and *Campanula pyramidalis* at intervals, while *Caladiums*, *Codiaeums* (*Crotons*), *Dieffenbachias*, *Dracenas*, with here and there a taller member, such as *Pandanus Veitchii*, pillar-trained plants of *Cissus discolor*, and *Cocus Weddeliana* formed the main

features, the whole being finished with a suitable edging of *Isolepis gracilis* and *Panicum plicatum* (Silver-gilt Flora Medal).

Messrs. KELWAY & SONS, Langport, Somerset, the well-known Gladiolus specialists, filled the concert platform with a magnificent collection of these flowers, embracing about 200 of the choicest kinds in cultivation. In addition to the better-known varieties, there were a number of new seedlings, two of which received awards. Other quite new kinds are Baron Komura, a large fringed flower of salmon-pink shade; Admiral Caillard, an unique plum-coloured flower; and Terra Nova, with beautiful flesh-coloured petals, the lower one being tinged with yellow (Silver-gilt Flora Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, put up a showy group of bedding and border flowers, including Asters, Antirrhinums, Salpiglossis, Delphiniums, *Calliopsis tinctoria*, *Lavatera trimestris*, *Centaurea moschata*, *Scabiosa grandiflora*, and others. The Asters were a remarkably fine lot, while a basket of Antirrhinums named Defiance was splendid in effect, the colour being a rich orange-red, with a lighter throat to the flower. Dwarf forms of *Nemesia strumosa* found a place in the collection, and on the floor opposite was a group of the graceful foliage plant *Kochia scoparia*, set off by dark-foliaged Cannas and sprays of Bamboos at the background (Silver Flora Medal).

Messrs. WM. ARTINDALE & SON, Nether Green Nurseries, Ranmoor, Sheffield, showed a grand collection of herbaceous flowers, Phloxes, Gladioli, Pentstemons, Coreopsis, Heleniums, Harpaliums, Scabiosas, and a host of other seasonable flowers, all in the best possible condition. A stand of *Violas* occupied the centre of the display, these being staged in a less formal manner than they are usually shown. Some good border Carnations also found a place in this collection (Silver Flora Medal).

Mr. AMOS PERRY, Winchmore Hill, London, N., put up a large group of hardy flowers, all showing excellence of culture, and embracing most of the best subjects now in season. *Bravoa geminiflora* was noticed in flower, also fruiting sprays of *Rubus sorbifolius*. Other interesting plants were *Cedronella cana*, *Buddleia variabilis*, *Rudbeckia fulgida variabilis*, and *Asclepias cinerea* (Silver Banksian Medal).

Messrs. BARR & SONS, King Street, Covent Garden, London, displayed a number of herbaceous flowers, including many of the best now in season. Some spikes of Gladioli occupied the centre of the group. Several good hybrid forms of *Lobelia cardinalis* × *syphilitica* were noticed.

Messrs. GUNN & SONS, Brookfield Nurseries, Olton, showed seventy varieties of herbaceous Phloxes.

Mr. R. E. SANDERS, Halton Gardens, Tring, showed two variegated-leaved forms of *Phlox decussata*. One labelled Comte de Jarnol was of a silver-leaved type, the other was a golden form, and labelled President Kruger.

The waning of the season was evidenced by several displays of Dahlias. Messrs. JOHN STREDWICK & SON, Silverhill Park, St. Leonards, staged ten new varieties of Cactus-shaped flowers, two of which will be found described under Awards. Among the others, Twilight is a good medium-sized flower with well-shaped petals, the centre ones of which are of a lemon-yellow colour, the older being a very delicate blush-rose. Primrose is a good yellow-coloured flower.

Mr. S. MORTIMER, Rowledge, Farnham, Surrey, showed an excellent collection of Dahlias, having both the Cactus and the show type of flowers. All the latter and some of the former were displayed on exhibition boxes on either side of a central group that was composed wholly of Cactus varieties. Several new unnamed seedlings were included, many of great promise. One of the "show" type, somewhat after the style of Mrs. Langtry, appealed to us; it is a flower of large substance and of excellent colour. Pink Perfection and Alice (light scarlet) are other good varieties (Silver Banksian Medal).

Mr. H. SHOESMITH, Westfield, Woking, brought four new varieties of Cactus Dahlias, the best being a scarlet-coloured variety named W. Collins.

Messrs. HUGH LOW & CO., Bush Hill Park, Enfield, put up a batch of *Chironia ixifera* (see Awards) and pans of *Saxifraga sarmentosa tricolor superba* with well-developed foliage.

Messrs. WM. BULL & SONS, King's Road, Chelsea, displayed a basket of *Hydrangea nivalis*, a variegated-leaved form that received an Award of Merit in September of last year; and a new variety of *Agapanthus* from the Orange River Colony named *A. globosus*, which we shall refer to again.

Messrs. GEO. BUNYARD & CO., Maidstone, presented a hybrid *Eryngium* of slender habit named *E. × Bunyardi*, the parents being *E. Oliverianum × E. Bourgati*.

Mr. J. WHITTON, Superintendent of Parks, Glasgow, showed flowers of the white *Vallota*, figured in the *Gardeners' Chronicle*, August 27, 1904, p. 150.

Lord ROTHSCHILD, Tring Park (gr., Mr. Dye), showed *Nymphaea pulcherrima* Tring Park variety, and *N. zanzibarensis rosea*.

A flowering spray of *Oxera pulchella* was displayed by Lady PLOWDEN, Aston Rowant House, Oxon. A full-page illustration of this plant was given on p. 209 of our issue for February 18, 1888.

Messrs. WATKINS & SIMPSON, 12, Tavistock Street, Covent Garden, London, displayed vases containing the beautiful blush-tinted Sweet Pea Gladys Unwin.

Mr. J. EDWARDS, 103, Kempe Road, Kensal Green, W., showed pot plants of a dwarf *Tropaeolum* named Salmon Beauty.

Awards.

Buddleia variabilis magnifica.—This plant was fully described in our issue of the 5th inst. when it received an Award of Merit. The Committee on the present occasion advanced the award to a First-class Certificate. It may be interesting to record that this variety was selected from wild plants in their natural habitat. Shown by Messrs. JAS. VEITCH & SONS.

Gladiolus French Fleet.—The flowers are not over large, but are remarkable on account of the two lower petals of the inner whorl being blotched with dark maroon, the other petals being salmon-coloured. The individual flowers are of a distinct hooded shape (Award of Merit).

G. Peace Envoy.—A large creamy-white-coloured flower, the younger flowers having a lemon-yellow tint, which they lose when fully expanded. The lower petal of the inner whorl has violet markings on a sulphur-coloured ground. A most handsome variety (Award of Merit). Both the above were shown by Messrs. KELWAY & SONS.

Chironia ixifera.—A greenhouse evergreen plant with fine Carnation-like growth terminating in loose cymes of pleasing star-shaped flowers of rosy-pink colour, with prominent yellow stamens. It is of free-flowering habit, and as shown in 48-size pots about 12 to 18 inches in height. A desirable subject for the greenhouse or conservatory staging (Award of Merit). Shown by Messrs. HUGH LOW & CO.

Dahlia (Cactus) T. A. Havemeyer.—A large flower of light crimson colour, with long, quilled petals pleasingly incurved (Award of Merit).

D. (Cactus) William Marshall.—A good-formed flower, with yellow centre shading to cinnamon colour in the older petals, and resembling in many respects the variety J. B. Riding, but lighter in shade (Award of Merit). Both the above were shown by Messrs. STREDWICK & SON.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), H. Little, W. Boxall, G. F. Moore, F. W. Ashton, H. Ballantine, H. T. Pitt, H. A. Tracy, J. Douglas, and De B. Crawshaw.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr., Mr. Alexander), showed the only group staged, and one which creditably represented the Orchid interests in all points, whether in the matter of good culture or fine quality of the species and varieties staged. The central plant was an enormous specimen of *Laelio-Cattleya × elegans*, with eighteen flower-spikes, bearing together one hundred and five fine rose- and -purple flowers, and which secured a Lindley Medal for high cultivation. Another form, *L.-C. × elegans* "King Edward," had large rose-purple flowers, with broad crimson-purple lips. Another pretty form of *L.-C. × elegans* had four spikes, two of them with ten flowers each, and all were in superb condition. As novelties the best were two dissimilar varieties of *Laelio-Cattleya × Berthe Fournier* Westonbirt variety (*L.-C. × elegans × C. Dowiana aurea*), raised at Westonbirt. Both are of a rich rose-purple tint with labellums of a glowing ruby-purple, with gold-coloured lines at the base. One had the side lobes of the labellum extended at the sides, the other more folded over the column, and with the edges wavy. *Laelio-Cattleya × callistoglossa* varieties, *L.-C. × blethleyensis*, *Lelia crispa*, and the fine Westonbirt variety; *Cattleya × mollis*, *C. × Germania magnifica*,

two good specimens of *Cypripedium × Lord Derby*, *C. × A. de Lairesse*, *C. × Maudie*, *C. × Chapmani magnificum*, *Odontoglossum × Harryanum*, several good *O. Uro-Skinneri*, and other good Orchids were also included in the group, for which a Silver-gilt Flora Medal was awarded.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), showed a magnificent plant of *Laelio-Cattleya × elegans Turneri*, with fine strong spikes of twenty-three flowers. The sepals and petals are light rose-purple, the front of the lip and tips of the side lobes dark reddish-purple (Cultural Commendation). Mr. GURNEY FOWLER also showed another form of *L.-C. × elegans*, a pretty form of *Cattleya × Wavriniana* named Fowler's variety, with cream-white sepals and petals tinged with purple, and glowing purple labellum, the base of the front lobe bearing yellow markings on each side indicative of *C. granulosa*, which with *C. Warscewiczii* produced it. Also *Cattleya × Elvina* (*Triana × Schilleriana*).

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Hopkins), showed *Cypripedium × Mrs. Herbert Druce*, a very pretty pure white flower densely spotted with purple; *Cattleya Eldorado magnifica*, a charming form with pale rose-pink flowers with deep orange throat, and very fragrant; and *Cattleya × Atalanta* Westfield variety (*Leopoldi × Warscewiczii*), differing widely from the original, and bearing a general resemblance to a fine form of *Laelio-Cattleya × elegans* in its rich, deep purple labellum.

Messrs. JAS. VEITCH & SONS, Chelsea, showed a fine example of *Cypripedium × Jas. H. Veitch* (*Stonoi platytanium × Curtisii*), and *C. × Numa* var. *nigra* (*Stonoi platytanium × Lawrenceanum*), an improvement on the original form in the nearly black markings of the petals and lines on the whitish ground of the dorsal sepal.

F. M. BURTON, Esq., Highfield, Gainsborough, sent a hybrid *Cypripedium* resembling *C. × Bryan*.

Messrs. HUGH LOW & CO., Enfield, showed *Phalænopsis violacea* Low's variety, several pretty forms of *Odontoglossum Pescatorei* with purple-marked labellums, and some cut Orchids.

Awards.

FIRST-CLASS CERTIFICATE.

Laelio-Cattleya × Berthe Fournier Westonbirt variety, from Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (*L.-C. × elegans × C. Dowiana aurea*).—Raised at Westonbirt, and a great advance on any previously shown, both in form and colour. Sepals and petals rich rose-purple in colour; labellum of a glowing ruby-purple with gold lines at the base, and beautifully-crimped margin.

Fruit Committee.

Present: G. Bunyard, Esq. (Chairman); and Messrs. W. Bates, S. Mortimer, A. Dean, W. Pope, G. Kelf, H. J. Wright, H. Markham, H. Parr, F. Q. Lane, J. Jacques, D. Thomas, A. H. Pearson, and J. Cheal.

Mr. G. KELF, The Gardens, South Villa, Regent's Park, staged a first-rate collection of fruit, specially marked as being grown within 2 miles of Charing Cross. The collection included Grapes, six bunches of Black Hamburg, three of Alnwick Seedling, and six of Buckland Sweetwater, all of good quality; also Peaches, fine Barrington, Princess of Wales, Bellegarde, and the Nectarine; second crop Turkey Figs, Dr. Jules Guyot Pears, Golden Gage, Kirkes, Emperor, and Early Transparent Plums, several Melons, and at one end of the table a fine pot tree of Emperor, and at the other end another of Coe's Golden Drop Plums (Hogg Medal).

Messrs. G. BUNYARD & CO., the Old Nurseries, Maidstone, sent a collection of thirty dishes and baskets of Apples in distinct varieties. Of kitchen varieties, Early Victoria, Pott's Seedling, Ecklinville, Domino, Golden Spire, James Welch, Stirling Castle, Lord Grosvenor, Grenadier, and Lord Suffield were all excellent. Dessert varieties were represented by White Transparent, Cardinal, Lady Sudeley, Beauty of Bath—these three being finely coloured; also Red Quarrenden, Ben's Red, Jas. Grieve, Irish Peach, and others. The collection created the impression that Apples will be seen in fine form in October (Silver-gilt Knightian Medal).

A box of the old and esteemed Peach *Violette Hative*, sent by Mr. R. MONTFORD, of East Sheen, and grown on a tree, the stock stem of which had once been so severely injured that it almost died, received a Silver Knightian Medal as evidence of excellent culture.

Mr. A. HUCKFIELD, Pershore, sent a purplish, round, seedling Plum, of but little merit.

Mr. J. B. COLVILL, of Sidmouth, had picked fruits and clusters of a Raspberry named Red Diamond; the variety seemed to be a good fruiter, the berries being of a good size and of a deep colour. It was not regarded by the Committee as superior to varieties already in commerce.

Mr. D. POWER, The Gardens, Wroxton Abbey, Banbury, sent three Cucumbers named Power's Supreme. The fruits much resembled those from a good stock of the variety Rochford's Market.

Consequent on the inspection, by a deputation from the Committee, at Wisley Gardens on the 8th inst. of a trial of Tomatos of 120 varieties, and another of early and second-early Potatos, several of these fruits received Awards, which see.

Mr. A. VINSON, Belvedere, Kent, sent through Messrs. DOBBIE & SONS examples of the Potatos Factor and Tyne Kidney, of remarkable robustness, as grown by him over 160 acres. The specimens were in luxuriant health. The tuber crop is already a heavy one.

Mr. T. A. SCARLETT, the well-known Edinburgh Potato-grower, brought very large and somewhat deep-eyed examples of the new Dalmeny Radium, also a dish of Southern Star, a long, smooth, handsome kidney, and Russet Queen, a pretty, smooth, round variety. Mr. Scarlett also showed single roots of these varieties, that of Southern Star being remarkably good.

Awards.

FIRST-CLASS CERTIFICATE.

Peach "Violette Hâtive."—This well-known and old variety was shown by Mr. M. MOUNTFORD, and in recognition of its great merit and in consideration of its never having received an Award, it was granted a First-class Certificate.

AWARDS OF MERIT.

Tomatos.

Princess of Wales.—SUTTON & SONS.

Holmes' Supreme.—BARR & SONS, HURST & SONS.

Norfolk Hero.—G. W. MILLER, Wisbech.

Fillbasket.—LANTON BROS.

New Dwarf Red.—JAS. VEITCH & SONS.

Satisfaction.—SUTTON & SONS.

Yellow ChERRY.—JAS. VEITCH & SONS. Small but specially commended for flavour.

Potatos.

Rouge Royal.—DOBBIE & CO. A "coloured" kidney variety.

British Queen.—J. F. WILLIAMSON, Mallow.

Epiquire.—SUTTON & SONS.

Harbinger.—SUTTON & SONS, and BARR & SONS.

Ideal.—LANTON BROS., and G. CARTER, Cottenham.

May Queen.—SUTTON & SONS, and HURST & SONS.

Peas

The BCU, The Scotsman. Both of these are of medium height, the haulm attaining about 4 feet in length. Both had heavy crops of pods, which were long, tapering, and well filled with Peas. Both from Messrs. BELL & BIEBERSTEDT, Leith.

NEWBURY HORTICULTURAL.

AUGUST 7.—The fifty-seventh annual show of the above Society was held in the beautiful grounds of Goldwell Park on the above date, and from a horticultural point of view was a great success, though unfortunately the weather was stormy. The show is managed by a good working Committee, and the Mayor for the year is President, ably supported by the Corporation, the result being that Newbury show is a red-letter day, and largely patronised. There were nearly a thousand entries this year, the weakest classes being those for large specimen plants; and hardy fruit was less abundant than usual; but cut flowers and other exhibits well made up the deficiency.

Open Classes.—These are always a feature at this show, and usually the same exhibitors each year have a stiff fight for the honours. Mr. C. ROSS, of Welford Park, the well-known raiser of hardy fruit, was 1st with fine specimens for six stove and greenhouse foliage plants, having medium-sized but beautifully-coloured plants. Mr. J. HOWARD, gr. to Lady SUTTON, was a close 2nd.

For six plants in flower, Mr. T. SURMAN, gr. to H. M. BEST, Esq., Donnington Grove, was 1st with well-flowered plants, having good *Clerodendrons* and *Allamanda*.

In the class for ten exotic Ferns, Mr. HOWARD was an easy 1st; Mr. LOCK, Tile Barn Garden, 2nd.

Messrs. SURMAN & JOHNSON had the best *Coleus*, and Mr. SURMAN had grand specimen *Fuchsias*; Mr. JOHNSON the best specimen plant in bloom, and Mr. C. ROSS the best foliage plant.

The class for the best model conservatory arrangement was keenly contested, Mr. C. ROSS was 1st with splendid material admirably arranged; Mr. J. HOWARD being a close 2nd, and Mr. CLARK 3rd with smaller plants but of good quality.

Roses.—These flowers were scarcely up to the usual standard at these shows, owing no doubt to the recent hot weather and storms. Messrs. COOLING & SON, Bath, had twenty-four very good blooms in the class for that number, and were an easy 1st. Lady SUTTON was placed 2nd with smaller blooms. For smaller collections, Messrs. MEAD, COX, and SMITH were the leading exhibitors in the order named.

Cut Flowers.—The class for twenty-four bunches of cut blooms was well contested, the 1st prize lot being excellent. These came from Mr. C. SURMAN, gr. to W. G. FELLOWS, Esq. Mr. H. SMITH was 2nd; and Mr. P. RANDALL, 3rd. Of Carnations, Messrs. FILEWOOD, COX, and TRANTOR had the best blooms. Mr. J. R. TRANTOR, Henley, had splendid *Dahlias*. Miss B. FROST was 1st for a bridal bouquet with splendidly arranged flowers.

Table Decorations.—The classes for these were well contested, but drapery and coloured material were used too freely. Mrs. C. STRADLING was 1st with an arrangement composed of pink and mauve Sweet Peas.

Fruit.—For a collection of six dishes, to include a Pineapple, Mr. J. HOWARD secured the 1st place, having excellent Grapes and Peaches. The same exhibitor was 1st in the class for the best Pineapple. The best Black Hamburg Grapes came from Mr. T. SURMAN. For any other black variety, Messrs. LOCK and SURMAN were the successful exhibitors. Of Muscats, Mr. J. HOWARD had good bunches; and Mr. J. LRES the best example of any other white Grapes. Mr. ROSS easily led in the class for dessert Apples; while Mr. HOWARD staged the best culinary Apples.

Vegetables were a great feature, and occupied much space; the cottagers' exhibits alone formed a show in themselves. For twelve distinct kinds of vegetables, Mr. H. KEEP, Aldermaston, was an easy first; closely followed by Messrs. SURMAN and HOWARD, who took 2nd and 3rd places respectively. The cottagers' exhibits were excellent, being clean and of better quality than is often seen.

RAMSEY HORTICULTURAL.

ANNUAL SHOW.

AUGUST 7.—The thirteenth annual show in connection with the Ramsey Horticultural Society took place in the Abbey Park, by kind permission of Lord de Ramsey, on the above date, and was fairly well attended. There was a record number of entries, and the quality of the exhibits has never been excelled. As usual, the Roses and Sweet Peas made a grand show, and attracted considerable attention. Some excellent Carnations were also displayed. The table decoration class attracted more competitors than usual, and the work was exceedingly good. The vegetable and fruit sections were well patronised, and the show of Apples in particular was worthy of note. Messrs. J. E. PERKINS, Huntingdon, and BRADLEY and BROWN showed collections not for competition.

ROYAL HORTICULTURAL OF IRELAND.

AUGUST 9.—The autumn flower show of the Royal Horticultural Society of Ireland took place on the above date at St. Helen's, Booterstown, the beautiful residence of Sir John Nutting, Bt., D.L. While the numbers of entries and the quality of the exhibits showed a considerable advance over those of previous years, the weather unfortunately precluded a very large attendance.

The fruit, especially the Grapes, was very fine, there being more entries, and the quality of the specimens better than for some years past. The show of Roses was excellent, while the Sweet Pea section, and especially the exhibit of Mr. HENRY J. R. DIGGES was said to be the finest which experienced judges had ever seen.

The *Begonias* were also a remarkably fine collection, and Lord CLONBROCK carried off the most coveted prize in this class.

The exhibits by the members of the trade were marked features in the show; Messrs. DREMMOND & SON showed a very fine stand of cut flowers; Messrs. HOGG & ROBERTSON received a Gold Medal for *Gladioli*, *Montbretias*, Sweet Peas, &c.; whilst DICKSONS, Chester, had similar exhibitions, and Messrs. ECKFORD showed a fine stand of Sweet Peas.

The display of *Begonias*, *Gladioli*, &c., by Messrs. HARTLAND, of Cork, attracted much attention.

Messrs. RENNICK & Co. had a nice stand of shrubs, and Messrs. WATSON & SON showed some beautiful Carnations and Roses. There was also a fine exhibit of plants and flowers by Messrs. RAMSAY, Ballsbridge.

Another feature in the exhibition was the fruit grown in pots shown by Mr. S. ANKETELL JONES, J.P., Gowran, Co. Kilkenny.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

AUGUST 14.—The monthly Committee meeting of this Society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on the evening of the above date, Mr. Chas. H. Curtis in the chair. Five new members were elected. The amount paid for sickness during the past five weeks was £30 3s., nine members being on the Sick Fund at the present time, five of whom are now on half-pay.

GARDENERS' DEBATING SOCIETIES.

READING AND DISTRICT GARDENERS.—During the past month two very pleasant meetings of the above Association have been held. The first was an evening gathering, when about 100 members, by the kind permission of Mr. and Mrs. Friedlander, paid a visit to the gardens and grounds of Whiteknights Park, Mr. Bright, the head gardener, has been a warm supporter of the Association from its commencement. The houses were first inspected. Peaches and Nectarine-trees grown in small boxes were carrying splendid crops of fruit of large size and of good colour. The kitchen-garden contained good crops of vegetables. A feature of the terrace-gardens was four boxes containing Sweet Williams. The Secretary conveyed to Mr. and Mrs. Friedlander, who met the party in the grounds, the thanks of the members present for their kindness in throwing open the gardens for inspection. The second event was the annual outing, which proved to be one of the most successful of the many held by the Association. The party, 116 in all, proceeded to Blenheim, his Grace the Duke of Marlborough having kindly given permission for the Palace gardens to be thrown open for the members' inspection. The party, under the guidance of Mr. Garrett, the head gardener, proceeded to the Palace, where special facilities had been granted for the members to look through the state apartments. The gardens and ornamental grounds were next visited, the Italian garden attracting much attention. The walk by the lake through the "American garden" and through the shady glades leading to the kitchen-garden and glass-houses was greatly enjoyed. The crops of vegetables and fruit were in excellent condition, whilst the Carnations were the feature of the flowers under glass. The party arrived home at 8 o'clock, one and all having spent a most enjoyable day, thanks to the hospitality of the President, and to the arrangements made by Mr. Garrett.

EGHAM AND DISTRICT GARDENERS.—At the last monthly meeting of this Society, Mr. W. Swan in the chair, Mr. G. Lingwood gave a short paper on the "Tuberous Begonia," explaining in detail the best methods of raising this lovely plant from seed and from tubers. He also gave some useful information as to the best soil for growing them in beds, &c. At the same meeting Mr. Wheeler read two short papers on the "Calceolarias and Cyclamen." A hearty vote of thanks was accorded to the reader of these instructive papers. Among other exhibits at the meeting, the President, W. G. Regan, Esq. (gr., Mr. Lingwood), contributed a group of *Kex Begonias*, arranged with Maidenhair Fern. Mr. Worstoid also brought a group of foliage and flowering plants.

Obituary.

REV. W. KEITH.—The death of this gentleman causes another gap in the ranks of the older mycologists, whose work was done in the latter half of the 19th century, under the influence of the writings of Fries and Berkeley. With the last-named Dr. Keith had much active correspondence, whilst with the views of the former on the Hymenomycetes no one was more conversant. Living in the far North, where the flora corresponds to a large extent with that of Sweden, Dr. Keith threw himself with his characteristic energy into the study of the Pine-loving species, and especially of the *Cortinarii*. Of these no British mycologist that it has been my privilege to meet ever possessed so accurate and extensive a knowledge of their naked-eye characters and habit of growth. *Charles B. Plowright.*

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending August 12, is furnished from the Meteorological Office:—

"The weather during this period was of a rather unsettled type generally, but fairer in the south and east than elsewhere. Thunderstorms were experienced some time during the earlier half of the week in many places in the Midland Counties and N. and N.E. of England, and also at some Scotch stations, and on Wednesday or Thursday in the east and south of Ireland.

"The temperature was 1° or 2° below the mean over the kingdom generally, but just equal to it in England, E. The highest of the maxima were recorded on somewhat variable dates, and ranged from 78° in England, S., and 75° in the Midland Counties, to 69° in Scotland, E., England, N.W., and the Channel Islands, and to 67° in Scotland, W. The lowest of the minima occurred, as a general rule, on the 6th. In Scotland, E., England, N.E., and N.W., the thermometer fell to 38°, but elsewhere the minima varied from 41° in Scotland, W., and Ireland, N., to 44° in England, E. and S.W., and Ireland, S., and to 55° in the Channel Islands.

"The rainfall exceeded the mean in Scotland, N., and Ireland, N., but was less in the other districts.

"The bright sunshine differed little from the normal, being slightly above it in some districts, and a few hours below it in others. The percentage of the possible duration ranged from 49 in the Channel Islands, and 45 in England, S., to 29 in Ireland, S., 21 in Scotland, N., and to 23 in Ireland, N."

THE WEATHER IN WEST HERTS.

Very Dry and Sunny.—The first four days of the past week proved cool for the time of year, but on each of the last three days the temperature in the thermometer screen exceeded 71°. All the nights but one, however, have been unseasonably cold, and on the coldest night the exposed thermometer registered a reading within 8° of the freezing point. At 2 feet deep the ground is now of about average warmth, but at 1 foot deep it is about 1° warmer than is seasonable. Very light showers of rain fell on each of the first two days of the week, but since then the weather has been perfectly dry. It is now nearly five weeks since any measurable quantity of rain-water came through the bare soil percolation gauge, but a few drops still continue each day to trickle through it during the twenty-four hours. The sun shone on an average for seven hours a day, which is about an hour a day in excess of a seasonable duration. Calms and light airs prevailed throughout the week, and for the last two days the direction has been some easterly point of the compass. The mean amount of moisture in the air at 3 P.M. was about 6 per cent. in defect of a seasonable quantity for that hour in the middle of August. E. M., Berkhamsted, August 16, 1905.

[For actual temperature and condition of barometer at time of going to Press, see p. 150.]

MARKETS.

COVENT GARDEN, August 16.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

REMARKS.—Prices for Tomatos have an upward tendency, but this will not continue. Some good samples are to be seen from Jersey; in fact the Tomatos from this Island, are this year of excellent quality; still, there is not quite the demand for them as there is for English, as they lack flavour. A few of the Claret Bananas have arrived, but they did not travel well, arriving in a very unsaleable condition, and generally over-ripe. The average price for these fruits is from 5s. to 7s. per bunch. Some good fruit is arriving from California, chiefly Plums and Pears, the quality being excellent. The former are making from 6s. to 8s. per case, and the Pears from 5s. to 8s. per case, which prices are considered moderately cheap. Trade generally rather quiet.

COVENT GARDEN FLOWER MARKET.

TRADE continues very quiet; a few things are required for country orders, but most of the plants are sold to costers for barrow trade, and this means very low prices. It is scarcely safe to quote prices for the guidance of provincial buyers. A salesman informed me this morning that material ordered realised fair prices, but the residue had to be sold for any price that was bid for it. It is rather interesting to note the offers made by some of the costers. Sometimes they get things their own way, but it not infrequently happens that they disgust the salesmen, and are told to take their money where they may do better. Among flowering plants Verbenas are still conspicuous, also Zonal and show Pelargoniums. Marguerites are of very good quality. Bouvardias are seen from several growers. Chinese Asters in pots are good. There are now large quantities that have been taken from the ground with the first flowers expanded; these are sold at very low prices. Rhodanthe is good. Lilliums, especially the lancifolium rubrum, are overplentiful, and realise scarcely sufficient to pay for the cost of bulbs and pots. A few very good Fuchsias are still seen. Heliotrope in well-flowered plants is plentiful. Campanulas are of good quality. Some good Cannas are also seen; but the flowers of these do not remain in condition for any length of time. There are already seen Chrysanthemums in pots, but these are not of best quality. Zinnias and Coreopsis are still obtainable. Some Dahlias flowering in pots are seen;

also Tomatoes and Egg-plants in pots with ripe fruits, the latter with two or three good fruits on each. Among Ferns, Palms, and other foliage-plants there is little variation; the supplies are more than equal to all demands. Hardy climbers, Conifers and other hardy shrubs are plentiful and good.

CUT FLOWERS.

There is little to record in cut flowers just now, except that there must be much waste. Lilliums are very good, and still over-plentiful. Sweet Peas are also fairly good, but with short stems. The quality of Roses varies very much; there are some good blooms, but many are of very indifferent quality. Carnations also vary much, both in prices and in quality. Asters, both English-grown and imported ones, are very good. The immense quantities arriving from France spoil the trade for English produce. Gladiolus are over-plentiful, but very few really good spikes are seen, and the flowers are usually very small. Quantities of hardy flowers come into the market. The Statice, in white, yellow, and blue colours, have been very plentiful. *Gypsophila elegans* is still seen, but most buyers prefer *G. paniculata*; some of the double variety of this species is now seen. I find that most growers who bought this found it a good investment. Gardenias, Stephanotis, Tuberoses, and Eucharis are procurable at low prices. All kinds of cut foliage is plentiful. Oak sprays with red-bronze-tinted leaves are pretty. Up to last week we were getting the Galax leaves in good colour, but there will be no more for some time. Asparagus and Smilax in long trails are very good. All other seasonable foliage is over plentiful. *A. H., Wednesday, August 16.*

FRUITS AND VEGETABLES.

The following are the latest wholesale prices to hand from the undernoted markets:—

LIVERPOOL.—Wholesale: Potatoes, 2s. 6d. to 3s. 10d per cwt.; Kidneys, 3s. 6d. to 4s. 6d. do.; Turnips, 4d. to 8d. per dozen bundles; Swedes, 3s. to 3s. 6d. per cwt.; Carrots, 6d. to 8d. per dozen bunches; Onions, foreign, 1s. 6d. to 3s. per bag; Parsley, 4d. to 6d. per dozen bunches; Lettuces, 6d. to 10d. per dozen; Cucumbers, 1s. 9d. to 2s. 6d. per dozen; Cabbages, 6d. to 1s. 3d. do.; Peas, 5s. to 6s. per hamper; Beans, 2s. to 2s. 3d. do.; Kidneys, 1s. to 1s. 6d. per peck; Scarlet Runners, 1s. to 1s. 6d. do.—Retail: Potatoes, 10d. per peck; Green Peas, 6d. to 9d. do.; Cucumbers, 2d. each; Tomatoes, 1½d. to 6d. per lb.; Grapes, foreign, 6d. do.; Apples, 2d. do.; Pears, 3d. do.; Plums, 4d. do.; Mushrooms, 1s. do.

DUBLIN.—Cabbages, York, 10s. to 18s. 9d. per load; Carrots, 1s. to 1s. 2d. per dozen; Turnips, white, 6d. to 8d. per bunch; Rhubarb, 8d. to 10d. per 12 bundles; Salad, 3d. to 4d. per dozen; Onions, Tripoli, 4d. to 6d. per bundle; Mushrooms, 6d. to 3s. 6d. per float; Potatoes, 3s. to 3s. 2d. per cwt., top prices for best 3s. 6d. per cwt.

EDINBURGH.—Grapes, English, 1s. 6d. per lb.; do. Almeria, 1s. 6d. to 12s. 6d. per barrel; Lemons, Palermo, 15s. 6d. to 25s. per case; Apples, American, 18s. 6d. to 21s. per barrel; Barcelona Nuts, 36s. to 38s. 6d. per bag; Melons, 11s. to 15s. per case; Bananas, 5s. 6d. to 10s. per bunch; Figs, 9s. per dozen; Pears, French, 2s. 6d. to 7s. 6d. per box; Green Gages, 5s. 6d. to 6s. 6d. per half-bushel; Plums, French, 4s. to 6s. 6d. per bushel; Walnuts, Italian, 6s. 3d. per stone; Tomatoes, Guernsey, 4d. to 5d. per lb.; Onions, Valencia, 5s. 6d. to 6s. 6d. per box; Carrots, 3s. 6d. per bag.

REPORTS ON COLONIAL BOTANIC GARDENS AND FARMS.—We have received the *Annual Reports on the Botanic Station, Tobago, 1904-5*. The Gardens are in good condition, the nurseries maintained and extended, and many new plants are available. The Botanic Station reports are satisfactory, in spite of the extreme dryness of the season. Sir Daniel Morris, who paid official visits to the Station, comments most favourably upon its condition.—*Reports on the Botanic Station, Agricultural School and Land Settlement Scheme, St. Vincent, 1904-5*. The condition of the Garden is satisfactory; useful work has been done in re-arranging the collections of varieties of Bananas and Pineapples. "The proud position obtained by St. Vincent Cotton-growers of producing the highest-priced Cotton in the Empire should be a matter for congratulation to all concerned."—*Report on the Botanic Gardens of British Guiana and their Work, 1904-5*.—The Gardens were kept in good condition in spite of drought from August to December. The Herbarium has been got into good order. The complete Flora of British Guiana has yet been published, as owing to the large area and difficulty of access to certain parts of it it is doubtful if more than three-fourths or even two-thirds of the indigenous species have yet been collected.—*Reports on Experimental Farms, Ottawa*. The general results of farmwork throughout the Dominion have been fairly satisfactory. Drought and the severe winter caused much damage. Increasing interest is taken by farmers in the work and reports of the farms. Tests were made in connection with cross-bred Apples, the vitality of seed-grain, and with fertilisers. The horticulturist reports favourably on the result of Apples imported to England and Ireland, and on the growth of Potatoes during the year. The botanist mentions good work done in the herbarium and experiments in reclaiming sand-hills.—*Central Experimental Farm, Ottawa, Canada, Bulletin, No. 49, The Potato and its Culture*, with lists of varieties found most useful, by W. T. Macoun; Bulletin No. 50, *The Milling and Chemical Value of the Grades of Wheat in the Manitoba Inspection Division Crop of 1904, Part I*, by Chas. E. Saunders, Ph.D.; Part II, by Frank T. Shultz.

GARDENING APPOINTMENTS.

MR. F. CLARKE, many years in the Gardens at Henham Hall, Wangford, Suffolk, as Head Gardener to CALVER MASON, Esq., Broadwater House, Ipswich. He entered upon the appointment at the end of July.

MR. CHAS. TERRY, for the last eight years Head Gardener to E. T. HORLEY, Esq., has been appointed to manage the St. Neots Nursery for Messrs. PERKINS & SONS, Northampton and Ilfording.

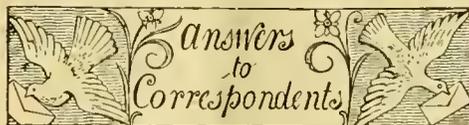

MR. W. ABRAHAMS, for the last five years as General Foreman at Papworth Hall Gardens, has been appointed to succeed Mr. TERRY in that capacity.

MR. H. J. SKITT has been appointed Head Gardener to Sir CHARLES WELBY, Bart. C.B., M.P., Denton Manor, Grantham, in succession to Mr. J. MALBY (who has relinquished the post of Gardener, and will in future act as Steward). Mr. SKITT's services date from September 1.

MR. GEORGE SMITH, for the past two years as Foreman and Head Gardener at Westhope Manor, Craven Arms, Salop, as Gardener to F. COOKSON, Esq., The Old Palace, Chippenham, Wiltshire.

ENQUIRY.

A READER of the *Gardeners' Chronicle* would be glad of information concerning the Strawberry called the Giant Middlesex variety. *F. D.*

BELLADONNA LILIES: *C. E. L.* It is quite natural for the bulbs to take a rest. They will probably flower again next year, or it may be not till the year after. The foliage is probably also dying off naturally. Very little moisture will be required till the leaves begin to grow in spring.

BOOKS: *C. P. & Co.* We know of no such book, but we believe one is in preparation.

BOOKS ON MANURES: *R. B. Manures and the Principles of Manuring*, by C. M. Aikman. Price 6s. 10d.; and *Manures for Special Garden Crops*, by A. B. Griffiths. Price 2s. 3d. Both are obtainable (post-free) from our Publishing Department.

CAMPBELL'S SULPHUR VAPORISER: *J. E.* This was highly spoken of by one of our correspondents, who narrated his experience lately in the *Gardeners' Chronicle*.

CARNATION: *J. McL.* The flowers are affected with a smut fungus. Destroy the plant at once. The *Dianthus Heddewigii* is also affected with some fungus; see our issue for next week.

CARNATIONS: *R. K.* Nothing particular.

CHRYSANTHEMUMS: *G. W. P.* The proper manner of "taking the bud," as it is termed by growers, differs so much that each variety needs special treatment in this respect. The trade growers in their catalogues indicate the best time and manner of stopping and timing Chrysanthemums, and you will do well to write for one of their lists. An article on the subject will be found in the *Calendar of Garden Operations*, 7½d. post-free, from our Publishing Department.

CLIMBING ROSES SUITABLE FOR A GREENHOUSE: *B. V.* The Tea-scented Roses and their hybrids embrace many beautiful varieties adaptable for training to a greenhouse roof. Even though you desire only white or rose-coloured varieties you will find an ample selection at your disposal, including (white) *White Maréchal Niel*, *Valentine Altermann*, *Madame Jules Gravereaux*, *Madame Jules Siegfried*, *Climbing Niphetos*; (reds or crimson) *Ards Pillar*, *Francis Crousse*, *Madame Berard*, *Madame Marie Lavallé*, *Reine Marie Henriette*, *Reine Olga*.

FALMOUTH: *M. B.* A complete list of plants grown in Devonshire and Cornwall would be much too lengthy for us to give. You will find numerous references in our back numbers.

FRUIT-DRYING: *J. P.* For your purpose the best plan would be to dry them in a baker's oven on a tray, removing them at times to see how the drying is proceeding. Far better is the process of bottling fruits, which can be performed by placing the bottles containing the fruits in a deep fish-kettle of water, and when the water

is brought to the boiling-point, securely corking the bottles. Outfits, with bottles, &c., for the purpose, can be had for a reasonable cost. Another good plan is to bake the Plums, &c., in a stone jar, cover over, and then bury the jar in the garden until required.

GRAPES: *W. J. S.* The variety is Golden Ham-burgh, which somewhat resembles Buckland Sweetwater, but is of better flavour.

GYMNOSPORANGIUM: *B. V.* There is no known remedy short of destroying the Juniper or the Pear trees, or both. Burn as many of the affected shoots as you can.

HORTICULTURAL HALL: *J. C.* Too late for insertion this week; but why not make your complaint at headquarters?

LAWNS: *Felix.* Any manure containing nitrogen, such as well-rotted manure or nitrate of soda, will by encouraging the grasses kill the weeds. A drop of sulphuric acid dropped from a glass rod on to the heart of the weed will kill it, but be careful how you handle the acid as it is very corrosive. As to the Ivy, we think you will do well to consult some of the larger nurserymen, who will give you the information you require better than we could do.

NAMES OF PLANTS: *H. E., Suffolk.* *Trachelium coeruleum.*—*D. R.* We cannot undertake to name varieties of Roses. Send to a Rose-grower who has opportunities of comparison with his named plants.—*Pancreaticum.* *Asclepias curassavica* and *Pancreaticum macrostephanum.*—*A. Y. L.* 1, *Dendrobium Draconis*; 2, *Oncidium prætextum*—*W. D.* Omitted from last week. *Hemigraphis colorata.*—*F. E. A.* 1, *Zephyranthes candida*; 2, *Yucca filamentosa*; 3, *Cupressus nootkatensis* (*Thuopsis borealis* of gardens); 4, *Thuja plicata*, true, also known as *gigantea* and *Lobbi*; 5, *Leycesteria formosa*; 6, *Spiraea Douglasi.*—*T. R.* 1, *Sedum Telephium* var.; 2, *Abelia triflora*; 3, *Griselinia littoralis.*—*J. L.* *Carduus Marianus*, The Virgin's Thistle.—*C., Atrincham.* 1 and 2, both forms of *Kochia scoparia.* One is the seedling stage. We do not think there are two species. *W. M.* 1 and 2 next week; 3, *Hoya carnosia*; 4, *Ruscus racemosus.*—*W. E. B.* *Saponaria officinalis.*—*H. J. B.* *Rhus Cotinus*, the Wig plant.—*W. S.* 1, *Solidago virga aurea*; 2, *Hieracium subaudium*; 3, *Hieracium Spondylium*; 4, *Atriplex patula.*

PEONIES: *J. F.* We suspect the trouble is at the root. There is no separate work in English, but, of course, the subject is alluded to in most of the text-books.

PEARS DEFORMED: *R. W. R.* Pears such as you send have often been figured in our columns. They are swollen and distorted branches, with no true fruit or core in them. If you were a cute Yankee you would advertise them as coreless Pears!

POTATO LEAVES: *A. M.* The leaves bear no trace of fungus disease, but their appearance is compatible with that caused by extreme sun-heat following a period of drought.

POTATOS: *W. J. W.* The tubers have developed supertuberation, but what induces this abnormality we are at a loss to understand.

PUBLIC GARDENS: *B. R. E. R.* You must watch the advertising columns, or advertise yourself.

TOMATOS: *G. E.* The fruits are affected with a fungus, *Cladosporium lycopersicum.* You will find an illustration of this disease, with remedial measures, on pp. 45, 46, of the *Calendar of Garden Operations*, 7½d. post-free, from our Publishing Department.

VINE LEAVES: *G. T.* The leaves are studded with warts, which are caused by too stuffy an atmosphere and not sufficient ventilation. It is not unlikely there may be mites also, but we cannot find any.

THE GENUS AGAVE.

ONE of the chief advantages which a garden situated on the sheltered shore of the Mediterranean affords is the flowering of many plants which elsewhere must be kept under glass, where they rarely or perhaps never produce their flowers.

The flowering of an Agave is an event in any garden, but we have here every summer a number of these plants in bloom. Some species, as Agave Bouchei, A. micracantha, A. albicans, A. polyacantha, A. mitis, &c, flower every year, often producing several spikes. They all belong to the section "Littæa," and do not die off after they have flowered, but the main rosette divides into several others, which when large enough flower again and repeat this same process until in a few years a large bush is formed.

Agave Bouchei forms a short stem, whilst the others are really caespitose.

Agave striata striata is just showing its flower-spike, with its curious long, white scarioso, empty bracts. These empty bracts of the scape form an excellent specific character, to which I should like to draw the attention of botanists.

Agave polyacantha varies much in the shape of its leaves; young plants with a simple rosette have their leaves generally broader than those which the same plant produces after it begins to divide. Agave densiflora, Hooker (*Botanical Magazine*, t. 5,006), is synonymous with this. I contributed a short note and a photograph of this species to the *Monatsschrift für Kakteenkunde*.

Agave albicans is also about to flower again this year. Recently, when with Sir Thomas Hanbury and Professor Wm.

Trelease, I had occasion to visit the well-known gardens of Mr. L. Winter in Bordighera, I saw a great number of this species just about to flower. There were some with brown, and others with paler marginal prickles, and the former also had darker, almost brownish flowers, whilst the latter had paler greenish flowers. It is a very variable plant, and A. Celsii may possibly belong to it.

Another very interesting plant of the Littæa group was just in flower when its author, Professor Wm. Trelease, came to visit La Mortola. It is Agave Engelmanni. It is only a small plant, which was raised from seeds received years ago from the Missouri Botanic Gardens, St. Louis. It is a curious species, having the flowers in groups of four to six on very short branches. In this it agrees with A. multiflora, Todaro, to which it is closely allied; but still there is sufficient reason to keep the two species distinct. The leaves in Agave Engelmanni are broader and more spatulate; the perianth too differs essentially. I found our plant to agree well with the description and figures given by its distinguished author in the Third Annual Report of the Missouri Botanic Gardens (1892), 16 f., t. 55, 56.

Agave Henriquesii, Baker, is now in flower, and will ripen its seeds when these lines are in the press. It was described and figured by Mr. J. G. Baker in the *Gardeners' Chronicle*, 1887, i., p. 32, from material sent to him by Professor Henriques, Director of the Coimbra Botanic Gardens. We have repeatedly grown young plants from seeds received from Coimbra, but this is the first plant that has produced flower. Our plant is smaller than the one described by Mr. Baker. The leaves only reach a length of 50 cm., and are 10 cm. broad; they are thick, dark-green, and terminated by a spine 4 cm. in length. The scape, together with the inflorescence, is about 3 m. high. The flower is 5 cm. long, with a slender, subtrigonal ovary; the tube is short, and the outer segments of the perianth are linear-lanceolate, the inner narrower, linear; all about 22 mm. long. The stamens are somewhat unequal, those opposite the inner segments, the longest, measuring about 6 cm. from their base.

This year Agave Béguini, a hybrid raised by the Abbé Béguin at Brignoles, and presented by him to this garden, is also for the first time in flower. A description of it will be published later on.

MANFREDA.

Of the smaller Agaves, which are now separated from this genus by American botanists, but kept under the sub-genus Manfreda by Mr. Baker, there are or will shortly be in flower—Agave maculata, A. variegata and A. virginica. Whether a generic distinction in this case is justified or not I do not wish to decide, but in many other genera botanists would certainly not attempt it on the ground of such slight differences.

The Agaves of the sub-genera Manfreda and Littæa are but small plants if compared with most of those of the sub-genus Euagave. The last-named are in many cases gigantic and majestic plants, to which chiefly the name Agave, from the Greek ἄγανος = stately, was applied. Their enormous rosettes die off with the ripening of the seeds. Several specimens of the giant of the genus, Agave

Salmiana, of which there are a great number of varieties at La Mortola, are just about to flower. Their gigantic scape is terminated by a large panicle bearing many hundreds of pale yellow flowers. Our largest plants have leaves about 2.15 m. long. The plant is commonly cultivated in Mexico for making pulque, a drink much esteemed by the natives.

Very similar to it in flower, and nearly as big, is Agave ferox, which will also be shortly in bloom at La Mortola.

The following, also belonging to Euagave, will be in flower this summer: Agave Franzosini, A. americana, A. picta, A. mexicana, A. applanata, A. rigida, and A. sisalana.

Agave Franzosini, Baker, was first described in the *Gardeners' Chronicle*. It is a very distinct species, far exceeding the others in its elegance, and especially on account of its white or nearly greyish-blue leaves, which have a rough surface.

Agave americana is now found half wild all along the Mediterranean shores. There exist also variegated forms of it. A. picta, Salm., is generally considered to be such a variegated form. Even in Mr. Baker's *Handbook of Amaryllidaceous Plants* the same error occurs. But, as I pointed out some time ago in the *Gartenwelt*, A. picta is quite another species, and has nothing whatever to do with A. americana.

Agave picta, Salm., was originally introduced in its variegated form. This was figured in the *Botanical Magazine*, t. 3654, under the erroneous name of A. americana variegata. Prince Salm-Dyck, who only knew young variegated plants, recognised them at once as a different species, and gave its description with the above name in *Bonplandia*, vii. (1859), 88, where he writes that he had not seen the green type. Of course, nobody had seen it until these variegated plants flowered, and from their seeds were produced seedlings of the green type. Such was the case at La Mortola, where we have whole groups of such plants. When I first came across one of them it seemed to me as if I knew it already, and yet it looked so strange that I failed to recognise it at first. Agave americana has shorter and stiffer glaucous leaves, with a stout terminal spine, whilst Agave picta has the leaves longer, dark green, more bent, and often recurved, but always more elegant. The terminal spine, moreover, is longer and finer, similar to that of A. Salmiana. The panicle is also more elongated in Agave picta than in A. americana.

The flowering of so many Agaves may be due to the great heat of last summer. *Alwin Berger, La Mortola, June 21, 1905.*

[A large number of species was figured in our columns in the years 1871, 1872, 1877, 1882, and 1883. Ed.]

FAR EASTERN MAPLES.—Mr. JAMES H. VEITCH has reproduced in pamphlet form his paper from the *Journal of the Royal Horticultural Society* on Far Eastern Maples. The value of these plants is even now not sufficiently recognised, and those mentioned in the pages before us, and peculiar to China, Japan, and neighbouring countries, offer a wonderful variety of form, colour, and habit such as should suit the requirements or fancies of every grower. The illustrations accompanying the letterpress give some idea of the diversity of Maples in general form, and in shape and variegation of their leaves.

NEW OR NOTEWORTHY PLANTS.

SCHIZANDRA HENRYI, CLARKE.*

SCHIZANDRA is a small genus of little-known climbing shrubs which, combined with *Kadsura*, form a distinct tribe of Magnoliaceæ. This little

The species here illustrated (fig. 55) was introduced from Central China to the Veitchian nurseries by Mr. E. H. Wilson. It differs from other known species chiefly in the shape of its leaves and in the length and stoutness of its peduncles. The flowers are white, unisexual, and

this fleshy receptacle the mucilaginous berries are embedded. The whole fructification, Mr. Wilson tells us, is eaten by Chinese country-folk, who designate this plant the Tieh-ku-san.

This species is not uncommon on rocks in the mountains of Western Hupeh and Szechuan, at an altitude of between 2,000 and 5,000 feet. *S. grandiflora* also occurs in similar localities; whilst another species, *S. propinqua* var. *sinensis*, is very common in the Yang-tsze Valley up to 2,000 feet.

CRASSULA COLUMNARIS, L. fil.

This *Crassula* (fig. 56) belongs, with three other species, to the subgenus *Pyramidella*, of Harvey. One of these, *Crassula pyramidalis*, Linn. fil., is figured in *Botanical Magazine*, t. 7665. *C. multiiceps*, Haworth, was introduced to La Mortola in 1873 by Professor MacOwan, according to a pencil note found in the late Daniel Hanbury's

FIG. 55.—SCHIZANDRA HENRYI, Clarke: NEW HARDY SHRUB.

FIG. 56.—CRASSULA COLUMNARIS. (Enlarged.)

handwriting, but has been lost long ago, and is probably now not to be found in any garden. The fourth species, *C. semiorbicularis*, Ecklon and Zeyher, has, as far as I know, never been seen alive in Europe.

The *Pyramidella* *Crassulas* are among the oddest-looking Cape plants. This one, as Harvey says in *Flora Capensis*, ii., 358, exactly resembles one of the *Balanophoræ*. It has roundish, very obtuse leaves, closely packed in four rows along the short stems. The flowers are aggregated into a dense, capitate, and subglobose cyme. The calyx-lobes are free or nearly so, spatulate, and elegantly fringed with cartilaginous hairs. The petals are united at their base into an urceolate tube, and taper into long, linear (not lanceolate, as Harvey states), channelled points. The ovaries end in a short neck, with an oblique, somewhat capitate stigma. The little squamæ fixed behind each carpel at the bottom of the flower are—at least, in this and in *C. pyramidalis*—cordate-cuneate and stipitate, of a dull orange colour, in form similar but smaller than

tribe comprises about a dozen species, which, with the exception of *Schizandra coccinea*, a native of the Atlantic side of North America, are all confined to Eastern Asia.

* *Schizandra Henryi*, C. B. Clarke.—Scandens, foliis longe petiolatis ellipticis vel late ovatis utrinque acutatis; pedunculis petiolos superantibus. Henry in *Herb. Kew*, 1785, et 9193 b. Hupeh and Szechuan, Wilson!

borne in great profusion. The leaves are coriaceous, shining, with bright red petioles. In shape these leaves vary from elliptic, through broadly-ovate, to cordate-ovate-acuminate on one and the same individual. The twining stems are more or less triangular, each angle being prominently winged. After flowering the carpel-bearing column elongates very considerably and becomes fleshy; in

those of the little *Monanthes* of the Canaries and the Atlas mountains.

C. columnaris is from 1½ to 4 inches high; generally the stem is hardly visible, being hidden by the connate, thick, and roundish leaves, which are glaucous, finely punctate, and their sharp margins ciliated with short cartilaginous hairs. The upper surface is more or less concave, and plain green. It is a native of the western districts of Cape Colony, extending as far north as Little Namaqualand. La Mortola is indebted for this and many other interesting succulents to Dr. R. Marloth, of Cape Town, one of the most energetic and successful exploring botanists of South Africa.

In cultivation the *Crassulas* ought never to be allowed to become too dry, or they will wither and die away. But professional gardeners very often fail to cultivate plants which amateurs grow successfully; gardeners either believe that all succulents are plants of desert regions and can do without any care, or they fall into the other extreme and kill them by too much watering, especially in winter. *Alwin Berger, La Mortola, Ventimiglia, Italy.* [For an article on this plant see *Gardeners' Chronicle*, January 29, 1898, p. 66.]

NURSERY NOTES.

MESSRS. B. S. WILLIAMS & SON.

FOR many years the business founded by the late B. S. Williams, the father of the present proprietor, was successfully carried on at the Victoria and Paradise Nurseries, at Upper Holloway. Of late the builder has gradually encroached and hemmed in the areas under cultivation, shutting out light and air, and generally rendering the cultivation of all but the hardiest species of plants an impossible task.

In view of this state of things, the firm saw the necessity of removing their out-of-doors stock to Church End, Finchley, to a spot consisting of about twenty acres, at a distance of three-quarters of a mile from the railway station, and situated on the Hendon Road, where, amidst pastureland on every side, a nursery has been laid out on sloping ground facing south, the transfer having taken place six years ago. At about half a mile south is the site of the projected "Garden City." Here all kinds of plants can be made to succeed free from many of the evils connected with a town nursery. The land having been under grass for one hundred years or longer, affords ample plant food in the form of the decaying turf that will meet the needs of tree and shrub without manurial dressings for many years. The soil is an ideal one for the growth of fruit and forest trees, for herbaceous perennials, Conifers, Evergreens, and most sections of the Rose family.

At present but few glasshouses have been erected, but others will be built as occasions arise. The contents of the glasshouses observed on the occasion of a visit made lately, consisted of a fine lot of *Maréchal Niel*, *Corallina*, a climbing *China Rose*, and others cultivated in pots. One span-roofed house contained *Vitis purpurea*, for which there is a constant demand; *V. heterophylla variegata*, *Rubus laciniatus*, the fine deep pink-flowered *Pelargonium* (Ivy-leaf) *Mrs. Turner*. On one of the stages was a number of *Souvenir de la Malmaison* and fine border *Carnations* in pots, prepared for layering in pans; also a quantity of *Nicotiana Sanderiana* in pots. Another house contained plants of large size of *Hydrangea paniculata* having flower-heads of a very pure white colour in prodigious numbers. There were a few other houses full of plants, but at this season these contained nothing of much interest.

The main walk from the nursery entrance is bordered with choice Conifers and shrubs, mostly

evergreen, and showy hardy herbaceous perennial plants, all of which seem quite at home in the heavy loamy soil. Roses are found in quantity, distributed in "breaks" in various parts, and most varieties make strong growth, including most but not all of the Teas and Hybrid Teas. Some of these need winter protection, the valley in which the nursery lies being subject to late spring and early autumn frosts, and a low average temperature during the winter season. Very strong plants of *Crimson Rambler*, one year old from the bud, were of an average height of 10 feet. Excellent were the stands of *Mrs. John Laing*, *Jennie Dickson*, *Madame Gabrielle Luizette*, *Robert Duncan*, a very early bloomer, deep rose-pink in colour, and a full bloom; the climbing *W. J. Grant*, *Caroline Testout*, and *Cheshunt Hybrid*, the latter showing still plenty of blooms—good as a pillar or climbing variety. I noticed many "breaks" of bush Roses, but the exigencies of space forbid the mention of names.

Good breadths are planted with *Manetti Rose-stocks*, now ready for being budded.

That pretty *Rose Gruss an Teplitz* was observed in some quantity, and beautifully in flower.

The collection of *Phlox decussata* varieties was particularly noticeable for the number of striking colours it contained, as also that of *Pentstemons*, among the latter being *P. Newbury Gem* with flowers greatly resembling those of *P. Torreyi*, but possessing greater size; *P. James Day*, an extra fine flower; and *Niel McKinnon*. *Pyrethrum*, *Rudbeckias*, *Chrysanthemum lutescens* in variety, and *Kniphofias* (some eight varieties), *Dahlias* and shrubby *Chrysanthemums*, all capital plants; many sturdy plants of *Weigela* in variety, the beautiful *Berberis Thunbergi*, a profuse autumn flowerer, were observed in some quantity. *Golden-leaved Privet* (*Ligustrum ovalifolium aureum*) is a shrub for which there is a great demand locally, and of which large breaks were noted, trained both as bushes and standards.

FRUIT TREES.

Apples as bushes on the *Paradise* stock formed a noteworthy feature, the growth being clean, healthy and free from American blight, many of them fruiting heavily already. Large breadths of standard and pyramid-trained trees on the *Crab-stock* were excellent for orchard or garden planting, being free in growth, clean, and numbering eighty-seven varieties. Maiden trees receiving their first training were worthy of notice for their freedom of growth without too much exuberance.

Pear trees on wilding stocks for immediate planting, trained, standards and maidens, form a good lot, equalling in all points the preceding, as do those on the *Quince-stock*.

Peach and Nectarine trees grow in this fresh soil if anything too vigorously, but this will be corrected as time progresses and the soil gets somewhat poorer.

No *Apricots* were observed. *Plums* do grandly, developing clean, vigorous shoots, and consist chiefly of dwarf-trained examples in about a score of varieties.

MISCELLANEOUS PLANTS.

Prunus Lauro-Cerasus caucasica, *P. c. rotundifolia* and *P. c. latifolia* make a good show of stocky, compact planting material; also *Ribes* in variety, with vigorous growth. *Clematis* receive much attention, as do *Ivies*, of which many varieties are grown.

Among the varied Conifers observed were several choice species, as *Cupressus Lawsoniana Allumi*, with the habit of the type form, and leaves of a bluish tint; *Abies grandis*, *A. laiocarpa*, *A. nobilis*, *A. Nordmanniana*, and *A. concolor*. These were small specimens, of compact growth. Many *Poplars*, *Prunus Pissardi*, *Philadelphus*, *Oriental Plane*, *Euonymus*, *Deutzias* in variety, *Corylus Avellana purpurea* (purple

Hazel), *Cotoneaster frigida*, and *C. Simonsi* were noted, all of which are at home and good of their kind. A beautiful *Rhus*, apparently a variety of *glabra*, with pretty, finely-cut foliage, and with the young growth of shoots of a purplish tint, was noted. The *Lime* grows well in the stiff soil, and an excellent break of tall standard trees was a conspicuous feature.

It will be observed from the foregoing that excellent progress has been made by the firm, and that ordinary requirements can be efficiently met in most kinds of trees and shrubs, herbaceous perennials, &c. *F. M.*

MELONS.

THE present season appears to have been very favourable to the growth and production of good crops of highly-flavoured Melons; in fact we have rarely, if ever, had better results than we have had this season, the plants from the first growing strong and robust. The flowers were freely produced, and set well; the fruits swelled and finished splendidly. It has been my practice for some years past to grow four crops of these fruits annually—two successional crops in a house regulated in such a manner as to maintain the supply for as long a period as possible. My first crop is raised from seed sown in small pots at the end of January, the seedlings being planted-out about four weeks later on well-prepared beds composed of a suitable mixture of moderately heavy soil, which is made firm previous to and also after planting. For my last crop I usually sow the seed from the middle to the end of June—the young plants raised from this sowing (should the crop which they are intended to follow be not quite ripe, or still occupying the house) being shifted into larger-sized pots, and kept growing steadily until the house and borders intended for their reception are quite ready. By this time the plants will have attained a moderate size, and will quickly furnish the trellises on which they are trained. The crop of fruits produced from these plants usually ripens about the beginning of October, which in our case is considered late enough in the season.

My general practice differs very little from that of many successful Melon-growers, with probably this exception, that I favour cropping lightly—say from three to four fruits on each plant.

In training and growing Melons in houses gardeners who adopt the single stem system (a method I always follow) should never allow the plants to become overcrowded with useless shoots, and then severely prune and thin them at one time. Constant and frequent attention to this matter is most essential if good results are to be expected. Laterals should be thinned, leaving only enough to cover the trellises and produce the fruits as required.

When Melons are grown in small shallow borders and in a small quantity of soil, every attention must be paid to the watering, feeding, &c., dryness at the roots being most injurious to the plants' welfare. A top-dressing of rich, sweet loam should be given every ten days, and until the fruits have set and have reached a moderate size incorporate a sprinkling of some reliable artificial manure in each top dressing. It is marvellous what effect these repeated top-dressings have in keeping the roots and plants healthy and robust. When the fruits have reached about half their required size, I apply a mulching of well-decomposed manure, and this, with a few applications of weak manure liquid at intervals, are sufficient for their requirements. Some of the thin-skinned varieties have a tendency to split, but with care and attention to the root requirements and to the atmospheric conditions of the house, there need be no trouble in this respect. *H. Markham, Wrotham Park, Barnet.*

FRUIT REGISTER.

PEREGRINE PEACH.

We have rarely tasted a richer-flavoured Peach than this variety. It is one of Messrs. Rivers' introductions, and received a First-class Certificate in May last at the Royal Horticultural Society by a unanimous vote. It is a globular fruit, 3 inches in diameter, deeply lobed at both extremities, and of a very deep crimson colour. It belongs to the section with round glands to the leaf and with large flowers. Its descent is traced from Spenser (Nectarine), Albert Victor, and Prince of Wales.

Peregrine is stated by Messrs. Rivers to be a very reliable Peach, cropping well under all conditions; and the branches keep their foliage well, as was seen in the shapely specimens exhibited by Messrs. Rivers at one of the late meetings of the Royal Horticultural Society.

VARIEGATED CONIFERÆ.

In looking at an ordinary English garden in winter, we find that, with the exception of variegated Yew, Hollies, and Euonymus, the greater part of the colour is furnished by various Conifers, ranging from the glaucous blue of *Picea pungens* var. *glauca* to the brilliant gold of *Cupressus Lawsoniana* var. *lutea*. Variegation is sometimes a sign of weakness in a plant, and this is the case with some of the variegated Conifers; but the majority of them are quite as hardy and nearly as vigorous as the species to which they belong, though a few are rather fastidious as to soil and situation, which has sometimes led to their being condemned without sufficient reason. It is proposed in the following notes to mention either those which are easy to grow or which are of such merit as to warrant a little more care and attention being bestowed upon them.

CUPRESSUS.

C. macrocarpa var. *lutea*.—This is a plant of comparatively recent introduction, is fast-growing, and of a uniform bright yellow colour. It should have a sheltered, sunny situation, and a poor, rather dry soil. The shrub is fairly hardy, but requires shelter from high winds, as it grows almost too fast, and is liable to be damaged by gales. A good plan is to drive a spade in all round it annually for the first two or three years after planting, as this tends to check it somewhat, and also assists in the thickening of the stem.

Of *C. Lawsoniana* there are many coloured forms, but a good selection comprises *C. L.* var. *albo-spica*, a dense-growing, upright plant, with the ends of the shoots tipped with silvery-white; *C. L.* var. *lutea*, entirely bright golden-yellow in colour, and probably the best-coloured Conifer in cultivation; and *C. L.* var. *Westermanni*, which is variegated with yellow in addition to the bright golden colour of the younger wood. These three can be grown almost anywhere, but they are difficult subjects to transplant.

C. nootkatensis (*Thuyopsis borealis*) gives us vars. *albo-variegata* and *aureo-variegata*, with white and yellow variegation respectively. The former is of rapid growth, and should be planted on poor soil or it will tend to become green; while the latter should have good soil and every encouragement, as its rate of growth is rather slow. Both of these require watching in a small state to keep them to a single leader.

C. obtusa var. *filifera aurea*.—This is a bright, golden-coloured form of *C. o.* var. *filifera*, and is a singularly handsome plant with its long, thread-like branches. In a dwarf state it makes a suitable plant for the rockery, as it can be made to form a spreading bush by cutting out the leaders when they appear, but its best effect is seen when

grafted as a standard, the long, thread-like, golden shoots forming an umbrella-like top, and hanging down on either side.

C. o. var. *fil. variegata*.—This is mottled with creamy-white variegation, and makes a showy plant when it has attained a fair size.

C. o. var. *nana aurea*.—Probably no variegated Conifer is slower of growth than this, and certainly none is more showy when it has attained a fair size. On good ground and under favourable circumstances, it will reach a height of 6 feet in ten or twelve years, but its great beauty amply compensates for its slowness of growth. The branches are short and bluntly fan-shaped, each one perfect and in its place, and of a uniform intense golden-yellow colour, which attains its brightest tint during the winter months.

C. o. var. *tetragona aurea* resembles the above in its colour and rate of growth, but the branches are longer, and the foliage set much closer together. It is a handsome plant, and is rather more open in growth than the preceding.

C. pisifera var. *aurea* is a strong-growing plant tinted, though not very strongly, with yellow. It makes a large plant very quickly, and possesses the advantages of a fairly good colour and the ability to grow where some of the variegated Coniferæ will hardly live.

C. p. var. *plumosa argentea* is a slow-growing plant, very broad in proportion to its height, with feathery foliage tipped with creamy-white. It makes a good plant for tubs, or as a small specimen on terraces, &c.

C. p. var. *plumosa aurea* differs from the preceding in its stronger and more upright habit, and in its bright yellow colouring, which extends all over the branches, but which is usually most prominent on the sunny side. It was planted very extensively some years ago, but has lost favour entirely now, though it is worth planting where soil and situation are suitable for it.

C. p. var. *nana aureo-variegata*.—This is a dwarf, spreading plant about a foot or 18 inches by 3 feet or more in diameter, with dense-growing foliage marked with bright yellow. It is a good plant for the rockery, and will succeed in a comparatively dry place.

The above forms of *C. obtusa* and *C. pisifera* are more commonly met with under the term of *Retinospora*, and except where stated otherwise they require a cool, moist soil to grow in, as they usually become very thin and ragged on dry ground, even if it is fairly good. *J. C., Bagshot.*

(To be continued.)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and General Summary, ante, pp. 81-87.)

(Continued from p. 155.)

5, SOUTHERN COUNTIES.

KENT.—Fruit trees have made but little wood of late years, with the exception of those recently planted. We are well protected on the north and east, and this saved us from injury by the late frosts and cold winds. The abundant rains of last month [June] have helped us greatly. Our soil is a light loam overlying chalk. *E. Gilmore, Northbourne Abbey Gardens, Eastry.*

— There were good prospects for all kinds of fruits early in the season, but the late frosts and cold east winds almost ruined them; still, I have a moderate crop of most fruits. The soil is a good, deep brick-earth, which resists dry weather well. The garden is about 200 yards distant from the sea, with a south-easterly aspect. *F. Sparks, Walmer Place, Walmer.*

— The soil here is a sandy loam resting on gravel. Fruits of all kinds succeed with us.

Peaches and Nectarines do well on east walls. Apples, Pears, Plums, and Apricots are very few in quantity, but are of fairly good quality. Damsons are a very heavy crop. Cherries have been very good indeed, while Raspberries are exceptionally fine. *H. J. Knight, Preston Hall Gardens, Aylesford.*

— The heavy crop of Apples last year had undoubtedly much to do with the scarcity of blossom, and consequently little fruit this season. Pears generally flowered freely, but late frosts appeared, and ruined the crop. *Geo. Fennell, Bowden, Hadlow Road, Tonbridge.*

— Nearly all fruits are a failure with regard to quantity, but those that have developed are of exceptional quality, owing no doubt to the thinness of the crop. Cherries promised well, but they were ruined by the weather. Crops of all hard fruits are bad, with the exception of Damsons. *B. Champion, Mereworth.*

— Strawberries and Raspberries are the chief fruits grown in this district, and it was foreseen that the crops of Strawberries would be small in quantity after the destructive drought of last year, when they failed to build up their crowns. There was a scarcity of foliage all this spring. Trusses came weakly, and when the plants were in flower 9° of frost were experienced. Later, when the fruit began to colour, three days continuous rain caused the fruit to rot on the ground. Thus it is not surprising to find that Strawberries were a very short crop and of inferior quality. The varieties Royal Sovereign, Sir Joseph Paxton, and Veitch, are still grown for our main crops. Among newer varieties The Laxton and Trafalgar have been planted largely in fields, but they are not well spoken of. In gardens, Givon's Late Prolific is a great success. Raspberries are a splendid crop in fields. The soil varies from very hot gravel to good loam. *W. E. Humphreys, Blendon Hall Gardens, Bealey.*

— Our soil here is a heavy loam, with a subsoil of brick-earth. Pears as a rule succeed well with us, and last season the trees broke down with the weight of fruit they were carrying, but the only variety with an average crop this year is Clapp's Favourite. Small fruits were well with us; Strawberries fairly well. The Loganberry and American Blackberries do splendidly with us; we train them on trellises against the wall. The plants of Loganberries are carrying very heavy crops of splendid fruits. They should be more largely grown, as they are most useful for dessert and for cooking purposes. *W. Dixon, The Old House Gardens, Walmer.*

— Our gardens are situated on the southern slope of the lower greensand hills, the soil being a strong loam with many stones present. The height above sea-level rises from about 340 to 400 feet. Damson trees growing on the highest part of the gardens have scarcely any fruit; those about 30 feet lower down have rather less than an average crop. A neighbour whose orchard is situated directly below ours, at from 250 to 300 feet above sea-level, has quite an average crop. This is due to the interesting fact (as noted in my diary) that his Damson trees were on April 5 "almost white with bloom, while ours scarcely developed a single flower." The next four days, April 6 to 9, were the coldest experienced here since March 4, yet the trees with expanded blossoms appear to have suffered less than those with unexpanded flowers. I take daily thermometer observations by instruments which have been corrected at Kew Observatory. Apples are meagre in quantity everywhere in this district. The quality is indifferent, although the lowest temperature (shade) from April 20 to May 22 was 36°. Gooseberries are a heavy crop. *Alfred O. Walker, Ulcombe Place, near Maidstone.*

MIDDLESEX.—The fruit crops this year are the worst we have had for many years past. Two years ago there was a great failure among fruit, but it was not so general as this season. Many of our Apple trees are quite barren, few late kinds, such as Wellington and Lane's Prince Albert, and a very few early varieties are bearing crops. Plums on walls and elsewhere are a total failure, including 200 yards run of trained Plum trees on walls; Apricots are a very thin crop; Peaches and Nectarines, which rarely fail to produce good crops with us, are all bearing badly this season. Pears are almost a total failure, while Cherries are but half a crop. Small fruits are plentiful. The Strawberry crop was a good one, but we were obliged to protect our early blossoms from frost. Our soil is badly suited for fruit culture, being of a light nature and resting on gravel, it is also very dry. *Geo. Wythes, Syon House Gardens, Brentford, W.*

— Our crops of fruit promised well considering the season, but on July 9 two very severe thunderstorms were accompanied by hail of the size of small nuts, which practically destroyed the whole of the Peaches, Pears, and Apples. Such storms I cannot ever remember having personally witnessed, but it greatly reminded me of what I read of the storm that did so much damage at Barham Court a few years ago. *H. Markham, Wrotham Park Gardens, Barnet.*

— Pears are almost a failure, although the trees flowered well, but easterly winds followed the flowering period and prevailed for some days, and to this cause I attribute the failure more than to the frost. Cherries this year escaped injury and are excellent, although last season the crop of these fruits was spoiled by the winds. Apples are good, although the crop is not heavy. Bush fruits are extra good and clean. Our Strawberries escaped the frost that was so much complained of elsewhere. The soil is shallow, resting on gravel. *James Hudson, Gunnersbury House Gardens, Acton, W.*

— The fruit-crops in this district are, on the whole, a fair average, and but for the frosts on May 21 and 22 would have been fully up to those of last season. The trees are healthy and clean. Most of the soil about here is a clayey-loam. *W. Watson, Harefield Place Gardens, Uxbridge.*

— The fruit-crops in this district are all below the average. Plums vary greatly; in some places they are heavily cropped, whilst in other districts large tracks of Plum-trees are bare. The Apple-crop is the best, but that of Pears is very light everywhere. Our soil is a good holding loam on gravel. *W. Bates, Cross Deep Gardens, Twickenham.*

— There was every promise of a good fruit year during April and early May, the blossom on the Plum, Pear, and Apple trees being abundant; but the sharp frosts on the nights of May 22, 23, and 24 completely changed the outlook. We registered 7° of frost on May 22, which destroyed the early Strawberry bloom, and Apples, Pears, and Plums all suffered severely; while Runner Beans and Potatoes were cut down to the ground. Our soil here is light loam overlying the gravel. *James Hawkes, Osterley Park Gardens, Isleworth.*

SURREY.—The frost of May 23 totally destroyed our fruit crop. On the exposed thermometer we registered 10° of frost. *S. T. Wright, R.H.S. Gardens, Wisley, Ripley.*

— Some varieties of Apples, including Warner's King, are very fertile; others, such as Lane's Prince Albert, have not a fruit on the trees. *W. Wilks (Rev.), Shirley Vicarage, Croydon.*

— In this district the fruit crop is very disheartening after such a grand promise early in

the season. Even Apples developed a fair amount of blossom, but Apples, Pears, Apricots, and Peaches and Nectarines are all very much below the average. Dwarf standard Plum-trees are carrying a crop, but on trees trained on walls the crop is thin. Damsons are a heavy crop, and Cherries are very good in this respect. Strawberries were very good where they escaped the late frosts. Gooseberries and other small fruit are all satisfactory, with the exception of Black Currants. *C. W. Knowles, Bagshot Park Gardens, Bagshot.*

— The fruit crops in this neighbourhood in the early spring were most promising, but 10° of frost on May 22 proved disastrous, in consequence of which Plums, Apples and Pears suffered severely. Our soil being of a light sandy nature resting on a bed of pure sand, proves very trying for fruit trees in a dry season like the present. On our ground rain is required about every ten days in order to keep the soil in anything like a moist condition. Raspberries and Gooseberries have been very good, but Strawberries have been very poor, with the exception of Latest-of-All, which was very good up till July 18. *W. Honess, Cobham Park Gardens, Cobham.*

— All classes of fruit trees flowered splendidly this year, but what promised to be the finest crop for years was spoiled by the frosts which occurred on May 23 and 24, when a great part of the flowers and fruit of Apples, Pears, Plums, Damsons and Strawberries were completely destroyed. Apples are swelling exceptionally well. Trees of the varieties Lane's Prince Albert, Warner's King, Bess Pool, Tower of Glamis, Stirling Castle, Hornead's Pearmain and Mère de Ménage have fair crops; which also applies to such dessert varieties as Cox's Orange, King of Pippins and Ribston. Pears are almost a failure. Our soil is of a sandy, sterile nature, and dries quickly. *C. J. Salter, Woodhatch Lodge Gardens, Reigate.*

— Although the district of Kingston, Surrey, is largely on porous sand, stiff soils are found in places. The general fruit produce, so far as Apples, Pears, and Plums are concerned, is a very poor one, Pears, including common varieties that are usually free croppers, being exceedingly scarce. Here, as elsewhere, the frosts of May were the primary cause of the scarcity of fruit, and even where there did seem to be a fair set, the fall of fruit later was exceedingly great. In some cases Plums are plentiful, but such crops are the exception. *Alex. Dean, 62, Richmond Road, Kingston-on-Thames.*

— The fruit crops here are very light in numbers, with the two exceptions of Cherries and Apricots. Late frosts proved most disastrous. Apples are practically absent, while Pears are represented by a few mostly deformed fruits. Crops of Plums are under average, but the fruit promises to finish well. Peaches and Nectarines are much under the average. Apricots are an average crop, and judging by the present state of the trees should finish well. Small fruits are under the average, but some are very good in quality, especially the Loganberry and Raspberries. Strawberries are a very light crop, with the exception of late varieties, by far the best being Givon's Prolific. Walnut-trees suffered severely from the late frosts; a few trees on the hillside in sheltered positions are carrying a fair crop. Cob-nuts are plentiful. *Geo. Kent, Norbury Park Gardens, Dorking.*

— The soil in this district is of a light nature. With the exception of small fruits the fruit crops are much under the average in bulk. *W. C. Leach, Albury Park Gardens, Guildford.*

SUSSEX.—Owing to the late spring frosts the fruit crops are thin in bulk. Apples and Pears are under the average, but are of good quality. Among Apples, Keswick Codlin, The Queen, Yorkshire Beauty, and Bramley's Seedling (on espalier-trained trees) have good-sized fruits. On old orchard trees there is no fruit, but young trees are carrying a small quantity. Gooseberry-bushes have always a good crop here, which also applies to other bush fruit and Strawberries. Loganberries, American Blackberries, and Wineberries are very useful as a succession to Raspberries, which last-named have been very good. Our best Strawberries are Royal Sovereign, President, Fillbasket, Climax, and Waterloo, which are suited to our heavy soil. Crops on wall trees, such as Peaches, are very thin. Plums are about an average; all the Gage type do well with us. Apricots can only be grown under glass here. Figs on walls finish a good late crop, Brown Turkey being the best. The soil is too cold for Cherries without being prepared especially and drained. Morello do well, and are carrying a heavy crop. Cordon Pear-trees on arches and on walls are carrying under an average crop, but the fruits are of good quality. Potatoes in some places here have the blight, but up to the present we are free of this disease. Sharp's Victor, May Queen, Ashleaf, Royal Kidney, British Queen, Up-to-Date, and Factor are among our best varieties, while Evergood, Northern Star, and Discovery are a failure. *A. B. Wadds, Paddockhurst.*

— With the exception of Apples there was every prospect of a bountiful crop of fruit this year until the severe frosts in the early part of May, which gave almost everything a severe check, especially Black Currants. Damsons are very plentiful. Our soil is variable, from light sand to stiff clay, with a subsoil of sandstone, much impregnated with iron. *Alex. Reid, Possingworth Gardens, Cross-in-Hand.*

— The prospects of a good general crop of hardy fruits were never better than they were this year, but they were ruined owing to continued north-easterly winds and late frosts, which caused much of the blossom to drop prematurely. The soil here is light and thin, overlying chalk. *E. Burbury, Arundel Castle Gardens, Arundel.*

— The fruit crops in this district are about average in quantity, the fruits being of very good quality. The soil is a poor and hungry sandstone. *Wm. Brunsdon, Brumbletye Gardens, East Grinstead.*

— Owing to the very late frost of May 23, which registered 7°, Raspberries, Strawberries, Quinces, and most other fruits were greatly injured, two-thirds of the Strawberry-crop being frozen outright. *G. Griggs, Ashburnham Place Gardens, Battle.*

— Most varieties of Apple-trees here are sparsely cropped, no doubt owing to the very heavy crop of last season, as there was a scarcity of bloom. Pears are quite up to average in bulk, and of good quality, though many fruits have dropped. The show of blossom on these trees was remarkable, and generally resulted in a good set. Among the best croppers are Williams' Bon Chrétien, Beurré Diel, Duchesse d'Angoulême, Doyenne Boussoch, Josephine de Malines, Jargonelle, Bergamot d'Espéren, &c. Some early varieties, notably Beurré Giffard, Triomphe de Vienne, though abundantly flowered, have not a single fruit, even on walls. Plums are variable; the fruits still continue to drop, though what remain are of good size. The best crops are on trees of Cox's Emperor, Victoria, Czar, and Kirke's; Greengages are very thin. Cherries are very good, though much fruit fell

during the stoning period, and the large rainfall the last few weeks has caused the fruits to split on a large scale. Governor Wood, May Duke, &c., are carrying very heavy crops of fine quality. Gooseberries and Currants of all varieties are heavily cropped, the fruits being of good size and quality. Strawberries were very good, but beds in exposed situations suffered from the severe frosts in May, though sheltered ones escaped entirely. Among those varieties with heaviest crops may be mentioned Monarch, Auguste Nicaise, Latest-of-All, Waterloo, and Eleanor. The soil is a heavy loam, overlying stiff yellow clay. Chas. Jones, *Ole Hall Gardens, Burgess Hill.*

— The soil here is a stiff loam, bordering in some places on clay. The situation varies greatly, the ground being undulated. Where the soil is fertile Apples do fairly well, but most varieties suffer much from canker. Pears are an uncertain crop, the trees being liable to canker, especially the more tender kinds. Plums and Cherries as a rule do well, but Peaches and Nectarines are usually cut up by the late spring frosts. H. C. Prinscp, *Buxted Park Gardens, Uckfield.*

WILTSHIRE.—The prospects of good fruit crops in this district were exceedingly favourable until the frosts that occurred on April 22, 23, and 24, and again on May 22, 23, and 24, when the crops were ruined. The soil in this district is composed of friable, marly loam on chalk, and is very shallow in depth. The orchards generally are situated in low-lying, damp valleys, in which positions the frosts in the spring seasons are often more severe than on the surrounding hills. Thos. Challis, *Wilton House Gardens, Salisbury.*

— Owing to 10° of frost at the latter end of May, Apple and Strawberry blossom suffered terribly, and everything being extremely wet the damage was intensified. Our soil is somewhat heavy, of fairly good depth, on a stiff yellow clay subsoil. H. Gandy, *Longleat Gardens, Warminster.*

— The fruit crops in this district are decidedly under the average, and poor in quality. The frosts of May destroyed what promised to be a good fruit season. Strawberries especially suffered. The only fruit crops which have been at all satisfactory are Gooseberries and Currants. It is rather early to speak of the quality of Apples, &c. W., *Malmesbury.*

— Apples on espalier and pyramid trees are of good quality, the trees bearing freely; but orchard trees are, on the whole, sparsely cropped, and the fruit is of very poor quality. Pears are few in number, but Peaches and Nectarines are a good crop. All bush fruits are excellent. Strawberries have been under the average. The sharp frosts of May 22, 23, and 24, when we registered 8°, 10°, 9° on successive nights, ruined most of the fruit blossom. The soil of the district is mostly of a friable loam, with either a chalky or a gravelly subsoil. S. W. Tucker, *Longford Castle Gardens, Salisbury.*

(To be continued.)

PLANT NOTES.

CLERODENDRON TRICHOTOMUM.

This beautiful hardy Japanese shrub is at present very fine in these gardens, and is laden with its peculiarly scented blossoms. It thrives well in any good soil, but prefers one of sandy peat. For planting on the margin of a shrubbery it has no equal, as with a suitable background the large, dark green leaves of the plants, topped with the trusses of white flowers, make it particularly effective, and it will continue to flower well into September.

BERBERIDOPSIS CORALLINA

is also at present a charming sight, growing on a north wall. It is perfectly hardy with us, and is

covered with trusses of coral-like flowers. If planted against a house where it could be given plenty of room, the effect at this season of the year would be excellent. It thrives in a well-drained, peaty soil, and should be given copious supplies of water during the summer months. Grown in company with *Tropaeolum speciosum*, which is also laden with thousands of blossoms, it furnishes a grand sight.

LAPAGERIA ALBA AND L. RUBRA SUPERBA

are also hardy here, and have this season made growths 14 feet in length. They are planted against a north wall, and are now just commencing to flower. These same Lapagerias were in full blossom during last December, and are again looking very promising. They receive no protection whatever through the winter, but must be carefully watched during spring or slugs will destroy the young growths as fast as they develop. A. C. Smith, *Lydhurst Gardens, Haywards Heath, Sussex.*

The Week's Work.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Antirrhinums.—Cuttings of these may now be inserted.

Colchicums should be planted not later than August. They prefer a sandy soil and plenty of moisture, consequently they are adaptable for planting in the grass by the margins of streams, &c. *C. autumnale* and its varieties are largely grown. *C. speciosum* and *C. Sibthorpii* are good autumnal bloomers, and suitable for planting on the rockery.

Crocus speciosus is probably the best species of the autumn-flowering varieties, and does well on banks, &c.

Amaryllis Belladonna.—Bulbs that are planted in the borders in front of houses and in other dry situations will soon be showing flower-spikes, and should receive applications of weak manure water whenever the weather is at all dry.

Lilium speciosum, *L. Batemanni*, *L. Henryi* and varieties of *L. tigrinum* will be benefited by a mulching of well-decayed manure. They should also receive sufficient moisture at the roots. The same treatment if given to *Montbretias* will forward the development of the flower-spikes.

The Shrubbery.—*Clethra alnifolia* is a compact deciduous shrub, bearing at this season numerous spikes of fragrant white flowers. It thrives well in almost any position. The various species of *Ericas* are looking gay at the present time. They should receive suitable waterings whenever necessary. *Erica vagans alba* develops into a fine bush. *E. vulgaris* and its many varieties are all suitable as border plants. *Daboecia (Menziesia) polifolia* and the white variety are distinct shrubs, flowering for many weeks during the summer-time. They thrive well on banks and in sunny places if planted in sandy peat. They can be increased by layering and by cuttings inserted in a cool frame. Pampas Grass (*Cortaderia argentea*) is now rapidly growing. It requires plenty of water to perfect its graceful plumes. *Kniphofias* in shrubberies and in borders should also be given plenty of water.

The Rockery.—*Meconopsis cambrica* fl. pl., which grows well in shady places, continues flowering all through the summer-time. *Campanula turbinata Isabel* is a handsome variety of compact habit, freely producing flowers of a rich violet-blue. *C. garganica hirsuta*, *C. muralis*, *C. carpathica Riverslea Gem*, are other species in flower at the present time. *Dracocephalum speciosum* is a showy-looking plant with pinkish-blue flowers.

The Wild Garden.—There are many places in the wild-garden that are only suitable for plants of a persistent character. The New Zealand Burs (*Acæna*) are suitable for many aspects, as they rapidly cover a large area; this is particularly true of *Acæna sarmentosa*. A. Buchanani has very distinct foliage of a pea-green colour; A. pul-

chella and *A. inermis* have bronzy-grey foliage; the latter variety is useful for planting in the vicinity of steps, over which it can ramify. *Asarum europæum* is a hardy creeping plant; *Anthemistinctoria* furnishes a wealth of flowers even in the driest situations. *Arenaria balearica* is useful for clothing rocks, &c. *Cistus*es prefer a dry, sheltered bank. *Cotula squalida* has fern-like foliage, and grows rapidly in shady damp ground. *Crucianella stylosa* will thrive in poor places. *Epimediums* prefer a semi-shaded position. *Hypericum*, *Linarias* and *Lippia repens* are all suitable plants for the wild garden. *Petasites fragrans* is an excellent subject for naturalising in the roughest of places. *P. japonicus giganteus* develops very large leaves and does not require any particular soil. *Polygonum vacciniifolium* is a fine creeping alpine suitable for any situation, as are also *Stachys lanata* and *Symphandra Hoffmanni*. *Thymus Serpyllum* and its varieties delight in dry sunny places. They are excellent for planting round about steps.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Anthuriums.—Plants that have remained undisturbed for some time and that would now be benefited by repotting should receive attention at once, in order that they may become again established before their flowering period. Overpotting the plants must be strictly avoided. Unless they are in very vigorous health, the same sized pots should be used again, it being necessary only to furnish some good fresh compost, which must be carefully worked among the roots. See that the pots are thoroughly cleansed before use, and furnish clean drainage for about half the distance up the pot, using for the purpose broken crocks and charcoal in equal quantities. The compost should consist of lumps of good turfy-peat, sphagnum-moss, and charcoal, the whole being well mixed together. When potting endeavour to keep the crown of the plant well above the rim of the pot. At the same time work the compost carefully between the roots, and when this has been gently pressed with the fingers the plants should be secured with a stake in the centre. A layer of sphagnum-moss pressed on the soil completes the operation. Shade the newly-potted plants from the sun's rays, and give an occasional syringing of clear water overhead to keep the plants from flagging, but great care must be exercised that an excess of moisture at the roots be not allowed.

Poinsettias.—Sturdy plants from the earliest-struck cuttings will require to be gradually hardened and ripened to produce good bracts. The shading should be gradually removed, and finally dispensed with altogether. Allow a free circulation of air to pass between the plants. Liquid manure judiciously applied will be of great benefit, and once a week a light dusting of Clay's Fertiliser should be given. Later-struck cuttings will need to be kept in a somewhat closer atmosphere until they are well rooted, but they must not be allowed to become drawn or weakly.

Euphorbia jacquiniiflora.—These should enjoy the benefit of full exposure to the sun's rays as they show signs of maturing, but this must be effected gradually in order to avoid scorching. Give liquid manure regularly and often to the roots in a well-diluted form.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Pol Figs.—The wood of the earliest forced plants should now be well matured, and the trees in a fit condition for being placed out-of-doors in a sunny position. Less water at the roots must be given as the wood ripens, but syringe freely the trees on bright days until the leaves fall. Top-dress or pot any plants that require it as soon as the fruits are all removed. A suitable compost for the purpose consists of a mixture of good loam, wood-ashes, lime-rubble, and bone-meal. Later trees which are now developing their fruit should be liberally fed, and the house in which they are growing freely ventilated during the early part of the day, closing the

structure early in the afternoon, with abundance of atmospheric moisture present.

Planted trees will require careful attention as soon as they are cleared of fruit, in order that the young growths may properly mature. Remove any new fruits that develop, and also any useless shoots, in order to allow light and air to pass freely amongst the plants. Afford full ventilation to the house, and syringe the trees freely with clean water to eradicate red-spider. Reduce the supply of water at the roots in proportion as the wood shows signs of ripening.

Figs in Cool-houses.—Plants in full bearing need careful syringing and watering. The former should be done on bright mornings only, while the damping of the borders must be regulated by the state of the weather outside. Feed liberally as the fruits ripen. If the trees are not growing satisfactorily, and the borders are in a sour condition, lift the roots to within 2 feet of the stem, and replace the old soil with some good fresh compost, at the same time shortening the strong roots and spreading the fibrous ones nearer the surface. Thoroughly water and syringe the trees daily for a few weeks after this is done.

Strauberies.—Plants that were potted last month will now be growing freely, and should be allowed plenty of room for the full development of their foliage. Plants growing in small pots or that have filled their pots with roots may have a little weak liquid-manure water applied twice weekly. Care, however, must be exercised in the use of stimulants, or gross growths will be encouraged late in the season that will not mature. This especially applies to plants that were given a rich compost. Keep the pots clear of weeds, and remove all runners as soon as they appear, also any small crowns that are not required. Late runners which still require potting should be attended to at once, and afterwards placed in the shade for a few days until new growth commences, when they must be moved into the open and treated as advised in a previous Calendar.

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Gathering Seeds.—Choose the earliest favourable opportunity for seed gathering, when it is ascertained that they are well matured, a bright clear day being the best for the purpose. Expose them fully to the sun until they are perfectly dry, while to retain their germinating power they must be stored very carefully.

Earthing Celery.—Fine weather should be chosen for this operation, when the soil is in good condition. See that there is no lack of water at the roots, and before earthing apply a suitable dressing of fine powdered lime round about the plants, the earliest of which will now be almost if not quite fully developed. Injury is oftentimes caused by too early earthing, the object of which is to keep the stems in perfect darkness. Use finely-broken soil for the purpose, and while the work is proceeding give occasional dustings of lime to destroy any insects hidden in the soil, as nothing is more objectionable than the marks of insects upon an otherwise perfectly developed leaf-stalk. Draw the soil equally round about the plant, otherwise a deformed growth will be the result.

Cauliflowers.—The number of "blind" plants in every variety of both the summer and the autumn kinds has far exceeded the average, teaching the necessity for keeping a good store of surplus plants in the seed-beds. A still better practice is to make small and frequent sowings to fill up the blanks. This danger may be checked if detected in time by sprinkling the crowns and leaves early in the morning with soot when they are damp with the dew. To ensure Cauliflowers for cutting by about May, make several sowings during September, and keep the plants stiff and sturdy by cool and open treatment. Equally good results can be secured by sowing the extra early varieties early in the year.

Mushrooms.—*Out-of-door Beds.*—September is a good time to collect horse-droppings for beds intended to produce Mushrooms during the spring months. The rank heat must be allowed to escape by frequently turning the manure.

The beds should have a fairly dry foundation, a position against a north wall being suitable. They should be made about 4 feet wide and 3 feet high, consolidated and spawned just below the surface when the heat has declined to 75° or 80°, and afterwards covered with a layer of soil 2 inches in depth. Make the surface firm and smooth with the spade when the soil is sufficiently moist to be pressed. The bed should be well thatched with clean straw at least 2 feet in thickness, over which strong garden netting should be securely pegged down to keep the straw in its place. Another kind of bed may be made similar in form to Potato pits, of the same height and width as the above. Flat beds may also be made out-of-doors with equal success, but to ward off heavy rains and snow it is necessary to have movable covers of felt, corrugated iron, or wood. When structures are provided for growing Mushrooms, the process of preparing and making the beds is the same as advised for out-of-door beds, except that it is not necessary to cover them with litter.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Odontoglossum crispum.—Much has been written at various times on the best method of cultivating this Orchid. Localities, the general environment, description and situation of the houses, differ in so many ways, that oftentimes where the supposedly correct details are carried out failure results from one or many causes that are entirely beyond the grower's control. A friendly tree may in some instances be the secret of success, casting its cooling shade upon the house at a time when shade is most needed. A high wall may have its advantages in the summer time, but may prove a stumbling-block to success in winter. One grower favours a structure fully exposed, another advocates one in an open position for the dull months, while still another prefers a situation on the north side of a wall during the summer season, and yet a grower, by adopting any one of the above conditions, may fail, because other necessary features are absent. Many amateurs are severely handicapped in growing these plants by being compelled to grow them in a mixed collection of Orchids, and in striving to do the whole well some are sure to fail. Undoubtedly local influences have a very great bearing on the cultivation of this plant, the skill and experience of the grower being of little avail if these are unfavourable. Next to locality, a suitable structure is a very necessary adjunct. Personally I favour a low span-roofed house situated in the open and facing east and west, so that each part has an equal opportunity of receiving sunlight during the dull season. It should be amply provided with pipes for heating purposes, and be furnished with suitable ventilators in the walls and on either side of the roof, so that they can be used according to the direction of the wind. The floor should be bare of tiles, &c., a layer of coal-ashes being the most suitable material for the purpose. The stages should be of the "double-deck" pattern, that is a lower one covered with ashes or shingle, and an open trellis-work one 4 to 6 inches above. The lower one should admit of the water draining away, and be so constructed that heat and air may circulate upwards. Tanks for the storage of rain-water should be built crossways at the ends of the house. The shading arrangements should be fixed well above the glass and out of the way of the roof ventilators. The chief points to be secured are a light structure sheltered from the north and east winds, but open to all the available sunshine in winter; the means of maintaining a moist atmosphere with free and ample ventilation, and a large supply of piping so that heat may be steadily evolved.

Potting materials for *Odontoglossum crispum.*—Great diversity of opinion also exists on this subject, but in my opinion good results can be obtained from most of the usual means employed, provided other conditions are favourable. The treatment must be in accordance with the materials employed, and must be persistently and consistently pursued throughout the year. It has become evident from the use of leaf-soil that if a return be made again to peat and moss,

a greater depth of material should be afforded than formerly, when the pots were almost filled with crocks. The use of Fern-rhizomes for drainage purposes has proved very satisfactory with many growers, but so far as my personal experience goes it has been practically a failure. I hope to deal further with this subject in next week's issue.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Protecting Fruit from Birds.—Immediately fruit begins to change colour and the first stage of ripening commences they are pounced upon by birds, to obviate which protection by fish-netting becomes necessary. Blackbirds are the chief depredators just now, although later on starlings will soon devour all the fruit in an orchard if not scared off by powder and shot. Blue-tits, although great insect-devourers, damage much fruit by making a small hole just by the stalk, causing the fruit to fall.

Pears.—The earliest varieties will soon be ripening, the first to mature being Doyenné d'Été, which is very fertile when double grafted on the Quince stock. Citron des Carmes ripens next. It is a valuable early French dessert variety of good flavour. Jargonelle, Beacon, and Beurré Giffard will all ripen during the present month. Jargonelle should be gathered before it is fully ripened, otherwise the true flavour will be lost. Protection will be necessary to ward off birds which have a special liking for these fruits. They usually injure the choicest fruits by pecking them near the stalks, which allows an opening for wasps and flies to further the damage. The only perfect method of protecting Pears is to envelop them in muslin bags. A free use must also be made of the gun to scare these robbers, taking care the shots do not enter the branches of the trees, as the injury caused to the shoots invariably results in canker. Mid-season and late kinds should have every attention given them. In those districts where the crop is satisfactory the present warm summer should produce fruit of excellent quality. Trees growing on the Quince stock, which naturally require a moist soil, should be well supplied with water at the roots. The size and quality of the fruit will depend greatly on the attention the plants receive with regard to manual feeding and artificial stimulants at the present time. Trees growing in light soils will be much benefited by a mulching of manure and a heavy watering once a week. Young shoots which were pinched back earlier in the season will have made a secondary growth. These should be again pinched back to two leaves.

Planting Strawberries.—Where the ground has been manured and dug as previously advised and the plants are in readiness, planting may be commenced without delay, as by early planting a crop is secured next season. A succession of fruit can be obtained by planting early varieties in a warm south border, the main crop varieties in the open garden quarters, and the later kinds in north, east, or west borders. Much depends on the nature of the soil whether it should be firmed. Soils of a retentive and water-holding nature will only need the soil firmed about the roots of the plants, while light soils will be benefited by being consolidated all over. Plants intended to occupy the ground for two seasons only should be planted closer together than those intended to remain for a longer time. In the former case 2 feet from row to row and 18 inches between the plants will suffice, but in the latter case the distance should be 2 feet 6 inches and 2 feet respectively. Varieties of weaker growth may be planted closer. Before proceeding with the planting see that the plants are well saturated with water. Do not cover the crowns when planting, but place the "balls" sufficiently deep that the plants will not get dried through by the sun and wind. Should dry weather prevail after planting, frequent waterings must be given. Much assistance is afforded the plants by a mulching of either hotbed manure, long litter, or even mown grass. Any "runners" or flower-stems which develop must be rigorously removed, and every encouragement given the plants to perfect their crowns for next year's fruiting.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does no undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

Illustrations.—The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, AUG. 26—Hawick Flower Show.

TUESDAY, AUG. 29 { Royal Horticultural Society's
Committees Mect.

WEDNESDAY, AUG. 30—Bath Floral Fête (2 days).

SALES FOR THE WEEK.

MONDAY AND WEDNESDAY NEXT—
Sale of Dutch Bulbs at Stevens's Rooms.

MONDAY TO FRIDAY NEXT—
Dutch Bulbs in large variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 10.30 o'clock.
(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—60° 2'.

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, Aug. 23 (6 P.M.): Max. 66°;
Min. 52°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, Aug. 24 (10 A.M.): Bar., 30.1; Temp., 65°. Weather—Bright and fresh.

PROVINCES.—Wednesday, Aug. 23 (6 P.M.): Max. 62°; Cornwall; Min. 55°, N. Ireland.

again, a wide field is opened to the *Cypripedium* hybridist, who will no doubt in a few years produce further charming results.

On April 25 of this year two plants were received at Kew from the Botanical Gardens, Calcutta, and which were believed to be *C. Fairieanum*. It was necessary to see the flowers before the species could be absolutely determined. This has now been accomplished by the production of blooms on the specimens which were the first to reach this country after its rediscovery (see fig. 57).

The plant now flowering is one with five growths and two flowers. The second and larger plant is developing five blooms. In general appearance it resembles a small-leaved *C. insigne*, the largest leaf being

FIG. 57.—*CYPRIPEDIUM FAIRIEANUM*.
Sketched at Kew by Miss Smith, August 22, 1905.

7 inches in length and 1 inch in breadth. The slender, hairy scape is 10 inches in height; the prominent and charming dorsal sepal is $1\frac{3}{4}$ inch in length by $1\frac{1}{4}$ inch in breadth, having a white ground beautifully veined with violet-purple, with brownish-green veins near the centre, and whitish hairs around the margin. The petals have the characteristic droop and upward curve at the tips; they are $1\frac{1}{2}$ inch in length, and have a white ground colour streaked with purple and yellow; the upper margin is much undulated and covered with prominent purple hairs. The pouch is rather small, greenish-brown in colour, veined with brownish-red, and covered with short hairs. The ovary is $1\frac{1}{2}$ inch in length, very slender, and densely covered with dark purple hairs.

As imported plants of *C. Fairieanum* are now in many collections, it will be useful to record the treatment afforded the Kew

plants, under which they have become established and grown with all the vigour of *C. insigne*. On arrival the plants were placed in pans, the old roots being covered with potsherds to within an inch of the top of the pan. They were then placed in a shady, moist corner of the stove, in a night temperature of 65°, and a day temperature of 75°. Here they soon developed strong healthy roots from the base of the growths, and commenced to push new leaves and new growths. When fairly well rooted the pans were filled up with a mixture in equal parts of fibry yellow loam, peat, moss, and Oak-leaves. They rooted freely into this mixture, and made good growths, showing the buds on July 1, the flower expanding on August 16. An intermediate temperature is one most likely to suit this species best.

It is figured in the *Botanical Magazine*, t. 5024, from specimens from Mr. REID, of Burnham, Somersetshire; and also in WILLIAMS' *Orchid Album*, vol. 2, t. 70. It was originally described by Dr. LINDLEY in our columns, 1857, p. 740.

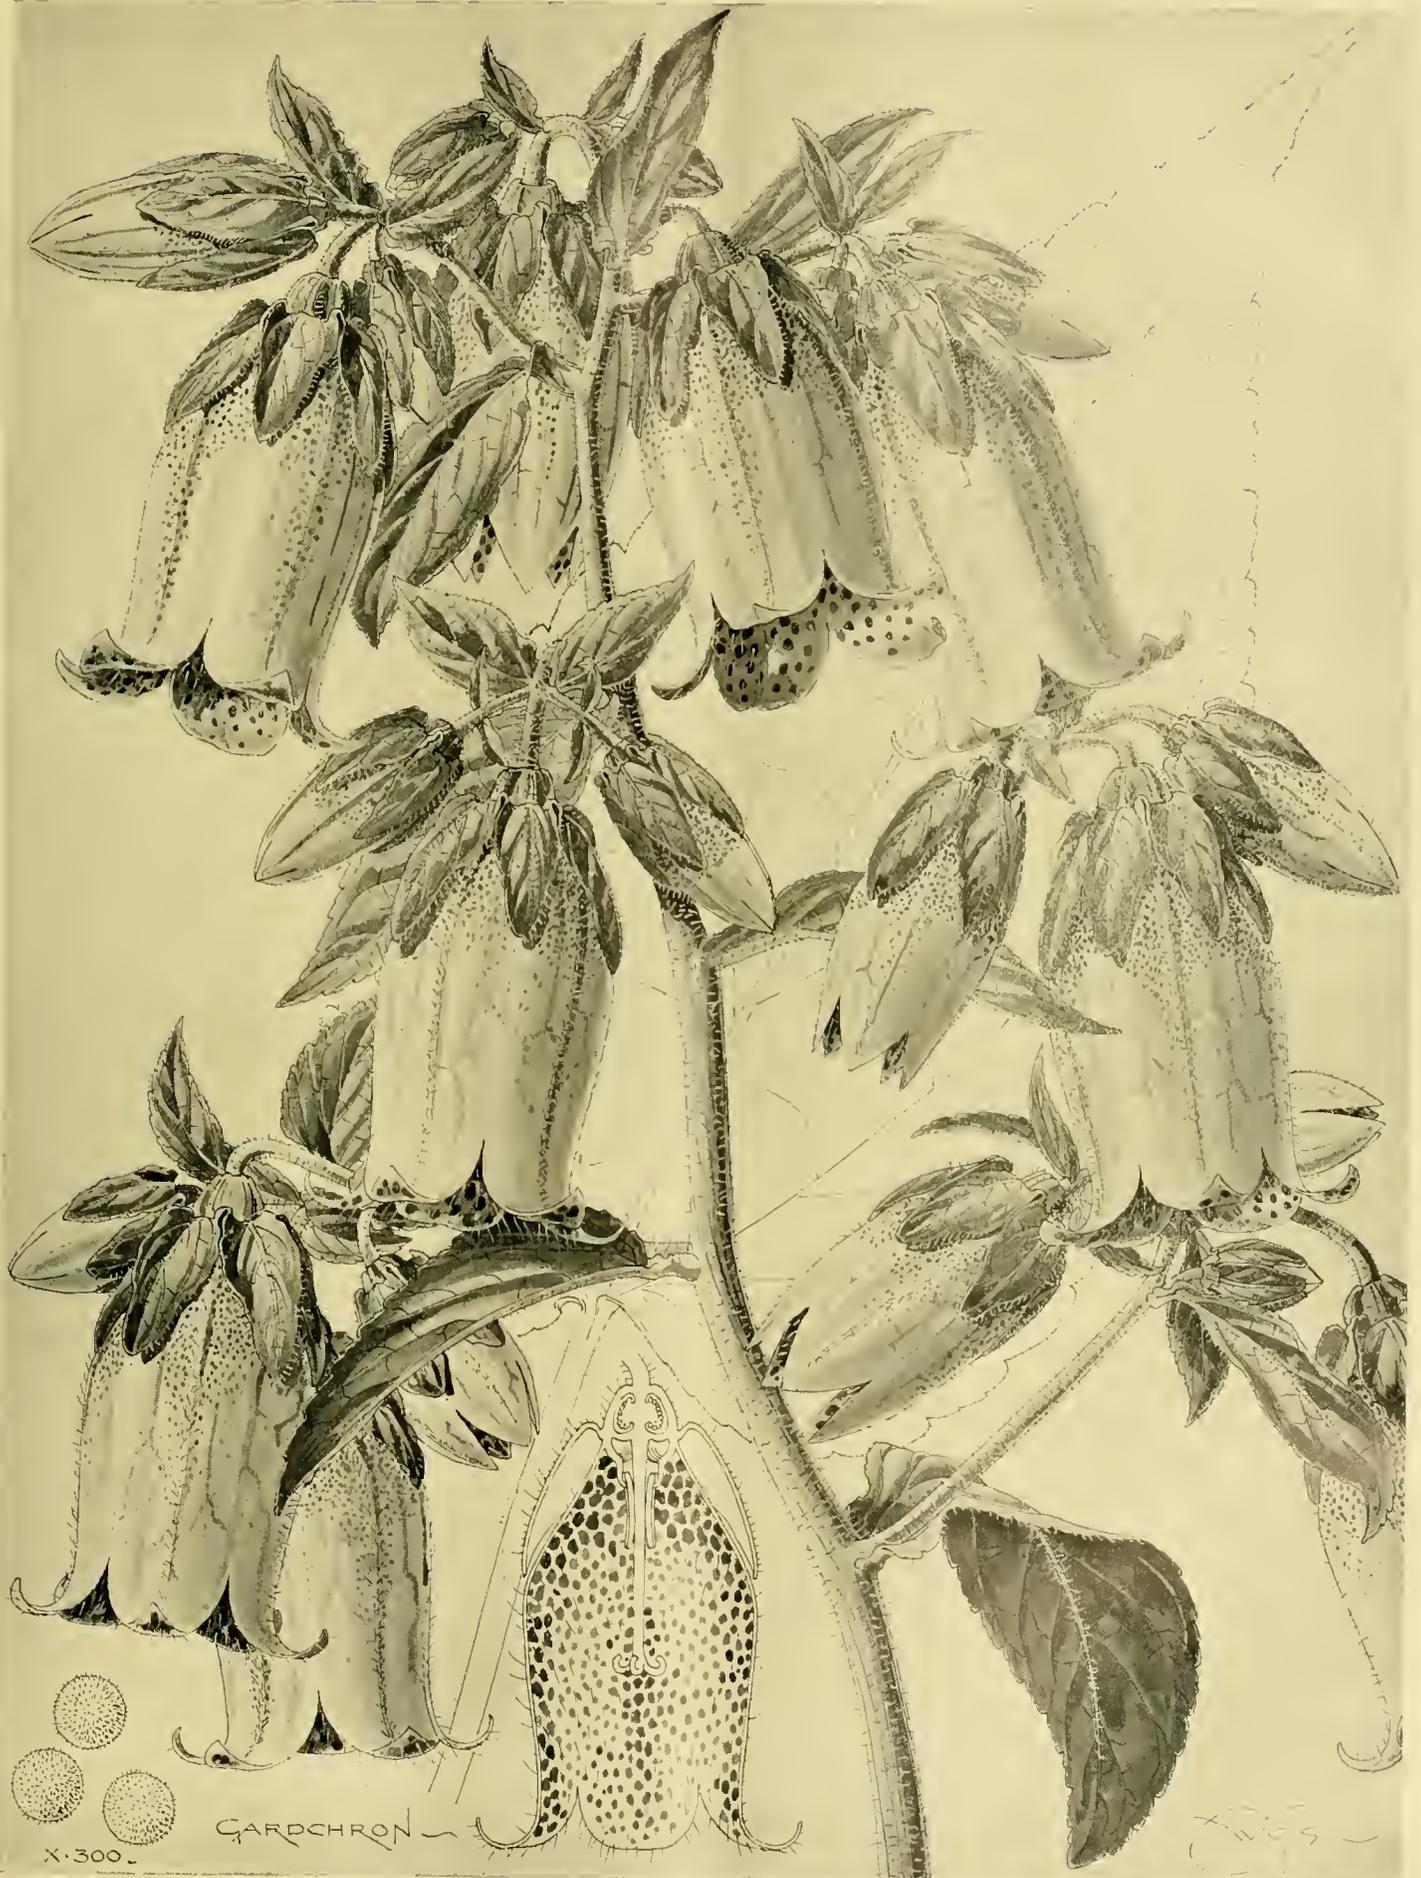

It is not only a sad thing, Richard Dean, but one difficult to realise, when one who has been specially active for something like fifty years is taken from us. Nevertheless, those who lately saw the attenuated frame and enfeebled condition of RICHARD DEAN must have felt that the end was near, and now that it has come they must, with all their regrets, feel a sense of relief that the labourer is at rest. For labourer he was to the very last! His energy and spirit, though subdued, could not be quenched while life remained, and it is but a very short time since he was present at the Floral Committee of the Royal Horticultural Society, and only a week or two ago he was present as a judge at the Wolverhampton and Boston Shows, though in a sad state of physical debility.

It has been said of RICHARD DEAN that he was a born secretary, and few indeed have been the societies, the associations, and the flower shows within the metropolitan area, and even beyond it, with which RICHARD DEAN has not been connected. His mastery of detail, powers of organisation, and indefatigable industry were invaluable to such societies. Was a new one to be formed, an old one reorganised, a complicated and involved procedure to be simplified and made straight, it was RICHARD DEAN who was naturally appealed to to do what was necessary. To the last he remained the Secretary of the National Chrysanthemum Society, and the popularity and success of that body are due very largely to his efforts. There has indeed been scarcely a horticultural "movement" of any kind during the last forty or fifty years in which RICHARD DEAN has not taken an active and generally a prominent part.

Our own knowledge of him dates from 1866, when he was appointed Assistant Secretary to the International Horticultural Exhibition held in that year. The executive details preparatory to that great gathering were for many months largely entrusted to him, and towards the last we well remember the night and day work that fell to his share. Two or three only remain of those who carried that memorable meeting to its triumphant success. As to its results we need only say that the Gar-

Cypripedium Fairieanum. WE have now the pleasure of recording the fact that a vigorous plant of this famous species is in flower at Kew. The plant has for a long time defied all attempts to rediscover its native haunts, notwithstanding the fact that the first few specimens were generally believed to have been imported from Assam.

As almost all orchidists are aware, the original plants were purchased at Messrs. STEVENS'S Sale Rooms in 1857. Mr. FAIRIE, of Liverpool, was one amongst several buyers who obtained examples that were included in a collection of Orchids from Assam. He was fortunate enough to flower his plant first, and it was subsequently named after him. Since that time the stock under cultivation in this country had gradually dwindled down until only the small specimen in the collection of Sir TREVOR LAWRENCE was left. How such a state of affairs could possibly have happened is rather difficult to understand, seeing the vigour that the Kew plants exhibit; but the employment of too much heat in its culture is the generally accepted theory, though the extensive employment of the plant for the production of hybrids may possibly have had something to do with its almost total disappearance. The distinct dorsal sepal and the curious drooping and curved petals, which the hybridist has linked with the best characters of other species, have been reproduced in a race of wonderfully beautiful hybrids, which are far more handsome than *C. Fairieanum* itself. Now that we have this type to work with

CAMPANULA PUNCTATA, HARDY PERENNIAL, FLOWERS PALE ROSE WITH DEEPER-COLOURED SPOTS.
HORT. BEAMISH.

deners' Benevolent Institution benefited substantially, and that the Lindley Library and the Scientific Committee represent the direct and permanent outcome of the labours in which RICHARD DEAN took so large a part. But he was much more than an executive officer. His knowledge of various branches of horticulture was great; his perceptive and critical faculty so highly developed that his services as judge were in requisition all over the country. He was a member of the Floral Committee of the Royal Horticultural Society from its inception to the present time almost without interruption, whilst he had a general, all-round knowledge of plants and their culture. He had a special acquaintance with what are termed florists' flowers. The mantle of the old florists had fallen upon him. He was, if not quite, yet nearly the last representative of the old school to whom the "properties" of Auriculas, of Tulips, of Carnations, and other "florists' flowers" were as dogmas to be revered and acted up to, in spite of the teachings of evolution, the canons of art, or the "higher criticism" generally, to say nothing of the banter of the profane. And yet, whilst he held to the old with a loving faith, he was far-sighted enough to accord respect to the new, and, whilst retaining his own opinions, to recognise that truth has many facets, and beauty many aspects. This led him to be much more tolerant of the tastes and opinions of others than were some of his predecessors.

Our readers and ourselves have been under great obligations to RICHARD DEAN as a correspondent and reporter during more than four decades. It will be difficult to replace him, and we do but voice the feeling of the multitude of his fellow-workers when we express our deep sense of the loss we have sustained and of our sympathy with those whom he has left behind.

RICHARD DEAN was born on February 1, 1830, at Page's Nursery, Southampton, where his father was foreman for many years. RICHARD was the third of four brothers—WILLIAM, who died a few years since at Birmingham; JAMES, who died in 1856 at Slough; then himself, and ALEXANDER, who is still alive. In boyhood he was initiated into practical horticulture in various local gardens, and specially when he entered the Royal Nursery, Slough, under that famous florist CHARLES TURNER. WILLIAM DEAN was at that time a Superintendent there. RICHARD remained in that nursery for several years. There it was that he gained his first ideas in relation to florists' flowers, which made him to be so great an authority in that department of horticulture. Later he served for some years in the then well-known wholesale seed house of BECK, HENDERSON, & CHILD, and was also for some time with ARTHUR DICKSON & SON, of Chester. In these houses he was enabled to obtain a wide knowledge of seeds and the seed trade, not easily to be obtained. Later on, some forty years since, he became a trader himself, dealing in seeds, florists' flowers, and hardy plants generally, as well as Potatoes, and occupied land for such purposes at Bedfont, Middlesex, as well as at Hounslow. On the death of JOHN EDWARDS he became the Honorary Secretary of the National Floricultural Society, which was ultimately merged into the Floral Committee of the Royal Horticultural Society, of which Committee he was, we believe, the oldest member. That he should be selected as one of the first to receive the Victoria Medal of Honour was natural. In bygone years he was for a long time

Secretary to the Ealing Horticultural Society. With Mr. ALBERT CHANCELLOR, he for several years managed the shows of the Richmond Horticultural Society in its palmy days. He also, under the late Rev. WILLIAM ROGERS, managed the City flower shows, and being a first-rate organiser his services were in wide request for similar duties. So tenacious was he of the responsibilities attached to these requirements that but recently, when physically almost incapable, he journeyed all the way to Wolverhampton to fulfil an engagement. His sole mental pain on his sick bed was the realisation that he had judged his last, and that the work he loved so well was done for ever. His connection as Assistant Secretary with the famous but now almost forgotten International Exhibition of 1866, which proved to be such a great success, is little known to the present generation. His long connection as Secretary with the National Chrysanthemum Society, which he succeeded in steering, with the aid

THE LATE RICHARD DEAN.

of firm friends, successfully through stormy seas into smooth waters, is well known and appreciated. He was one of the foundation members of the Royal Gardeners' Orphan Fund, of the Sweet Pea Bicentenary Celebration, a Secretary of the Hail-Storm Relief Fund, of the Postal Reform Committee, and we know not what beside. Some details of his life-work were given by himself on the occasion of the presentation to him of a substantial testimonial in 1902, and were recorded in our columns on February 8 of that year. It may be the lot of others to live longer, but to few men has it been given to put more work into life than he did. He leaves a widow and four children—two sons, the eldest in South America and the youngest at home, both married; and two daughters at home. The funeral will take place in the Ealing Cemetery on Saturday, August 26, at 5 P.M.

CAMPANULA PUNCTATA * (see Supplementary Illustration).—This is an old inhabitant of our gardens, but is rarely met with, while its merits as an herbaceous perennial are so marked that we are glad to have an opportunity of figuring it. Our illustration was drawn by Mr. WORTHINGTON SMITH from a specimen kindly forwarded from Glouthaune, co. Cork, by Mr. R. H. BEAMISH. It is a somewhat

* *Campanula punctata*, Lamarek. *Encycl.*, 1, 556; *Bot. Mag.*, t. 1793; Hemsley, *Journ. Linn. Soc.*, xxvi., p. 7.

coarse-looking perennial some 2 feet high with large, stalked, hairy, cordate-ovate, acuminate-serrulate leaves; the upper leaves are sessile. Its beauty consists in its pendulous, bell-shaped flowers, each about 2 inches long, white or rose-coloured externally, hairy, and with purplish spots on the inner surface, so that it bears some resemblance to a *Gloxinia*. The pollen-grains, as observed by Mr. SMITH, are globose and pilosulous. The plant is a native of Siberia, and occurs in China, Corea, and also in Japan, whence Mr. BEAMISH obtained his plants. The colour of the corolla varies, being in some cases white or violet; whilst in Mr. BEAMISH's specimens, as before remarked, the flowers are of a delicate rose colour. These variations have caused botanists to consider some of them as distinct species; for instance, LINDLEY, in the *Journal of the Royal Horticultural Society*, i. (1846), p. 232, describes a plant sent home by FORTUNE from China as *C. nobilis*.† More recent students, such as HEMSLEY, in the *Journal of the Linnean Society*, xxvi., p. 9 (1889), place *nobilis* under *C. punctata*.

EXAMINATION IN HORTICULTURE.—The Council of the Royal Horticultural Society has consented to hold a special examination for gardeners employed in the London and other City and Public Parks and Gardens, on Thursday, January 11, 1906, at their Hall in Vincent Square, Westminster. The examination, which will be partly written and partly *viva voce*, will occupy three hours for the written portion, and about twenty minutes for each candidate *viva voce*. Candidates must send in their names at least ten days before the examination takes place to the Secretary, Royal Horticultural Society's Office, Vincent Square, Westminster, S.W., together with an entrance fee of 5s., to defray in part the expenses of the examination.

PARIS AUTUMN SHOW.—As announced in our last issue, the National Horticultural Society of France is now making preparations to hold its autumn show, which will be devoted to Chrysanthemums, fruit, fruit-trees, flowering plants and vegetables, and will be held from November 4 next to the 12th, both inclusive. The site will be the same as that of the late spring show, viz., the large greenhouses on the Cours la Reine. The schedule contains a very large number of classes, and the exhibition promises to be of great extent. In all there are 160 classes, to which works of art, gold, silver-gilt, and silver medals are allotted in considerable numbers. The exhibition is thoroughly international. Artists and the various trades connected with horticulture are also invited to exhibit. In conjunction with this show the French National Chrysanthemum Society will hold its annual Conference, at which papers will be read on various subjects relating to the flower. Of these, a few titles may be given, viz.—"The Use of Chrysanthemums in the Decoration of Gardens and Apartments," "Best means to prevent Damping of the Blooms," "Results of using the 'Repertoire des Couleurs' in describing Chrysanthemums" (a notice of this interesting publication appeared in the *Gardeners' Chronicle* for May 20 last), "Best Composts for Pot Culture," "Packing Blooms," &c. The Jury will be an international one. Chrysanthemum novelties will be especially judged by a committee of nine, three being members of the National Horticultural Society, three being members of the French National Chrysanthemum Society, and the remaining three being foreigners. On November 6 the Pomological Society of France will hold its forty-sixth session under the auspices of the National Horticultural Society, and in view of the great interest of this show we may

† *C. nobilis*, Lindley, ut supra, and in *Botanical Register* (1846), t. 65; *Flore des Serres*, t. 247 et 563; *Revue Horticole* (1845), p. 283.

reasonably expect a very large attendance of visitors. Further particulars can be obtained of the Secretary, 84, Rue de Grenelle, Paris.

"**FLORA CAPENSIS.**"—Another part of this publication has been issued, containing the remainder of the genus *Erica*, by Messrs. GUTHRIE and BOLUS. The species enumerated amount up to 469, together with a large number of imperfectly known species and supposed hybrids. In the earliest volumes of the *Gardeners' Chronicle* (1843) a large number of so-called species were described, many of which were really hybrids, obtained in ROLLISSON'S nursery. Such was the prejudice against hybrids in those days that the new forms were described as introduced species. Mr. N. E. BROWN is responsible for the monographs of several of the smaller genera of the Order.

EXPERIMENTAL BOTANY.—Such extravagant statements have been made in the American Press as to Mr. BURBANK'S doings, that his reputation, which we know to be well merited, is in danger of being injured by injudicious or ill-informed reporters. It is therefore with great pleasure that we read that Dr. HUGO DE VRIES has recently published in Amsterdam his impressions of the Far West, under the title of *Naar California*. The chapter which deals with his visit to LUTHER BURBANK, the famous plant-breeder of Santa Rosa, has been translated and published in the *Popular Science Monthly*. The visit to BURBANK is of unusual interest, inasmuch as DE VRIES was accompanied by two other scientists of world-wide distinction, in whose statements the fullest confidence may be placed. The best way of approaching the study of the variations of plants and their causes is by hybridising, and BURBANK'S farm is the greatest centre in the world for crossings on a scale that can only be described as gigantic. For one of his hybrids he may start as many as 50,000 or 60,000 seedlings. For instance, in the case of a hybrid Raspberry and Blackberry with large berries and big bunches, 65,000 seedlings were cultivated until in full bearing. A few dozens were selected, and then the rest, fruit and all, were consumed to ashes—an *auto-da-fé* which is depicted in one of the BURBANK catalogues; a great loss from a scientific point of view. After the selection of three good varieties, a batch of 15,000 Roses was burned. After fifty of the best of a set of Lily-bulbs were selected, the remaining half-million were destroyed. These figures will give an idea of the scale of the BURBANK experiments. It is well to record that the expenses of this great work are paid for the next decade by funds from the Carnegie Institution.

A WATER-YIELDING PLANT IN THE THANA FORESTS—In a paper read before the Bombay Natural History Society, Mr. G. M. RYAN spoke of the water-yielding plants in the Thana Forests. He says of one of them that "*Calycopteris floribunda* (Nat. Ord. Combretaceæ), called Ukshi in Thana, is one of the most interesting shrubs of the district." In some parts of India it grows as a diffuse, dense shrub; in other places it is scandent; in Thana both forms of it are found. It is very ornamental and bears pale golden flowers. The scandent habit appears to be most natural to it, but is checked by yearly attention. When a climber, the Ukshi "ascends the bole of the tree in a characteristic manner, climbing from left to right. Having established itself in the forest in some spot not far from a tree, it extends its leading shoot till it reaches the branch of an adjacent one. It proceeds to embrace the bole at first in several loose coils, and then to stretch its leader out as if in search of a further exterior support, failing to find which it returns to the original bole and forms three or four constricting coils round it, continuing to adopt the left-to-right habit. Re-

leasing its grasp again, it succeeds by a series of wide curves or swoops in reaching the illuminated heights of the crown of the tree. Here it commences to form a network of branches spreading across the crown, and perhaps overhanging it, until at length some of the branches are suspended in graceful festoons. A tree thus invaded naturally is unable to expand, and eventually dies, but the climber itself does not stop its course." Its lower branches root, and it also reproduces itself by root-suckers. Occasionally a branch will coil tightly round one of the older scandent shoots. The Ukshi stems sometimes attain to a girth of 2½ feet, and resemble ropes loosely stretched between the ground and tree tops, and between trees, and form swings and ladders for the monkeys. The smaller twigs are utilised for native tooth-brushes. "The most interesting characteristic of the plant is its faculty of storing in its climbing stems a liquid resembling water which is commonly drunk by the wild tribes."

THE NATIONAL FEDERATION OF FRUIT AND POTATO TRADES' ASSOCIATION has forwarded to the President of the Board of Agriculture and Fisheries the following memorial:—"We the Fruit and Potato Trades' Associations throughout the United Kingdom, numerous members of the trades affected, and many others, do hereby beg

- (1) to express (a) our appreciation of the action of the Board of Agriculture in causing an enquiry to be made into the Fruit industry of Great Britain, and (b) our anxiety to assist in obtaining practical legislative and other results from the recommendations of the departmental committee which has conducted such enquiry.
- (2) To strongly confirm (a) the importance of quick transit and reasonable rates on the railways of the country, and (b) our belief that, in providing for the latter a more simple and uniform system and a more practical classification are very desirable, and indeed urgently necessary.
- (3) To state that in our experience the protection of traders against the result of the combined action of railway companies has become a vital question in the interests of our trade.
- (4) To offer our services to ensure that the effect of the Report of the Departmental Committee shall be such as to enable Parliament to recognise the great and increasing importance of the fruit and Potato-growing industry, and to pass the requisite statutory enactments; and
- (5) Whilst again expressing our appreciation of what has been done by the Board of Agriculture, to hope that the action of the Board may cause the necessities and requirements of these trades, affecting as they do the whole country, to be better understood, to the advantage not only of the trades and the railway companies, but to the whole population.

THE COMMON SEAL of the National Federation of Fruit and Potato Trades' Associations incorporated for itself and the numerous associations and individuals whom it represents throughout the United Kingdom, hereto affixed in the presence of—

A. ROGER ACKERLEY, GEO. COLEMAN,
Members of the Executive Committee.
EDWARD W. GARDNER, Secretary to the Federation."

BEQUEST TO HORTICULTURE.—According to the *Wimbledon Herald* the late Mr. JOHN INNES, of Merton, has left his house, the Manor Farm, Merton, with eleven acres of ground, to his trustees, upon the following trusts: As to his said house and two acres of ground upon trust to establish thereon a school of horticulture or such other technical or industrial institution as the law will allow to give technical instruction in the principles of the science and art of horticulture and the necessary physical and mental training incidental thereto; to erect suitable buildings and furnish them, and to provide workshops, tools, plant, scientific apparatus, libraries, reading rooms, lecture and drill halls, a swimming bath, and gymnasium. If this may not be legally carried out, then to establish in these buildings a public museum for the exhibition of collections of

paintings or similar works of art, objects of natural history, or of mechanical or philosophic inventions. To lay out land for a park, in which they are to make suitable provision for the practice of cricket, football, lawn tennis, croquet, bowls, the practice of archery, the meeting and drilling of Volunteers, or other military bodies, and for the holding of athletic sports. And further to erect in a suitable position in the said park a pavilion or glass hall, suitable for the giving of musical or other entertainments, and for the practise of indoor amusements, and to transfer the said land, buildings, equipment, &c., to the Charity Commissioners, the local authority, or some other suitable public body. After allowing for the payment of the various legacies to friends and relatives, and reckoning the capital values of the several annuities, the amount available under Mr. INNES' will for the above and other uses would appear to be nearly £200,000.

WEED-KILLER.—A domestic servant was lately charged with unlawfully and maliciously administering or causing to be administered to her mistress and nine other persons a noxious thing known as a weed-killer, and thereby endangering their lives and inflicting upon them grievous bodily harm. Professor SMITH said he had analysed the liquids sent to him, and he found that there was in most of them eighty per cent. of arsenical matter. The so-called "weed-killer" was full of arsenic. It was in a very poisonous form, and its solubility was great.

COLONIAL NOTES.

CAPE OF GOOD HOPE.

I SENT lately a few notes on the Insect Pest Bill, and discussed the question how far it is practicable to clear the insect pests from this land of "sunshine." There is no frost or snow along the coast and a short distance inland. As we have no winter and as this is a warm climate insects spread very rapidly. The Government officials think if they can get the nurseries clean that all will be well; but if clean plants be sent to infected localities, how long will they remain clean?

Among the plants and fruits-trees the importation of which is prohibited into Cape Colony are Apricots, Almonds, Peaches, Nectarines, and Plums—in fact, all stone-fruit trees are prohibited, which means that all stocks for grafting must be raised from seed grown in the country.

Arancarias are not allowed to be imported; they are subject to a scale named *Eriococcus arancarie*; it is a rather large white insect found underneath the leaves. I have never seen it in England, though it is found in America. All the Coniferae are prohibited, but the seed may be imported. Any one importing Grape-vines is liable to a very heavy fine. Ampelopsis and all plants of the order Vitaceæ are also prohibited.

There are many plants in this colony at the present time that would not have been here if they had not been smuggled through by lovers of flowers. All imported plants have to be examined by a Government official, and each plant-case has to be opened in his presence. If he thinks that they are not clean, then he has them fumigated with the vapour produced by pouring sulphuric acid on to cyanide of potassium.

The Natal Government entomologist recommends 2½ oz. of cyanide, 2½ oz. sulphuric acid, and 5 oz. water, the plants to be fumigated for forty-five minutes, that is for 435 cubic feet of space. That is far too strong for Kentias and several other Palms. *Dracenas* and many Ferns will not stand it. When plants have been packed in cases for three weeks and had plenty of sea air, many of them are not in good condition to be fumigated or await the Government official's convenience. Every plant has to be fumigated before it can be sent from this colony into the Transvaal. If the authorities go on at the present rate the nursery trade will have to "close down." *Horticulturist*.

THE SPECIES OF DAPHNE.

(Concluded from p. 153.)

D. pontica, L.—From the Caucasus and mountains of the Euxine. A pretty bushy plant, with ascending or often trailing branches, somewhat like *D. laureola*, but distinguishable by its habit, its wide leaves elliptic-oval, and its yellowish-green flowers, long in the peduncle, gathered in clusters furnished with green, conspicuous bracts. Rare in cultivation [not in England]. It requires partial shade and a calcareous soil. It is quite hardy at Geneva.

D. Gnidium, L.—A fine Mediterranean shrub, 3 to 4 feet high, erect and stiff, with upright branches, furnished above with leaves that are opposite, glaucous, and persistent, in appearance resembling those of *Veronica Traversii*. This was my first impression when in the neighbourhood of St. Raphael I saw these curiously-upright shrubs in the Pine and Oak woods. The flowers are greenish and inconspicuous, but the peculiar foliage makes the plant ornamental for growing in woods. It is scarcely hardy at Geneva, but would certainly be so south of London.

D. glomerata, Lamarck.—This comes from the mountains and alps of the East, especially the Caucasus. It is a small trailing shrub, with dense branches, coriaceous, persistent, oblong-spatulate, obtuse leaves; the flowers are clear rose, in clusters of four to ten, in small, dense heads, accompanied by membranous bracts. It is very rare in cultivation, and seems to be grown with difficulty; it likes partial sunshine.

D. Houtteana, Lindley and Paxton, is akin to *D. Mezereum*, and is considered as a hybrid between this and *D. laureola*. I have never grown it, but it is in the Barres collection.

SPECIES FOR THE ROCK-GARDEN.

Such are the species which will grow in the open borders; as to those for rockeries their number is fewer. There is the most beautiful type of the genus, *D. Cneorum*, L., growing in limestone mountains in Central and Southern Europe. It is a most beautiful and valuable species, found also on the sunny rocks of the Jura, blooming from May to July. In our gardens it succeeds in the heaviest and firmest soils in full sunshine, and blooms from March to May. It grows into large clumps 10 to 12 feet across, and covered with clear carmine-red flowers borne on slender stems with leaves that are persistent, coriaceous, spatulate, and glaucous. The species is deliciously fragrant. There is a variety "major," with fine flowers; another with white-edged leaves; a third "Compacta," and not in cultivation, a form with pure white flowers, which one of the staff of our *Jardin d'Acclimatation* discovered in the Vaudois Jura, which we grafted and increased, but have since lost. We hope to regain it. As to *D. Cneorum* var. *Verloti*, from the Dauphiny Alps, this differs from the type by its pointed linear-elliptic leaves, indented at the top with a mucro, while the leaf of *Cneorum* is linear, oval, rounded at the top without a mucro.

D. striata.—This comes from the Eastern and Lombardy Alps and the Carpathians. It differs from *Cneorum* in its thicker, shorter branches, its narrower leaves, and its glabrous calyx.

D. petraea, from the Alps of Austrian Tyrol and the Dolomites.—It is the smallest *Daphne*, and one of the rarest and most interesting. It forms a tiny, much-branched shrub, with spatulate, linear, dark-green, shiny, persistent leaves; flowers in fascicles of three to five, sessile, clear rose. This plant requires sunshine and calcareous rock. I found it last year on Monte Summano, exposed to the hottest sun on the dolomite rocks with hardly any soil. It forces its roots into the living rock and so finds needful freshness and nourishment.

D. alpina, L.—Grows on calcareous rocks among the Alps, Apennines and Pyrenees. A dwarf, much-branched shrub, the stems bending sharply and dividing; leaves caduceous, glaucous, small; flowers white, fragrant, arranged in small heads at the tops of the branches; berries vermilion-red. It requires full sunshine and a calcareous rock, but is easily cultivated.

D. Blagayana (fig. 58).—From the Styrian Alps and Transylvania. A trailing shrub with spreading branches stretching over the ground; leaves large, oblong-lanceolate, coriaceous, glaucous; flowers large, creamy-white, very fragrant, in large trusses produced in March and April. This plant needs shade and the shelter of a rock, and to spread its branches over the moss and stones.

D. burifolia, Vahl.—From the mountains of Trans-Caucasia and Armenia. A small dwarf shrub with short thick branches; leaves oboval-oblong, very obtuse, whitish beneath and shining green beneath; flowers white, from three to six, in heads, fragrant. I received it once from the garden of the Belvedere in Vienna, but have since lost it.

D. pseudo-Mezereum, Gray.—I must not omit to mention this species from Japan. It originated from *Mezereum*, and the Botanic Garden of Tokyo distributed seeds for several years. It has not yet flowered, to my knowledge, in Europe—at least, not at Barres nor at Kew.

This list includes twenty-seven types of *Daphne*, and five or six varieties, including all that are, so far as I know, in cultivation. There are more than forty different species and twenty varieties known and published. It would be interesting to introduce them into cultivation, as might be done by such firms as those of Veitch and Vilmorin. *Henry Correvon, Floraire, Geneva.*

MARKET GARDENING.

FIELD TOMATOS.

So far the present season has been an ideal one for Tomatos planted out-of-doors, and the plants growing in the open are, as might be

FIG. 58.—DAPHNE BLAGAYANA: FLOWERS CREAMY-WHITE, FRAGRANT.

D. oleoides.—Akin to the preceding species, and from the mountains of southern Europe, from Spain to the East. It is a small shrub with glaucous leaves, larger than those of *D. buxifolia*; flowers greenish-white, fragrant, succeeded by bright red berries. It must be grown on rocks and in full sunshine. The variety *jasminea* from Corsica and the islands of the Mediterranean is distinct, owing to its more pendent flowers.

D. collina comes from the southern Apennines and eastern mountains. It is a pretty little shrub, with oblong-lanceolate leaves, white and hairy underneath, glabrous above; flowers rose-coloured in heads of five to eight, very fragrant. A plant for shady rocks and sheltered nooks. In Geneva it does not survive severe winters.

D. Fionina is a hybrid between *D. collina* and *odora*, which I obtained from Kirkstall, but it did not bear our winters. It is a sturdy plant, and I will try it again at the Floraire Garden.

D. neopolitana × is a hybrid between *Cneorum* and *collina*, which I never saw, but which M. Vilmorin cultivates.

expected, vigorous, clean, and heavily laden with large clusters of good sized fruit, which only requires a few hours' good, steady rain to swell them. The foliage should be kept thinned, that is, the compound leaves should be cut back to two leaflets. All the lateral growths must also be removed in order to allow the clusters of fruit to receive the full benefit of light and sunshine. As soon as the fruits begin to colour they should be gathered, and graded into two or three sizes. The largest fruits should be packed in paper-lined peck baskets, 12 lb. in each basket; following in the same way with the second and third sizes. The label attached to each peck should indicate the quality of the fruit which it contains—first, second, or third, as the case may be.

As to varieties, I find *Comet*, for field as well as for indoor culture, a good grower and a prodigious cropper, the fruit being of a good shape and of a fine colour when ripe. A new variety, *Tamworth Castle*, promises to eclipse even *Comet* and other well-known varieties in fruitfulness, smoothness, and perfect form of the fruits. *H. W. Ward.*

BETTESHANGER HOUSE.

THE village of Betteshanger, near Sandwich, in Kent, is situated in the heart of a purely agricultural district, miles away from any large town, and is one of those delightful old-fashioned places which forms a connecting-link with the past. It is the home of Lord Northbourne, who is the principal landowner in the district, and who derives his title from the neighbouring village of Northbourne. Here stood King Egbert's palace—sufficient testimony of the antiquity and former importance of the place. Betteshanger House is a beautiful Elizabethan mansion (see fig. 59), standing in a well-wooded park and surrounded by charming pleasure-grounds and gardens. The park is approached by a long carriage-drive, the

occupied by summer bedding plants, all looking in the height of perfection, and reflecting credit on the gardener, Mr. J. Selway.

At the end of the frame-yard, nearer the mansion, an excellent conservatory has been erected recently to take the place of one that formerly stood on the lawn quite near to the house. The new structure was quite filled with such showy greenhouse subjects as *Cinerarias*, *Schizanthus obtusus* (remarkably fine), *S. wisetoniensis*, *Astilbes* (*Spiræas*), *Arums*, *Pelargoniums*, &c, relieved with suitable greenery. Leaving this portion of the garden and entering on to the lawn a beautiful sight presents itself to the view. In front stands the old mansion, that was restored in 1851, bearing on its walls *Roses* and other

Yew hedges, with *Maples*, ornamental *Conifers* and beds of *Roses*, *Azaleas*, flowering trees, such as *Pyrus Malus floribunda*, and a number of other charming subjects.

The beds of *Tulips*, *Narcissi*, and other bulbous plants, with *Pansies*, patches of *Arabis*, *Aubrietias*, *Vinca major*, and a host of other beautiful spring-flowering plants that are succeeded later by the summer occupants of the beds make this a most picturesque spot. Beautiful as is this portion of the grounds, the gardens furnish another equally delightful spot in the shape of an alpine garden. This has been formed on the side of a rising knoll, and the patches of colours of the many occupants are observable from a distance, but it is on a closer inspection that one becomes

FIG. 59.—BETTESHANGER HOUSE, KENT.

banks on both sides of which are planted with *Hypericum calycinum* and *Petasites fragrans*, both of which luxuriate and mingle with wild *Roses* and other native flowers. The land on either side of this roadway is well wooded, and extensive plantations of *Larch*-trees growing in the close canopy system furnish evidence of the importance attached to forestry. This is further evidenced by the timber-yard just inside the park entrance, where the wood grown on the estate is cut up into requisite lengths by suitable machinery. A path to the left of the drive leads to the frame-yard, which is bounded by the potting-sheds, tool-houses, bothies, &c. The smart appearance of these necessary garden adjuncts leads one to expect something good in the general upkeep of the gardens, and in this expectation one is not disappointed. The rows of frames were, at the time of our visit,

beautiful climbers, and made still more picturesque by numbers of terraces, arches, and vases, some of the latter being antique specimens of some old-time artist's skill. It will also be noticed that our illustration shows several large specimen plants of *Myrtles* in square *Oak* tubs.

Looking away from the mansion and across the lawn the park stretches before the view, and of which we present an illustration in fig. 61. When we mention that over thirty acres of pleasure-grounds and gardens are included, irrespective of the park, some idea may be gained of the beauty of the place. The village church (fig. 61) is included in the estate, and a private approach to this edifice leads one through a delightful portion of the grounds. The walk passes by a series of terraces cut in the grass, past innumerable flower-beds, and round the old well shown in fig. 60, and is bordered by pergolas, clipped

charmed with the spot. A path leads through miniature dells, and over mounds where abutting stones and jutting rock-work are draped with masses of *Aubrietias*, *Saxifragas*, *Alyssum*, *Phlox lilacina*, *Lithospermum prostratum*, *Antennaria balearica*, *A. tomentosa*, *Arabis*, and other suitable subjects. A batch of *Tiarella cordifolia* was flowering grandly, as was also *Saxifraga Wallacei*, while the higher back-ground was furnished with taller-growing species, such as *Berberis Darwini*, various forms of *Cytisus præcox*, *C. p. lilacina*, and *C. p. var. lutea* (with lovely, soft, yellow-coloured flowers), *Daphnes*, ornamental *Conifers*, *Azaleas*, &c. A natural pond finds a place at the foot of the rockery, and this is overhung with *Sweet Briar*, *Honeysuckles*, and the *Bitter-Sweet*.

Leaving the rock garden and crossing the lawn past clumps of shrubs, some of which are shown in fig. 61, and beneath the shade of noble *Copper*

Beeches some well-designed scroll flower-beds and Roses in abundance may be observed. A grass drive from the lawn terminates in a tennis court, in the shape of a semi-circle, surrounded by shrubberies and flower borders. Shrubs succeed admirably at Betteshanger; *Arbutus Unedo* does well, as do also Magnolias, Aralias, Lilacs, *Berberis* in numerous species, *Laurus nobilis*, and other equally handsome plants.

The fruit and kitchen-gardens occupy a well-sheltered position, being surrounded by high walls on which are trained fruit-trees, but, like the majority of fruit-trees this season, there is but little fruit. Included in this part of the garden are the glasshouses, of which there is an admirable lean-to range, embracing Peach-houses, viney, plant-houses, &c., and several useful warm pits for propagating, &c. The viney at the time of our visit was about to be replanted with fresh Vines.

Before we concluded our visit we were conducted to a portion of the grounds that was interesting. It has recently been converted into a fruit and vegetable-garden, and is on a slope at a lower level than the surrounding land. A series of channels conducts the sewage from the estate over the land, and feeds the various trees, vegetables, &c., past which it flows. Fresh channels are dug at intervals, so that the ground becomes enriched and watered by this means. We were informed that excellent results were obtained on this land, although we suspect that in time the land may become soured from excess of organic acids.

FIG. 61.—VIEW IN THE GROUNDS AT BETTESHANGER PARK.

LEAVES FROM MY CHINESE NOTE-BOOK.

[SEE SUPPLEMENTARY MAP.]

(Continued from p. 147.)

III.—KIATING-FU.

THIS is a large and prosperous city in the west part of the Province of Szechuan, some 1,800 miles inland from Shanghai. It is prettily situated at the point where the Tung and Min rivers unite, in long. 104° E., lat. 29° 34' N., and is 1,070 feet above the sea-level. It is said to contain 35,000 inhabitants. Commercially it is a very important trade centre. All goods from down river are transhipped here, those for the west being placed on rafts, which ascend the main tributary of the Tung, the Ya river, as far as Yachan-Fu. Transversely, goods from the west are transhipped from the rafts and placed on boats. It is also the centre of a very large silk industry, and holds a monopoly of the white wax trade in this part of China. The city itself is built on a flattish, more or less triangular piece of ground, the Tung forming one side, and the Min the base of the triangle. It is surrounded by low hills, many of which are nicely wooded, chiefly with Pines. Facing the south-east angle of the city, and on the opposite bank of the Min river, are two hills about 350 feet high with red sandstone precipices sheer to the water's edge. The tops and farther sides of these hills are densely clad with trees and shrubs, amongst which nestle several temples and two pagodas. Facing the embouchure of the Tung river, in a recess, is a colossal figure of a seated Buddha fully 350 feet high. The head and lower portion of the legs are the only parts distinctly visible, the body itself being hidden by brushwood (*Eriophorum comosum*), and several grasses cover the crown of the head, and above the eyes and mouth, like eyebrows and moustache respectively, giving a ludicrous appearance to the whole head. The sides of the recess are covered with sculptured designs.

Long ago, Kiating was evidently the centre of an ancient race of cave-dwellers, which the Chinese term Mantzu. (The word "Mantzu" simply means "savage," and is used loosely to designate all the aboriginal inhabitants in these parts.) The rocks hereabouts are of red sandstone, and contain hundreds and thousands of caves. These caves are more or less rectangular chambers, about 6 feet high, varying in length and breadth. Sometimes they are divided into several such chambers. These caves were excavated by no rude hands, who have left behind no other trace of themselves. Many of the caves are in inaccessible parts of the cliffs, while others are now below the level of the river. Whether they were the ordinary dwelling-places of the race or were places of refuge one cannot say. To anyone interested I would refer to the admirable account given by Baber in the Royal Geographical Society's *Journal*, Supplementary Paper, part I., vol. i.

The climate of Kiating is very enervating, being very damp, and with but little sunshine. June, July, and August are very hot months, with much rain. For days together the thermometer does not fall below 90° F., and often stands as high as 105° F. in the shade. September and October are very wet, sunless months. November is the nicest month of the whole year, and one can usually reckon on twenty fine and more or less sunny days. December, January, and February are raw and cold; the thermometer does not fall below the freezing-point, but sleet and white frost are not unknown. In March the temperature fluctuates very much. April and May, showery and warm, leading up to the summer-heat of June. Wheat is harvested in early May. Under such climatic conditions one is prepared for the sub-tropical nature of the flora that obtains. But, the paucity of temperate plants

and the number of shrubs characteristic of Hongkong and Southern China generally are much greater than might be supposed. The wooded hills are mostly clad with *Pinus Massoniana* and *Cunninghamia sinensis* in smaller numbers, those denuded of trees with scrub Oak and dense jungle of *Gleichenia dichotoma*. Others, again, are covered with coarse grass with many bushes of *Melastoma candida*, *Gardenia florida*, many species of *Rose*, *Cratægus Pyracantha*, and clumps of *Arundo madagascariensis*. The bottom-lands are given over to Rice-culture, and the clearings on the side and tops of the hills to sweet Potatoes during the summer season, and to Wheat, Pulse, and "Rape" during the winter months.

Alder (*Alnus nepalensis*), *Pterocarya stenoptera*, and *Hedychium coronarium* clothe the sides of the ditches and streamlets. Pollarded trees of *Fraxinus chinensis*, on which insect white-wax is deposited, are not uncommon around the sides of the Rice-fields. And for feeding silk-worms enormous numbers of Mulberry and trees of *Cudrania triloba* are cultivated. Fine clumps of the Bamboo (*Phyllostachys mitis*) are met with on all sides. On the sandy reaches of the river countless clumps of the lovely grass *Mischanthus sinensis* occur.

Ficus infectoria is very common, usually sheltering a tiny wayside shrine. This is the "Huang Kuo" tree of the Chinese, and one of the commonest trees in Szechuan. Around the temples and courtyards of large houses are many trees of *Cupressus funebris* and *Machilus nan mu*. This last is a handsome evergreen tree, very symmetrical in growth, with straight trunk, altogether one of the handsomest members of the Laurineæ. It and the Cypress are two of the most valuable timber trees in China.

Quercus aliena is a common tree, though seldom allowed to grow to any size. This, together with the Aloe and the Pine, are the principal sources of firewood in this neighbourhood. Most of the scrub Oak belongs to this species. The wood of the Pine is largely used for making matches at Chungking. Another common tree on the hill is *Gordonia anomala*. This is a small Ternstroemiaceous tree, with large white *Camellia*-like flowers. It blooms during the months of October and November, and is then a conspicuous object on the hillside.

Other more or less common trees are:—

Ailanthus glandulosa, *Sapinda Mukorossi*, *Stereulia platanifolia*, *Acanthopanax riciniifolium*, *Broussonetia papyrifera*, *Marlea begoniifolia*, *Paulownia imperialis*, *Melia Azedarach*, *Sapium sebiferum*, *Celtis sinensis*, *Platycarya strobilacea*, *Gleditschia sinensis*, *Cedrela sinensis*, *Pistacia sinensis*, *Rhus hypoleuca*, *R. senialata*, *Ligustrum lucidum*, *Engelhardtia* sp., *Betula alnoides* var. *pyrifolia*, *Castanea sativa*, *Cornus macrophylla*, and around habitations, *Ginkgo biloba*, *Diospyros Kaki*, *Olea fragrans*, *Trachycarpus excelsus*, and the Walnut. A curious evergreen tree (*Symplocos* sp.) is very common, and *Hovenia dulcis* also occurs.

In the autumn the *Rhus hypoleuca* forms lovely patches of colour on the hill-side. Chinese Olives (*Canarium album*) are commonly cultivated, and a few Litchis (*Nephelium Litchi*) are also grown.

Amongst the commonest shrubs here must be placed *Melastoma candida*, *Gardenia florida*, and *Mussaenda pubescens*. The first-named forms a bush 3 to 5 feet high, and is nearly always in flower. In colour the flowers vary from white to deep rose. In the distance it simulates a Rose-bush very closely. *Mussaenda pubescens*, with its thousands of white bracts, is likewise a perpetual bloomer. The *Gardenia* is even more common on the hills here than it is in Hongkong. From the capsule, called "Huang-tzu" (yellow seed), the Chinese extract a yellow paint-dye. They are also used medicinally as a rubefacient. E. H. W.

[With the present issue we give a map prepared by Mrs. Wilson showing the route followed by her husband. ED.]

(To be continued.)

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

THE GERMINATION OF SEEDS.—I am greatly obliged to "H." for his answer to my query on p. 71, where he advances several reasons for the non-germination of seeds, a list of which I gave. The one reason that the seed is old and dead is probably the right one. It is curious that the only packet of seed (*Clivia nobilis*) procured from a firm of repute has germinated, while all the others procured from some one else have practically failed, with the exception of the Aloe, which I was warned might not germinate. A certain measure of blame may be due to myself, but certainly not all. As an instance in point I may quote a recent experience. I obtained a packet of seed of *Eucalyptus citriodora*—none germinated. To test further I procured another packet, still none germinated. Then I got a third packet from the same source, when all germinated. Is it likely that the sower was in fault for the first two failures? Take another case. I sowed some *Mignonette* under similar conditions to some seed I had in my possession, which was obtained a season or two before from one of the world-famous houses. I thought it might be useless, but at any rate I tried it. What was my surprise to find that the seed I thought was old developed into sturdy little plants, whereas the seed supposed to be new was an absolute failure. I suppose it is true of seed as of all else, that the more one pays for it the better it is; and while some prolific seeders, such as *Tropæolums*, can be sold at a minimum figure, the rarer kinds cannot be obtained good except at much cost. The loss of money is not the most disappointing feature in the case, but the loss of time. It would be a great help if the leading seed raisers would draw up a germinating table of seeds of the plants and flowers grown in England. It would not only be a help to amateurs, but a check against the quantity of rubbish on the market to-day. T. R. P.

PENTSTEMONS, ETC., AT JEDBURGH.—

I have on previous occasions noted the excellence of the Pentstemons grown by Mr. Charles Irvine, nurseryman, Jedburgh, who is the founder of a new race of giant Pentstemons, and a visit to his nursery the other day revealed a fine collection of hybrid flowers. Prominent among them was the variety Mrs. Irvine. The flower is of a rosy-pink colour with a purple blotch, and a white throat slightly feathered. This flower is very large, and in it is developed the *Gloxinia* form, so much desired in the Pentstemon. The variety *Siddie* is one of the most perfect flowers in cultivation, being of a bright rose tint, with a pure white throat. Another labelled Sir Henry Irving possesses a bold flower of carmine-rose colour with a bronze blotch in the throat. Another worthy of mention is John Bell, which develops a lovely pencilled throat. The Duchess of Cornwall has a most elegant appearance, being of a light coral colour, with a throat also of white. The above are some of the newest varieties. Provost Hunter has flowers of large size, many of the blooms being 2½ inches across. I have mentioned only a selection, but the entire collection shows an almost unequalled brilliancy of colour, and they are also conspicuous for size and form of bloom, another feature being the closeness and compactness of the spike. Among the seedlings of this year are many showing great promise. On leaving the Pentstemons a lovely collection of *Phloxes* was noticed, most of them being of Mr. Irvine's own raising. I observed many excellent forms which have not yet been placed upon the market. They are all of medium height, and show immense spikes of flowers. The variety *Phyllis* is of a bright magenta colour with a purple eye; and *Beauty*, true to its name, is of a light heliotrope colour, with a white centre. The Duchess of Fife is a charming flower of rosy-lilac striped with white, with a pleasing white eye. Probably one of the finest *Phloxes* in cultivation is the variety Queen Alexandra. It develops flowers of the most perfect form, the individual bloom being large, which is an attractive feature, and it produces a magnificent truss. Many of the older varieties hold

their position, and among these Etna was prominent. Mr. Irvine's nursery has the further distinction of being the home of the white Delphinium. About four years since he perfected this flower, and it has found its way, not only throughout these isles, but largely over the Continent of Europe. Although the Delphiniums were past their best, there was ample evidence that the show had been equal to that of former years. I noticed the white Delphinium growing in considerable quantity. In the production of this new variety Mr. Irvine, who is an expert in the hybridising art, has been particularly successful. The nursery also contains a number of luxuriantly-growing Carnations. *J. W.*

POISONING BY AMANITA PHALLOIDES.—A fatal case of poisoning from eating fungi occurred in King's Lynn recently. A man gathered some specimens, had them cooked, and these were eaten by himself and his family. The fungi were *Amanita phalloides*. About the greater part of a pound was consumed. On August 8 symptoms first appeared in the youngest child, aged two years, about midnight. The mother was shortly after taken ill, and by 3 A.M. all the members of the family were in a serious condition, with the usual symptoms, diarrhoea, vomiting, and excruciating abdominal pains. The youngest child died on the 11th at 8 A.M., and the mother on the 12th at 11 P.M. Another child, aged seven, was removed to the hospital, and is considered to be out of danger, although her case gave considerable anxiety to her medical attendant. The father is convalescent. This is the third case of fungus poisoning followed by fatal results which has occurred in King's Lynn during the past twenty-five years. In all three instances the fungus was *Amanita phalloides*, eaten in mistake for the common Mushroom, and in all three cases I was able to prove its identity by gathering further specimens from the place in which the original fungi were gathered, and submitting them to persons interested. *Charles B. Plouright, M.D., King's Lynn.*

BURNHAM.—You say, "We are not aware of any vestige of monastic buildings now existing." The great dovecot of Dorney Court Farm and some walls formed part of Burnham Abbey when Paul Wentworth held it of the Crown, and, though his brother and colleague in the leadership of the Puritans in Parliament was in the Tower he had the Duke of Norfolk at Burnham in his keeping. Elizabeth could trust the Puritans against the partisans of Mary. I may note that "The Great Trees" were exempted from the Crown grant to Paul Wentworth. *Charles W. Dilke.*

AUTUMN GALES.—The serious damage to shipping by the destructive south-westerly gale which raged over this part of Devon on the 3rd and 4th of this month has been noticed by the Press, but the havoc amongst trees and shrubs, and indeed amongst outdoor plants generally, seems to have been overlooked or not recorded. The force of the gale was, perhaps, more acutely felt in this immediate neighbourhood than in any other district. In my own garden, Fuchsias, scarlet Pelargoniums, Roses, and other decorative plants had their leaves dried and curled as if by the action of severe frost. Runner Beans and Vegetable Marrows suffered in the same way. Even the Laurustinus and the Snowberry (*Symphoricarpus racemosus*) appeared dried up, the latter especially so. Everywhere facing the sea at Exmouth the gale was severely felt. The young trees along the Esplanade, planted at the edge of the path, have the appearance at the present time of being quite dead. Nor are the standard trees alone affected. Against the fronts of the houses facing the sea, shrubs, climbing plants and flowering plants are all spoilt for the remainder of the season. The common Virginian-Creeper and its ally, *Ampelopsis Veitchii*, are withered beyond recovery till another season; the leaves of the latter in almost every case are withered and brown, while the edges of the leaves of the former are curled and dry as if burnt by fire. Even the common Ivy where much exposed presents a similar appearance. Thorn trees and hedges are brown, and the leaves are falling so fast as to

cover the ground in many places. A large piece of the foreshore has recently been reclaimed, levelled, and planted with shrubs and flowering plants, all of which were making good growth, and forming an additional attraction to the place under the name of the Beach Garden. The gale came as a great misfortune for this newly-planted ground, which, being so exposed and so close to the sea, received the full force of the storm, and a thick deposit of sand on some of the beds has been the result, almost burying many of the plants. The spray from the sea probably assisted greatly in the work of destruction. The variegated *Euonymus*, which thrives so well and is planted so extensively all round the Devon coast, appears to have defied the gale better than any other plant, its healthy, glossy leaves being in no way injured. *John R. Jackson, Claremont, Lympstone, Devon.*

—A gale of extraordinary severity for the time of the year swept over this part of the West Riding of Yorks. on Friday night and Saturday, the 18th and 19th inst. It is deplorable to relate that vast quantities of Apples, Pears and Plums were blown off the trees. Vegetables of various kinds suffered greatly. Autumn Giant Cauliflowers, &c., were in many instances completely twisted off. Branches were broken off trees, and one or two had the boles snapped in two near the base. Chrysanthemums also suffered greatly. I may add that Apples and the commoner kinds of Pears promised a better crop than was anticipated. It would be interesting to know if this gale was universal over the United Kingdom. Many flower shows suffered greatly in consequence. *J. Snell, Newall Carr, Olley.*

GRAPE "DIAMANT TRAUBE."—When I first became acquainted with the late Mr. Barron's work on *Vines and Vine Culture*, I visited the old garden at Chiswick and inspected the numerous varieties that were then cultivated there. In the old orchard-house, which was in a dilapidated condition, I noticed a little-known Grape named Diamant Traube. It is described by Dr. Hogg in his *Fruit Manual*, and by Mr. Barron in his *Vines and Vine Culture*. I obtained some "eyes," and grew them into fruiting condition in pots. In September, 1889, I exhibited a basket of Diamant Traube Grapes at a meeting of the Royal Horticultural Society, and it was then awarded a First-class Certificate, which I understood was given by the unanimous vote of the Fruit Committee. I sent some canes of the variety to very distinguished quarters, but no one appears to have been successful with it; and like many other delicious Grapes, it has given place to the showy and almost flavourless varieties that have gained the favour of the public by their noble appearance. I have found this Grape especially valuable for invalids, as it is very thin-skinned, juicy, and delicate in flavour. I was agreeably surprised upon a recent occasion to see finer examples of this Grape than I have ever grown or seen exhibited. I recommended the variety to a gentleman whose residence, White Lodge, occupies a charming position on the borders of Streatham Common, but his gardener was not successful in Grape-growing. Another gardener has been appointed, and during the last year or two he has had the Vine in such excellent condition that it is bearing sixteen bunches of perfectly-finished Grapes of the finest quality, and large in berry and bunch. It is far superior to either Buckland Sweetwater or Foster's Seedling, both in texture and in flavour, and ripens earlier than either of these varieties. The Vine is planted in an inside border, with Gros Colmar, Gros Maroc, Black Hamburg, and Muscat of Alexandria, and all the Vines are fruiting well. In my opinion the Grapes, especially the "Diamant Traube," reflect the greatest credit upon the gardener, Mr. Thomas Fair, who has succeeded in showing what a valuable Grape "Diamant Traube" is when properly grown. *W. Roupell, Streatham Hill, S.W.*

WASPS ATTACKING FRUITS.—On p. 148 Mr. W. H. Clarke says that "bottles of sweetened beer treacle, &c., used as traps for these insects attract them to the trees." After several years' close observation I venture to differ from Mr. Clarke. This season, instead of hanging bottles con-

taining beer and sugar against the walls when the wasps first made their appearance, as has been my practice formerly, I had all the nests that could be found within half a mile radius destroyed. Notwithstanding this they came, and I was once more tempted to use bottles containing beer and sugar as traps. The bottles were emptied on the third day after use, and I found we had captured nearly a peck of wasps and flies. My opinion is that the wasps and flies (and in our case hornets too) find the fruits whether the traps are present or not, and if the traps are there so much the better, as they certainly are a counter-attraction for the wasps, flies, &c. Here we have upwards of 1,500 yards of wall fruits, which would cost much to cover with Hexagon wasp-proof netting as recommended by Mr. Clarke. I should much like to know the general opinion among gardeners on the above subject. *W. J. Snell, Wimpole Hall Gardens, Royston, Cumbs.*

THE ROSARY.

HYBRID TEAS.

MR. GEORGE PAUL, speaking at the Rose Congress held in Paris in May last, in allusion to the origin of hybrid Tea Roses that have been introduced since La France was "sent out," said that even before that Rose was introduced there were already plants in existence that had a similar origin. Mr. Paul himself introduced Cheshunt Hybrid, one of the first hybrid Teas. This was produced accidentally in a house where Prince Camille de Rohan was growing. Just below this plant was a Rose much resembling the Bengal Rose, and the result of the cross between the two flowers was the variety now known as Cheshunt Hybrid.

When the late Mr. Henry Bennett tried some experiments he obtained a fine series of hybrid perpetuals, among them Lady Mary Fitzwilliam. It is so difficult to distinguish between hybrid perpetuals and hybrid Teas that some day both groups will be classed together as under the general category of hybrids.

Mr. Paul expressed the hope that English, French, and American hybridisers would not neglect the fine group of hybrid perpetuals which were so valuable for fertilising hybrid Teas, as it would then be possible to obtain a series of hybrids which would bloom from spring to the end of November, as was already the case with some varieties of the Bengal Roses.

Obituary.

RICHARD BOSTON.—We learn with regret of the decease of this florist, who died at Burley, near Leeds, on the 16th inst., and was interred at Lawnswood Cemetery on the 18th. Deceased was sixty-three years of age. While not in the strict sense of the term a professional horticulturist, his life for many years had been in close touch with gardeners. For over thirty years he owned and personally conducted one of the largest fruiterer's businesses in the North of England, situate in Boar Lane, Leeds. He displayed indefatigable energy in advancing the claims of horticulture as an uplifting influence on the whole population in large towns and cities. As Chairman of the Parks and Open Spaces Committee he had for many years opportunities of carrying out his views in this matter. It is questionable if any other city in England is better supplied with parks and open spaces than is the city of his adoption. Mr. Boston was a native of the village of Kirkby Wiske, near Bedale, and a nephew of Mr. William Boston, nurseryman, of that place, who is, I believe, one of if not the oldest nurseryman in business in Yorkshire. *H. J. C.*

SOCIETIES.

BISHOPS STORTFORD HORTICULTURAL.

AUGUST 16.—The thirty-sixth annual Show of the above Society was held on the above date, by permission of John Barker, Esq., in the grounds of the Grange, and as regards entries and general excellence it eclipsed any previous year's efforts. There was in addition a record gate—over 10,000 persons paying for admission. The weather was favourable. The officials are deserving of much praise for their excellent management.

Open Classes.—There were twenty-one open classes, and these constituted a leading feature of the show. The premier class was that for groups of plants arranged for effect, not necessarily in a half circle, but with taste and for good effect. Placed in the centre of a large tent they formed objects of great attraction during the day. The 1st prize was won by a beautifully-arranged group of flowers and grasses staged by Mr. Harrison, gr. to Col. G. B. ARCHER HOUBLON, Hallingbury Place, Bishops Stortford. J. BARKER, Esq. (gr., Mr. Beech), was a close 2nd; Mr. C. GOLD, Stansted, 3rd.

For smaller groups, Messrs. WILBY, Mrs. TAYLOR, and Mr. W. HOLLAND were the winners.

In the class for foliage plants Mr. GOLD was a good 1st, with Col. A. HOUBLON, 2nd; while for six foliage and for six stove plants Mr. GOLD and Mr. J. BARKER were the winners.

The class for exotic Ferns was well contested, Messrs. GOLD, BARKER, and HARRISON winning in the order named.

Groups of tuberous Begonias are always a feature at this show, and this year they were of the usual high-class standard, the plants, though not large, being of splendid quality. Premier honours were taken by Mr. W. SMITH, who for many years has been a strong supporter of the Society. Mrs. TAYLOR was a good 2nd. The other Begonia classes were all strongly contested. Messrs. HARRISON and HOLLAND were 1st in each of two Gloxinia classes. Mr. BARKER was 1st for single zonal Pelargoniums, and also 1st for Coleus; Messrs. HOLLAND and CALVERT being 2nd and 3rd respectively. Messrs. BARKER and HARRISON led in the class for Fuchsias, while Messrs. JEFFERIES and GOLD had the best table plants. Mr. BARKER staged a splendid group of early Chrysanthemums, there being no other competitor.

Cut Flowers.—These occupied much space, and were generally of good quality. For twenty-four bunches of hardy, bulbous or perennial flowers Messrs. PAUL & SON, Chesnut, were an easy 1st with grand bunches, including some very fine Gladioli. Mr. W. GEE was 2nd; and Mr. H. C. PULHAM, Elsenham, 3rd. In the smaller class for twelve bunches of hardy flowers, Messrs. HARE, BARKER, and FORBES won in the order named. Mr. J. BARKER had the best stove and greenhouse cut flowers; while Messrs. HARRISON, BARKER, and Sir A. WILSON had the best Sweet Peas in a very strong competition. Roses were of indifferent quality. Mrs. TAYLOR and Mr. BARKER had the best stands in the larger class, and Messrs. FORBES and ABBOT in the smaller.

Table Decorations.—A large tent was allotted to ladies' classes, and there was no lack of exhibitors. There was less crowding of material than is often seen, but some tables were furnished with too many colours, and others with material the colour of which would be had by artificial light. The 1st prize display was an excellent one, and was put up by Miss G. P. BELL, Safron Walden, who used Orchids, Lily of the Valley, and Statice. Miss BLYTH, Stanstead, was a close 2nd. Miss M. J. CLAYDON, 3rd. Mrs. G. GOLD had the best decorated fire-place. Mrs. LIVESY and Miss HARWOOD had the best decorated baskets of flowers in the order named; and Miss BLYTH and Miss CLAYDON the best large decorated vases.

Fruit.—Excellent produce was seen in the classes for fruit, and there was a splendid competition. For the best collection of eight dishes some excellent exhibits were staged. Colonel A. HOUBLON was placed 1st, his collection including good Peaches, well-finished Grapes, a meritorious Melon, and Nectarines. Mr. J. BARKER was a close 2nd with fruit not quite ripened, but of good size and finish. The same exhibitors won in the same order for a basket of mixed fruit. Mr. A. JEFFERIES was a good 1st for Black Hamburg Grapes; Colonel A. HOUBLON being 2nd. In the class for any other black Grapes, Colonel A. HOUBLON won with fine examples of Madresfield Court. R. C. GOSLING, 2nd. Mr. J. BARKER was an easy 1st for white Grapes, with bunches of fine colour. 2nd, Colonel A. HOUBLON. The best Melons in two classes from Messrs. PEARSON and JEFFERIES.

Vegetables were both numerous and good. Mr. A. JEFFERIES had the best collection in the larger class, having Peas, Perfection Tomatoes (good), Cauliflowers, Ailsa Craig Onions and Syon House Potatoes. 2nd, Mr. BARKER. For a collection of six varieties, Messrs.

CALVERT and WATTS and Mrs. TAYLOR won in the order named.

Among the non-competitive exhibits Messrs. PAUL, Chesnut, staged hardy flowers; Mr. MORTIMER, Farnham, a very fine lot of Dahlias; Messrs. BURCH, Peterborough, Roses; Messrs. DOBBIE & Co., Rothersay, Potatoes; and Mr. A. PERRY, Winchmore Hill, N., hardy plants.

ENQUIRY.

BATS.—Can any reader inform Churchwarden how to rid a church of bats, with which it is much infested?

ANSWERS TO CORRESPONDENTS.

** EDITOR AND PUBLISHER.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITOR. The two departments, Publishing and Editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPLES: *Anxious.* The following varieties succeeded on clay land where it has been properly drained and the trees planted as near the surface as possible. *Dessert:* Beauty of Bath, Allington Pippin, James Grieve, Worcester Pearmain, Lady Derby, Summer Golden Pippin, Mr. Gladstone. *Culinary:* Bismarck, Bramley's Seedling, Newton Wonder, Grenadier, Royal Jubilee, Golden Noble, Gascoigne's Scarlet.

BEONIAS: *W. W.* There is no disease, but excessive growth, leading to the formation of the outgrowths. Try a little gentle starvation by keeping the plants drier.

CATTELYAS EATEN: *F. H.* The injury is caused by the grub of a fly, *Isosoma orchidearum* (fig. 62), which was first described in our

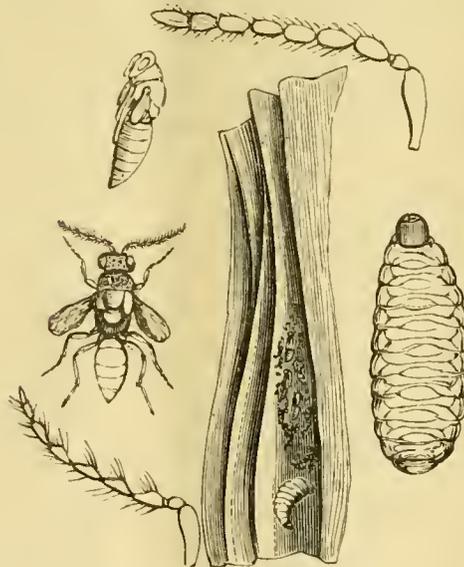

FIG. 62.—ISOSOMA ORCHIDEARUM, THE ORCHID GRUB.

columns, 1869, p. 1230). We fear you can do nothing but destroy the grub when you see evidences of its presence.

CARNATIONS: *J. B.* We do not undertake to name florists' flowers. Send them to some grower.

CARNATIONS: *J. McL.* No fungus or organic disease is present on the growth of *Dianthus Heddewigii*. Some local cause, only to be determined on the spot, has caused the mischief. The portion sent reveals nothing.

CUCUMBER DISEASED: *Roden.* The plant is badly attacked by eel-worm. Turn out the old soil and thoroughly sterilise it before using again. Do not cultivate Cucumbers in the same house for a season.

DAHLIA SOCIETY: *W. H. A.* The Secretary is Mr. Percy Tulloch, Sterndale, Hove, Brighton.

FLOWER SHOWS: *Correspondent.* Tastes and circumstances differ materially from year to year. We should cite the Temple, Shrewsbury, and Wolverhampton shows as in the first rank. This year the Edinburgh show will probably be the most important.

FRUIT AND VEGETABLES: *W. D.* In the absence of any precise stipulation you have no right to do as you propose or to claim compensation. The Figs are affected with a fungus (*Cercospora Boileana*, see *Gardeners' Chronicle*, July 7, 1900, p. 5). Burn the affected leaves. Spray with Bordeaux-mixture next year.

FRUIT FOR NAMING: *Correspondents sending Apples should do so when they are fully developed, in order that all their known characteristics may be present. Pears should be nearly or quite ripe.—R. M. L., Dublin.* Apple Stone's or Loddington Pippin.—*E. R.* Plums, 1, Early Blue; 2, Prince of Wales.

LIMES: *J. W. M.* Apply to Messrs. Draper & Co., Covent Garden Market.

LOAM: *J. C.* What you send seems well adapted for Chrysanthemums, indeed for anything.

NAMES OF PLANTS: *W. J. C.* *Eucomis punctata.*—*H. E. 1,* *Dracocephalum virginianum*; 2, *Helenium pumilum.*—*Case Brothers.* *Centaurea moschata*, a variety sent out, we believe, by one of the German houses.—*A. B. H.* The Lime is catalogued in the *Kew Hand-List* as *Tilia platyphyllos* var. *asplenifolia*. It is the *T. laciniata* of gardens. The *Thuya* is *T. orientalis* var. *pendula*, also called *T. filiformis.*—*Stream, Hampton.* 1, *Lythrum Salicaria*; 2, *Epilobium hirsutum*; 3, *Impatiens noli me tangere*; 4, *Scutellaria galericulata*—*G. P.* *Lycostera formosa.*—*H. C.* *Wicklow.* *Oncidium Schlimii.*—*W. M., Sussex.* 1, *Onychium lucidum*; 2, *Selaginella Wildenovii.*—*P. A. C.* 1, *Vitis* (not recognised); 2, *Colutea arborescens*, *Bladder-Sanna*; 3, *Cupressus pisifera*; 4, *Garrya elliptica*, male flowers; 5, *Pinus excelsa*; 6, *Abies Pinsapo.*—*J. C. W.* Why address the Publisher on such a matter? 1, *Linaria purpurea*; 2, *Hypericum Androsæmum*; 3, *Achillea Ptarmica*; 4, not a Fern, but a *Thalictrum* probably *T. minus*; 5, not a Fern, but a *Thalictrum*, probably *T. flavum*; 6, *Catananche cerulea.*—*Single W.* Yes, a large percentage of *Cytisus Andraeanus*, we believe, comes true from seed. 1, *Thuya plicata*, the *gigantea* or *Lobb* of gardens; 2, *Cephalotaxus pedunculata*; 3, *Juniperus virginiana.*—*An Old Subscriber.* *Cotoneaster frigida*; *Oncidium* next week.—*C. C., Ireland.* *Cattleya Leopoldi* and *Crassavola Perrinii.*—*M. C. T.* *Ceanothus americanus* var. *opaca.*

PLUM-LEAVES: *G. W. B.* Scorching from the sun when the leaves were wet, or possibly the effect of strong gales or lightning.

SEEDLING VIOLA: *J. W. M.* Yes, we think it very pretty, but we are quite unable to say whether there are any better of the same kind. Send to some specialist.

TOMATOS: *B. H.* The discoloured condition is not due to fungi, but to a weakened state of the plant, due perhaps to the absence of sufficient potash in the soil. Try an application of sulphate of potash—a small handful in a pailful of water.

VINES: *A. W.* Your Vines are affected with Browning, a mysterious disease, probably due to a fungus, but concerning which doctors still differ. Cut the affected canes away and burn them. It is very destructive, so that you must exercise every precaution in the matter of strict cleanliness, ventilation, &c.

VIOLAS: *C. A. B.* We find no fungus. The death of the roots and foliage may be due to drought.

SHROPSHIRE HORTICULTURAL.

EXHIBITION AT SHREWSBURY.

AUGUST 23 & 24.

"A Better Show than Ever."

THAT "nothing succeeds like success" has been demonstrated time and again by men and matters of most opposite character, and the Shrewsbury Show will continue to be an event of much importance, partly because it has succeeded so well in the past. But how has it obtained such an influential position in the world of horticulture? Inaugurated in 1875, when at the first exhibition a sum of only £200 was offered in prizes, the subsequent management of the Society by the Committees and Secretaries, Messrs. Adnitt and Naunton, has been so consistently successful that an unusual rate of progress has been maintained almost uninterruptedly to the present day. The annual exhibition is the most popular horticultural event in the provinces, and it is visited by more gardeners from all parts of the country than is any show which is held out of London.

There have been many and varied circumstances that have contributed to this fact, but there are three matters which are most important. In the first place, no one who has been to Shrewsbury has ever had reason to complain of discourtesy, exhibitors, judges, and the representatives of the Press are given every consideration that is possible, and this has created a widespread affection for the Shropshire society.

The Committee has also recognised fully that the one thing needful to obtain a grand competitive show is to offer prizes of substantial value, and higher than are offered elsewhere. But there is also a third contributory cause of success, and this is that the Committee has from time to time introduced new features to the shows that have enormously increased their interest. The last move in this direction was the institution of the Champion Grape Class several years ago, in which a Silver Challenge Cup of the value of 50 guineas is offered, in addition to the liberal money prizes. Since this class was established the best Grapes exhibited in England have been seen at Shrewsbury.

And this leads us to say that we are looking to the ingenuity of the Shropshire Committee to devise some further means of introducing novel effects in the exhibition that will serve to prevent the interest of the general public from waning, as well as that of exhibitors and gardeners. It may be that even in the arrangement of the plants and flowers something in this way could be done. The appearance of the great plant tent, for instance, already becomes somewhat monotonous from repetition, the general effect being much the same one year as another, although it has never been more beautiful than on this occasion, when the decorative plants were certainly better than we have previously seen them. We refer particularly to some of the plants exhibited in pots of not greater diameter than 10 inches.

For the rest there were few, if any, visitors to the show that would not describe it as the best yet held, good though previous ones have been. Fruit continues to be the most interesting part of the Shrewsbury show, and on this occasion it seemed to us of better quality than ever. This was certainly the case in the classes for collections of sixteen dishes and twelve dishes of fruit. Mr. Goodacre, Lord HARRINGTON's gardener, again won the 1st honours in the larger class, and also in the competition for the best table arranged as for dessert. His success year after year, and against the most formidable opponents, is wonderful. Interest was fully maintained in the Champion Grape class, and Mr. Shingler, Lord HASTINGS' gardener, again won the 1st prize, which includes the Silver Cup. This is the third occasion on which Grapes grown by Mr. Shingler have won this Cup, and under ordinary conditions, therefore, it would have become his property; but, in the view of the Society, Lord Hastings is the exhibitor, and the late Lord Hastings died after winning the Cup twice. Consequently the present peer

has only won it once, and has still but one share in its ownership. It may seem rather hard for the gardener, but the employer is rightly regarded as the exhibitor in all cases. Mr. Shingler, however, is entitled to all the honour possible for having won the Cup against all Britain three times, though for two employers.

Vegetables were of exceptional quality, and abundant.

In the cut flower classes the Dahlias were most prominent, and excellent exhibits of them were made. Then in quantity Sweet Peas were perhaps even more numerous.

Amongst the flowering plants, other than those in the large collections, mention may be made of the remarkable tuberous-rooted Begonias from Mr. DAVIS, Pershore, a farmer, who, having cultivated these plants for some years as a hobby, is now regarded as a cultivator of quite exceptional skill.

The weather on the first day was not good. In the morning rain fell heavily and continuously, but afterwards, at 10 o'clock, appearances improved; there was intermittent sunshine with occasional showers, which became more frequent and severe in the afternoon. All the same, with the experience of the drenching rain on the first day at last year's show fresh in our memory, we refrained from grumbling.

The entries exceeded those of last year by several hundreds. The income of the Society last year amounted to £4,554, the gate-money being £2,431.

FRUIT.

TABLE ARRANGED AS FOR DESSERT.

A class of this kind is nowhere better carried out than it is at Shrewsbury.

The conditions of the competition may be summarised as follows:—The tables measured 10 feet by 4 feet 6 inches, and were to be decorated with plants shown in pots not exceeding 5 inches in diameter, cut flowers (excluding Orchids), and cut foliage. Not more than fifteen dishes of fruit could be shown, and they were selected from the following list:—

	Maximum No. of Points for each dish.
2 vars. Apples 6 on each dish ...	7
2 " Apricots 9 " ...	6
2 " Cherries 50 " ...	5
2 " Figs 9 " ...	7
2 " Black Grapes 1 bunch, to dish (Pointed as in Champion Grape class.	7
2 " White Grapes 1 " ...	7
2 " Melons (single fruit not to be cut) ...	8
2 " Nectarines 6 on each dish ...	8
2 " Peaches 6 " ...	8
2 " Pears 6 " ...	7
1 " Plum 9 " ...	6
1 " Strawberry 40 " ...	6

For decoration the maximum number of points was as follows:—

Beauty of flower and foliage ...	8
Harmonious blending of colours ...	10
General arrangement for effect ...	10

The prizes offered were very liberal:—1st £15, 2nd £12, 3rd £8, and 4th £5. This year there were five competitors, and the 1st prize was won by the Earl of HARRINGTON (gr., Mr. J. H. Goodacre), whose exhibit gained 132 points. These were made up as follows:—

	No. of Dishes.	Points.
Apples ...	1	7
Figs ...	1	5
Grapes (White) ...	2	16½
Grapes (Black) ...	2	18
Melons ...	2	15½
Nectarines ...	2	13½
Peaches ...	2	14½
Pears ...	2	12½
Plums ...	1	5½
Beauty of flower and foliage ...		7
Blending of colour ...		8½
General arrangement for effect ...		8½

The maximum number of points was obtained for Ribston Pippin Apple, and one of the Melons. Souvenir du Congrès Pears were splendid, and all of the fruits very good. They included Bellegarde and Royal George Peaches, Transparent Gage Plums, Elruge and Pineapple Nectarines, Dr. Guyot as well as the Souvenir du Congrès Pears, Black

Hamburg, Muscat of Alexandria, and Madresfield Court Grapes, and wonderful Ribson Apples, in addition to Melons and Figs. The flowers used in decoration consisted of Montbretias and Francoas, relieved with trailing growths of Selaginellas. The 2nd prize was obtained by G. FARQUHAR, Esq., Eastnor Castle (gr., Mr. G. Mullins), whose number of points was 126; against 113 points obtained by T. CORRETT, Esq., Impney Hall, Droitwich (gr., Mr. F. Jordan), who was third; and 111½ points awarded to Lord BIDDULPH, Ledbury Park (gr., Mr. J. Dawes), who had the 4th prize.

COLLECTIONS OF FRUIT.

The collections of fruit arranged on one side of the centre tables in the large fruit-tent had a better effect than ever, and were of excellent quality.

Sixteen dishes, distinct. — Notwithstanding the exacting nature of this class there were five competitors. The 1st prize was gained by Lord HARRINGTON, whose exhibit was of extraordinary merit, especially from the point of view of weight, and in some cases finish and colour also. His Grapes were Black Hamburg, of good weight and richly coloured; Muscat of Alexandria, of enormous size in the bunch, but lacking colour and finish; Madresfield Grape (good), and Chasselas Napoleon, of very large size and good quality. He had also excellent, brilliantly coloured Elruge Nectarines, fine Royal George Peaches, large and intensely coloured fruits of Emperor Alexander Apple, Moor Park Apricot, Transparent Gage Plums, Negro Largo Figs, Souvenir du Congrès and Triomphe de Vienne Pears, Morello Cherries (extra good), the Strawberry-Raspberry, and two Melons. A very fine exhibit from T. CORRETT, Esq., obtained the 2nd prize. In this collection the Madresfield Court and Black Hamburg Grapes were very good, Dymond Peaches and Hems Kirk Apricots were excellent, Triomphe de Vienne Pear good, Pineapple Nectarine excellent, &c. 3rd, J. MARTIN WHITE, Esq., Balruddery (gr., Mr. R. Cairns); 4th, G. FARQUHAR, Esq.; and 5th, the Hon. E. L. WOOD, Temple Newsam, Leeds (gr., Mr. R. Dawes).

For decorations in this class T. CORRETT, Esq., won the 1st prize; G. FARQUHAR, Esq., 2nd prize; and Lord HARRINGTON the 3rd prize.

Twelve Dishes, distinct. — Pineapples were excluded from this class. There were three competitors, and the 1st prize was well won by Lord BIDDULPH, Ledbury Park (gr., Mr. Jas. Dawes). He had Black Hamburg, Gros Maroc, and Muscat of Alexandria Grapes, Diamond and Grosse Mignonne Peaches, Lord Napier and Humboldt Nectarines, Souvenir du Congrès Pears, Transparent Gage Plums, Brunswick Figs, Lady Sudeley Apple, and Hero of Lockinge Melon. The 2nd prize was won by Mrs. F. NEED, Great Malvern (gr. Mr. J. Jones); and 3rd by J. DRAKE, Esq., Market Rasen (gr. Mr. S. Bontoff). The prizes for decoration were in this class awarded in the same order as those for the fruit.

Nine Dishes, distinct. — In this competition for the smallest number of dishes, reserved to cultivators in the county of Salop, there were four very pretty and meritorious exhibits. The best collection was one from C. F. K. MAINWARING, Esq., Oteley, Ellesmere (gr. Mr. C. Wilkins); the Rev. T. M. BULKELEY OWEN won the 2nd prize, and Mrs. SWANN, Halston Hall (gr. Mr. C. Roberts), the 3rd prize, but this exhibitor had the 1st prize for the decorations used in the class.

SINGLE DISHES OF FRUIT.

Peaches were, as they always are at Shrewsbury, of the highest quality. There were sixteen exhibits of six fruits each, and the prizes were awarded as follows:—1st, for Bellegarde, as shown by G. F. BATES, Esq., Hereford (gr., Mr. R. Grindrod); 2nd, Royal George, from the Earl of HARRINGTON; and 3rd, Dymond, from J. W. FLEMING, Esq.

Nectarines displayed even more depth of colour than the Peaches. The 1st prize was awarded to six splendid fruits of Lord Napier, from Lord HARRINGTON; the 2nd prize to Humboldt, shown by the Hon. E. L. WOOD; and the 3rd to the variety Spencer, from J. DRAKES, Esq.; Downton, Rivers' Early and Pit-maston Orange were also exhibited in this class.

Apricots.—There were eleven dishes of Apricots, the fruits in some of them being remarkable for their large size and good colour.

Melons.—More variety is usually seen in the classes for Melons than in those for most other fruits. In the class for the best green-fleshed fruits, the fruits varied

very much in size especially. The 1st prize was awarded to an exceedingly small fruit of the variety Earl's Favourite, which had evidently been selected for its superior flavour. The 2nd and 3rd prizes also went to small fruits, thus showing that in Melons at least judges do not always give the 1st place to mere size. In a competition for the best scarlet-fleshed variety there were as many as twenty fruits shown, and the prizes were awarded as follows:—1st, R. H. KENYON, Esq., Pradoc, Oswestry; 2nd, W. J. LEGG, Esq., Madeley Market; and 3rd, Captain T. A. M. DICKIN, Loppington House, Shrewsbury. In the class for white-fleshed Melons there were fifteen fruits shown, the Hon. E. L. WOOD winning the 1st prize.

Plums.—The best Gage Plums were beautiful examples of Transparent Gage, and were shown by the Earl of HARRINGTON, and the best yellow Plums were Golden Drop, shown by the same exhibitor. Of purple or red-fruited Plums there were Prince Englebert, shown by the Rev. T. M. BULKELEY OWEN: the variety Kirke's, from the Earl of HARRINGTON, being 2nd.

LOCAL CLASSES.

There were classes for six dishes of fruit distinct, also for single dishes of Apples and Pears, shown by exhibitors in the county, and the exhibits seemed to indicate that the holding of the shows at Shrewsbury has an effect in encouraging good cultivation in the neighbourhood, as well as in distant parts. The 1st prize in the class for six dishes of fruit was won by Mrs. F. ALDERSON, Samson Hill.

Cherries were very fine, and of the nine dishes staged the best were of the variety Bigarreau Napoleon, shown by G. FARQUHAR, Esq.

CHAMPION GRAPE CLASS.

If there is one class at Shrewsbury that excites more general interest than any other it is this one, which was established in 1902. Each exhibit consists of twelve bunches of Grapes, in four or more distinct varieties, but not including more than four bunches of any one variety. In our opinion the Society has done well to make the maximum numbers of points obtainable for the different varieties correspond approximately to the degree of merit in the particular variety. Thus the maximum for Muscat of Alexandria was 11 points, for all other varieties of Muscat (black or white), and for Black Hamburg 10 points, and all other varieties of Grapes 9 points. The bunches were staged on boards in two tiers 2 feet 3 inches in width. The judges were instructed to regard superior cultivation and finish as of the greatest importance. The 1st prize consisted of a Silver Cup value 50 guineas, and £20 in cash; 2nd prize £16, 3rd £12, 4th £7 10s., 5th £5, and 6th £4. The Silver Cup has to be won three times by the same exhibitor before it becomes his property. In 1902 the winner was the late Lord HASTINGS (gr. Mr. W. Shingler); in 1903 Lord HARRINGTON (gr. Mr. J. H. Goodacre), and in 1904 Lord HASTINGS won it for the second time. When therefore the 1st prize was awarded Lord HASTINGS on Wednesday last, it was surmised by some that the Cup would become his property. This was not the case, however, because the present Lord HASTINGS has won it but once, and his late father won it twice. The Grapes shown by Lord HASTINGS on this occasion were as follows, with the number of points awarded to each bunch:—

FIRST PRIZE EXHIBIT.

Variety.	Maximum No. of Points.	Points awarded.
1. Madresfield Court ...	10	9½
2. Muscat of Alexandria ...	11	9½
3. Mrs. Pince ...	10	9½
4. " ...	10	9½
5. Muscat of Alexandria ...	11	9½
6. Madresfield Court ...	10	9½
7. Gros Maroc ...	9	8½
8. Alnwick Seedling ...	9	9
9. Muscat of Alexandria ...	11	10
10. " ...	11	9½
11. Madresfield Court ...	10	9½
12. Alnwick Seedling ...	9	9
		112½

It will be seen that the maximum number of points was awarded to each of the bunches of Alnwick Seedling, but to no other variety. The bunches, however, of Mrs. Pince, Madresfield Court and Muscat of Alexandria (excepting one bunch) were very heavy bunches,

and were almost perfect in colour and finish. The 2nd prize was won by the Earl of HARRINGTON, who showed the following varieties:—

SECOND PRIZE EXHIBIT.

Variety.	Maximum No. of Points.	Points Awarded.
1. Muscat of Alexandria ...	11	9
2. Madresfield Court ...	10	9½
3. Muscat of Alexandria ...	11	9
4. Black Hamburg ...	10	9
5. Muscat of Alexandria ...	11	9
6. Madresfield Court ...	10	9½
7. Madresfield Court ...	10	9½
8. Muscat Hamburg ...	10	8
9. Black Hamburg ...	10	9
10. Muscat of Alexandria ...	11	9½
11. Black Hamburg ...	10	9
12. Madresfield Court ...	10	9½
		109

In no case was the maximum number of points awarded to a bunch in this exhibit, yet the general quality was so high that the total number gained was only 3½ fewer than in the 1st prize exhibit. The 3rd prize was won by J. M. WHITE, Esq., Balruddery (gr. Mr. R. Cairns), who was awarded 95 points. 4th, G. FARQUHAR, Esq., Eastnor Castle (gr. Mr. G. Mullins), who obtained 90 points. 5th, the Hon. E. L. WOOD, Temple Newsam, Leeds (gr. Mr. R. Dawes), with 76 points.

Each collection was decorated with flowers or foliage plants (in pots not exceeding 5 inches in diameter), also cut flowers or foliage in glass or otherwise. The decorations were not considered when awarding the prizes for Grapes, but three additional prizes were given for the best decorated exhibits, and the 1st prize was awarded to J. DRAKES, Esq., Market Rasen (gr. Mr. S. Bontoff).

SPECIAL VARIETIES OF GRAPES.

Four Bunches, two Black and two White.—In this, the largest class in the ordinary Grape classes, there were eight competitors, and an excellent exhibit of Madresfield Court and Muscat of Alexandria, shown by W. MARSH, Esq., Bath (gr. Mr. W. Taylor), was awarded the 1st prize. The bunches of Muscat of Alexandria were of average form and colour, but were remarkable for the large-sized berries and considerable weight. J. WILLIS FLEMING, Esq., Chilworth Manor, Hants (gr. Mr. W. Mitchell), was 2nd; and Lord HARLEIGH, Brogyntyn (gr. Mr. T. Lambert), 3rd, with the same varieties.

Black Hamburg.—Of four exhibits in a class for two bunches, the best was from J. WILLIS FLEMING, Esq., who had heavy, well-shouldered bunches and highly-coloured berries, which would have been even better had the thinning been more severe. 2nd, C. F. K. MAINWARING, Esq., Oteley, Ellesmere (gr. Mr. C. Wilkins); and 3rd, Mr. W. A. COATES, Glan Conway. In a class for a single bunch of the same variety Mr. W. A. COATES won the 1st prize somewhat easily from seven other competitors, and mainly owing to the good size and colour of the berries.

Black Grapes (Muscat Varieties). There were few exhibits in this class. The variety Muscat Hamburg, as shown by the Rev. F. M. BULKELEY OWEN, Tedsmore Hall, West Felton, was placed 1st; Madresfield Court and Mrs. Pince, from J. BRINTON, Esq., Stourport (gr. Mr. W. H. Wilson), 2nd; and rather badly-coloured Muscat Hamburg, from E. A. YOUNG, Esq., Tan-y-Bryn (gr. Mr. A. Ruddock), 3rd.

Madresfield Court.—This was a good class, and excellent bunches from J. WILLIS FLEMING, Esq., were found for the 1st prize. They were not exactly a good pair, as one bunch lacked the handsome shoulders seen in the other, but both were of considerable weight, and in colour and size of berry left little to be desired. J. BRINTON, Esq., was 2nd; and the Earl of HARRINGTON, 3rd.

Black Alicante.—For this variety there were five competitors, but the 1st prize exhibit, from W. MARSH, Esq., were much the best, being very heavy and of intense colour. They would have been better, however, had the berries been of larger size. 2nd, Lord TREVON, Brynkinalt (gr. Mr. W. Davies); and 3rd, Col. C. FRANCE-HAYHURST, Middlewich (gr. Mr. A. H. Hall).

Any other Black Grape.—The variety Gros Maroc as shown by W. MARSH, Esq., was awarded the 1st prize, the bunches being very fine in weight, size of berry, and

in colour. Lord HASTINGS, Melton Constable (gr. Mr. Shingler), won the 2nd prize; and C. F. K. MAINWARING the 3rd, with the same variety. Alnwick Seedling appeared to be the only other variety exhibited in this class.

White Muscats.—The exhibits of Muscats of Alexandria were not specially remarkable. Of the six bunches shown, the best was from Col. C. H. FRANCE-HAYHURST; and the Earl of HARRINGTON had the best for 2nd prize. A very highly-coloured bunch from T. CORBET, Esq., Impney Hall, Droitwich (gr. Mr. F. Jordan), was too small to obtain the prizes, but the berries were the most tempting of any in the class. In the larger class for two bunches there were nine exhibits, and the quality was generally better. The 1st prize was won by W. MARSH, Esq., who had one short, thick bunch and one very long bunch, a had pair, but both heavy and having very large berries and satisfactory in colour. 2nd, Col. C. H. FRANCE-HAYHURST; and 3rd, Earl of HARRINGTON. In the 2nd and 3rd prize exhibits the berries were in a riper condition than were those in Mr. MARSH's exhibit.

White Grapes, any other variety.—A really excellent pair of bunches of Buckland Sweetwater obtained the 1st prize in this class. They were shown by H. A. ATTENBOROUGH, Esq., Daventry (gr. Mr. A. Child), and the berries were of wonderful size, while the peculiar transparent appearance so characteristic of the variety was splendidly developed. The same variety but in a much inferior condition, from Capt. HETWOOD-LONSDALE, Shavington Hall (gr. Mr. J. Mills) was placed 2nd; and Chasselas Napoleon, from J. CORBET, Esq., won the 3rd prize. There were only two bunches of Foster's Seedling shown, and they were of poor quality in comparison with the Buckland Sweetwater.

LOCAL CLASSES.

In the Grape classes, confined to cultivators in the county of Salop, very fine bunches of Madresfield Court won 1st prize for the Rev. T. M. BULKELEY OWEN, Tedsmore Hall; Lord HARLEIGH had a 1st prize for Alnwick Seedling, showing capitally finished bunches; Capt. IFFYWOOD-LONSDALE won the 1st prize for Muscat of Alexandria, and for Foster's Seedling in the class for any other white Grapes.

GROUPS OF PLANTS.

The groups of ornamental plants arranged for effect at provincial shows are of a type now well known to readers of this journal. Those at Shrewsbury this year, though possessing no new feature of importance, were quite entitled to be described as works of art. They were splendid examples of studied arrangement of plants varying equally in their form and colours. The first class was one for a group of miscellaneous plants in and out of bloom arranged in a space of 300 square feet. Messrs. J. CYPHER & SONS, Cheltenham, were awarded the 1st prize for an exhibit consisting of plants arranged in mounds and glades, but in which arches of cork, which have been somewhat overdone in these groups, were omitted. Some of the most effective flowering plants used were *Oncidiums* and other *Orchids*, *Kalanchoe*, *Lilium speciosum*, and *Pan-cratiums*. 2nd, G. H. KENDRICK, Esq., Edgbaston, Birmingham; and 3rd, Mr. J. VAUSE, Leamington.

In the following class the group was one of ornamental foliage plants, Palms, Ferns, &c., arranged on a space of 300 square feet. Flowers and plants in flower were excluded. The winners of the 1st prize were the LEAMINGTON NURSERYMEN & FLORISTS CO., Ltd., Leamington. The feature of this group was the brightly-coloured *Codiaeums*, and a very handsome plant of the variegated *Dracena* "Victoria." Messrs. J. CYPHER & CO., who were placed 2nd in this class, had a group of splendid plants, but one in which the colours were rich but lacked brightness. A few golden-coloured *Codiaeums* would have served to lighten the group, and it would then, in our opinion, have been equal to that which gained the 1st prize. 3rd, the Earl of CARNARVON (gr. Mr. T. Read). Extra prizes were also awarded to Messrs. W. SANDFORD & Co., Birmingham; and to G. H. KENDRICK, Esq., Edgbaston.

SPECIMEN PLANTS.

Fifteen Stove and Greenhouse Plants.—Messrs. JAS. CYPHER & SONS, Cheltenham, won the 1st prize in this class, with specimens that appeared of very large size even in the spacious and lofty marquee in which these exhibits are staged at Shrewsbury. The species were *Ixora Fraseri*, *Bougainvillea Cypheri*, *Statiche profusa*, *Stephanotis floribunda*, *Erica Everiana*, *Croton* (*Codiaeum*) *Victoria*, *Allamanda nobilis* (2), *Chironia*

ixifera, *Statice intermedia*, *Bougainvillea glabra* (3), *Erica oblata purpurea*, and *Kentia Fosteriana* (2). The 2nd prize in this class was won by Mr. W. VAUSE, who showed good specimens of the species usually exhibited in this class.

For Six Stove and Greenhouse Plants, not fewer than Four in Bloom.—1st, Messrs. J. CYPHER & SONS, Cheltenham, with wonderful examples of *Bougainvillea Cypheri*, *Allamanda nobilis*, *Erica Austriana*, *E. Eweriana*, *Isora Duffii*, and *Statice profusa*. 2nd, Mr. W. VAUSE, Leamington. 3rd, T. SUTTON TIMMIS, Esq., Allerton, Liverpool (gr., Mr. B. Cromwell).

With Six Foliage or Variegated Plants, T. SUTTON TIMMIS, Esq. (gr., Mr. B. Cromwell), was an easy 1st with three exceedingly well-grown *Codiaeums* and three Palms. 2nd, Messrs. J. CYPHER & SONS. 3rd, Mr. W. VAUSE.

Thirty Stove and Greenhouse Plants—The 1st prize exhibit in this class was one of the prettiest features of this nature we have observed for some time past; all the plants were so well grown and so bright in effect that they were unusually attractive. The plants could not be shown in pots of greater diameter than 10 inches, and it was very surprising that such specimens as were shown by T. SUTTON TIMMIS, Esq., Allerton, Liverpool (gr., Mr. B. Cromwell), could be produced in such pots. A plant of *Codiaeum (Croton) Chelsoni*, 9 feet high and 5 feet through, was probably the best *Codiaeum* ever exhibited in a 10-inch pot. The plant retained its leaves right down to the base, and was highly coloured. We can only mention a few of the most interesting species in this group—*Isora Duffii*, *gloriosa*, *superba*, *Chironia ixifera*, *Clerodendron fallax*, *Alocasia Sanderiana*, &c. Messrs. J. CYPHER & SONS were 2nd.

Some good *Coleus* were shown as pyramids, ranging from 4 to 6 feet in height, the best being a collection of four plants from Col. W. GORDON PATCHETT, Greenfields, Shrewsbury (gr., Mr. J. Swain).

Zonal *Pelargoniums* were not specially good generally, but some good plants were shown by Mr. R. TAYLOR, Abbey Foregate, Shrewsbury (gr., Mr. H. Cliff).

Exotic Ferns were best shown by T. SUTTON TIMMIS, Esq., Allerton, who had very large and good specimens of *Nephrolepis davallioides furcans*, *Davallia fijiensis plumosa*, *Goniophlebium subauriculatum*, and *Microlepia hirta cristata*.

Tuberous Begonias.—A group of tuberous *Begonias* covering a space of 15 feet by 4 feet. In this class Mr. F. DAVIS, Woolashill, Pershore, was 1st, with a collection of well-grown plants bearing unusually large flowers of perfect shape and substance. 2nd, Messrs. BLACKMORE & LANGDON, Twerton Hill Nurseries, Bath.

There were also classes for plants grown by cultivators residing in the county, and these included one for a group of miscellaneous plants arranged on a semi-circular space of 100 square feet. In this class the winner of the 1st prize was Mrs. SWANN, Halston Hall, Oswestry (gr., Mr. C. Roberts).

CUT FLOWERS

The 1st prize for a bride's bouquet was awarded to Mr. GARNER, Altrincham, whose flowers consisted principally of *Odontoglossums*. 2nd, Mr. W. TRESEDER, Cardiff.

The prettiest bouquet for the hand also came from Mr. GARNER. 2nd, Mr. W. TRESEDER. 3rd, Messrs. FELTON & SONS, Hanover Square, London.

In a class similar to the last-named, but in which Orchids were not admissible, Messrs. FELTON took premier position with pink *Carnations*. 2nd, Messrs. JENKINSON & SONS. 3rd, Mr. W. TRESEDER.

Messrs. FELTON were again 1st for a feather-weight bouquet. 2nd, O. ROBINSON, Esq., Alderly Edge (gr., Mr. J. Nixon).

Messrs. FELTON were awarded 1st prize for a shower bouquet composed of *Cactus Dahlias*, Mr. GARNER being 2nd, and Mr. W. TRESEDER 3rd.

1st and 2nd prizes went respectively to Messrs. FELTON & SON and Mr. W. TRESEDER for a floral harp. The 1st prize harp consisted principally of *Cypripediums*, *Cattleyas*, &c., over a groundwork of white *Asters*.

O. ROBINSON, Esq., Alderly Edge (gr. Mr. J. Nixon), secured the 1st position in the class for a floral wreath, Messrs. FELTON & SON coming 2nd. The 1st prize wreath was composed largely of *Stephanotis floribunda* and light-coloured *Cattleyas*. Messrs. FELTON, who were placed 2nd, used *Cattleyas* of rather dull colours and heavy.

A class for a stand of cut flowers for table decoration brought eleven exhibitors, and after a very keen struggle O. ROBINSON, Esq. (gr. Mr. J. Nixon), was placed 1st. The flowers employed were *Lilies of the Valley*, *Gloriosa superba*, and *Pancreatiums*, arranged on a rustic stand. 2nd, Miss M. MORGAN, St. Mary Street, Shrewsbury.

Messrs. FELTON took the lead for six button-hole bouquets and sprays for ladies. 2nd, O. ROBINSON, Esq. (gr., Mr. J. Nixon). 3rd, Messrs. M. JENKINSON & SON.

In a class for a basket of cut flowers for the drawing-room, five exhibits were placed before the judges, who gave the premier award to Messrs. FELTON with a delightful arrangement of *Oncidiums* and *Cattleyas*. 2nd, O. ROBINSON, Esq. (gr., Mr. J. Nixon). 3rd, The LEAMINGTON NURSERIES, Ltd., Bedford Street, Leamington.

Hand-basket of flowers (Orchids excluded). Messrs. FELTON again beat all competitors. 2nd, O. ROBINSON, Esq. (gr., Mr. J. Nixon).

The class for an arrangement of cut flowers suitable for a dinner-table covering a space of 4 feet by 4 feet was strongly contested, and great taste was displayed in the arrangement of the various exhibits. The 1st prize was eventually awarded to Miss M. MORGAN, Shrewsbury, who relied upon pink *Carnations* and *Lily-of-the-Valley* set in rustic stands. 2nd, Miss MARY ALLEN, Wrockwardine Wood. 3rd, Miss M. RUSSELL, Albrighton.

In a class devoted to Sweet Peas for dinner-table decoration, Mrs. NIXON, Alderly Edge, won the 1st prize, and Miss M. MORGAN, Shrewsbury, the 2nd prize.

Liberal prizes were offered by Mr. Robert Sydenham, Birmingham, for Sweet Peas to be shown on rustic table-stands. 1st, E. DEAKIN, Esq., Hay Hill. 2nd, W. H. BANKS, Esq., Kington.

Collection of perennials (Roses excluded). After a very close contest, Messrs. HARNNESS & SON, of Bedale, were placed 1st with a magnificent collection comprising bold bunches of large-flowered *Gladioli*, *Phloxes*, *Liliums*, *Veronicas*, *Campanulas*, &c. 2nd, Mr. M. PRICHARD, Christchurch, Hants. Here were to be seen excellent examples of *Gladiolus princeps*, *Coreopsis lanceolata major*, *Montbretia George Davison*, *Kniphofias*, *Campanula carpatia* "White Star," illustrated in our columns last week, but which appears to be very closely allied to a variety named Robert Parker, which has been in cultivation for several years. 3rd, Messrs. G. GIBSON & SON, Bedale.

Collection of *Cactus* or *Decorative Dahlias*.—1st, Messrs. KEYNES, WILLIAMS & CO., Salisbury, with an admirable arrangement of brightly-coloured *Cactus* varieties. 2nd, Mr. W. TRESEDER. 3rd, Messrs. W. B. ROWE & SON, Worcester.

In the class for mixed *Dahlias*, Messrs. M. CAMPBELL & SONS, High Blantyre, N.B., were 1st with clean, well-developed flowers representative of most of the various types. 2nd, Mr. W. TRESEDER. 3rd, Mr. M. V. SEALE.

Carnations as cut flowers were shown grandly, and in a class for a display arranged on a table space of 6 feet by 4 feet Mr. A. F. DUTTON, Iver, Bucks, won the 1st prize for a very fine lot of flowers in an exhibit similar to others that he has shown in London and elsewhere. The 2nd prize was awarded to Mr. W. A. WATTS, nurseryman, St. Asaph.

In a class from which members of the trade were excluded, a 1st prize was won by W. B. M. VERNON, Esq., Welch Frankton, for a display arranged on a table space of 4 feet by 4 feet.

Classes for Sweet Peas included some in which prizes were offered by Mr. Robert Sydenham, Birmingham; and Messrs. Jones & Son, Shrewsbury. Among the winners of 1st prizes in these classes were J. GIBSON, Esq., Duns, N.B.; and Mr. A. MALCOLM, Duns, N.B.

HONORARY EXHIBITS.

Messrs. DOBBIE & CO., Rothesay, Scotland, set up a very bright exhibit of *Cactus*, *Show*, and *Fancy Dahlias*, together with sixty varieties of *Pansies* on show-boards, sixty sprays of *Violas*, and sixty-six varieties of *Potatoes*.

Messrs. WALLACE & CO., Kilnfield Gardens, Colchester, had an excellent display of hardy plants, amongst which were excellent examples of *Montbretias* containing several very fine seedlings; also *Liliums*, *Phloxes*, hybrid *Tritomas*, *Senecio pulcher*, and choice *Nymphæas*.

Mr. ALBERT MYERS, Sutton Lane Nurseries, Shrewsbury, occupied about 150 square feet of table with a bright display of single and double zonal *Pelargoniums*, comprising plants in pots and cut flowers in

great variety, the whole being tastefully arranged with *Gypsophila* and *Eulalias*.

From Messrs. DICKSONS, Chester, came a collection of well-grown and highly-coloured *Codiaeums* and *Dracænas*. The same firm also arranged a most effective bank of hardy flowers, amongst which were meritorious examples of *Gladioli Jane Dieulafoy* and *Bondoin*, *Phloxes*, *Rudbeckias*, *Delphiniums*, and a grand centre-piece of *Crinum intermedium*.

One of the most interesting and effective arrangements of hardy flowers and *Dahlias* came from Messrs. BAKERS, Codsall, Wolverhampton. The hardy flowers included *Chrysanthemum maximum King Edward*, *Heuchera sanguinea grandiflora*, *Phloxes*, and *Carnations*. *Pompon*, *Show*, *Fancy* and *Cactus Dahlias* were represented by the leading varieties for garden decoration and exhibition purposes. Flowers of double and single zonal *Pelargoniums* were also included in this remarkably fine exhibit.

THE KING'S ACRE NURSERIES, Ltd., Hereford, staged a nice collection of hardy gathered fruit, also pot-trees of *Apples*, *Pears*, *Plums*, and *Figs*, laden with fruit. *Grapes* were represented by *Black Hamburg*, *Foster's Seedling*, and *Muscat of Alexandria*, bearing good sized bunches of nicely coloured berries.

Messrs. ISAAC HOUSE & SON, Coombe Nurseries, Westbury-on-Trym, Bristol, contributed an extensive collection of *Phloxes*, but unfortunately at the time our notes were taken the varieties were unnamed. The undermentioned varieties stood out prominently, *Coquelicot*, *Eugène Dauzanvilliers*, *Sylphide*, *Iris*, and *Walter Wright*, a deep purple flower similar to *Sesotris*.

By far the handsomest collections of *Phloxes* at Shrewsbury this year came from Messrs. GUNN & SONS, of Olton, Birmingham. Each variety was represented by an unusually large bunch of about thirty spikes. The best varieties were *Iris* (blue), *Eugène Danzanvilliers* (lilac), *Sylphide* (white), *Sheriff Ivory* (salmon, crimson centre), *Coquelicot* (very bright), *Adonis* (delicate salmon), *Henri Murger* (white, with a crimson centre).

VEGETABLES.

On no previous occasion here has there been such a remarkable competition in these classes, or such superb quality in the best collections. Not only were many of the leading growers (including Messrs. Beckett, Pope, Horspool, Ashton, Bastin, Leith and others) competing, but many quite new competitors were also there, a fact of great interest in relation to vegetable culture, as it is evident the old champions are not frightening the new-comers out of the field.

Messrs. Sutton and Sons' Prizes.—The very liberal prizes offered by this eminent firm brought sixteen competitors, the winner being Mr. W. L. Bastin, gr. to Sir A. HENDERSON, M.P., Faringdon, who worthily took the 1st place with very high-class products. His collection included fine *Celery*, *Leeks*, *Onions*, *Peas*, *Runner Beans*, *Potatoes*, *Tomatoes*, and *Cauliflowers*. Mr. H. FOLKES, gr. to J. KERR, Esq., Hemel Hempstead, was a very close 2nd. Mr. J. Dymock, gr. to G. D. FABER, Esq., Wallingford, was 3rd; and Mr. J. HUDSON, Leicester, 4th. There were in addition two other awards.

Messrs. Jas. Carter & Co's Prizes.—Very liberal prizes were also offered by this well-known London firm. Mr. E. BECKETT, gr. to Lord ALDENHAM, Elstree, was 1st with produce of his usual superb quality, having very fine *Tomatoes*, *Onions*, *Runner Beans*, *Peas*, *Cauliflowers*, *Potatoes* and other products. Mr. B. ASHTON, gr. to the Earl of LATHOM, Ormskirk, Lancashire, champion competitor, was a close 2nd; and A. DEAKIN, Esq., Haymills, was 3rd. There were three other prizes awarded in these classes.

Messrs. Webb & Sons' Prizes.—For the prizes offered by this well-known firm for a collection of vegetables, Mr. B. ASHTON was well 1st, having superb *Tomatoes*, *Potatoes*, *Runner Beans*, *Red Celery*, *Leeks*, *Cauliflowers* and other kinds. Mr. BASTIN followed closely, taking the 2nd place; and Mr. H. FOLKES was 3rd. There were other awards also.

In the class for twelve dishes in a collection, prizes offered by the Society, Mr. E. BECKETT was again 1st with splendid exhibits. Specially good were *Ailsa Craig Onions*, *New Telephone Peas*, *Potatoes*, *Tomatoes*, *Carrots*, *Runner Beans*, *Parsnips*, *Leeks*, *Celery*, and *Cauliflowers*. Mr. J. HUDSON, Leicester, was 2nd, having a smaller exhibit, but of good quality. Mr. F. J. BARRETT, Overton-on-Sea, 3rd.

Messrs. R. Smith & Son's Prizes for nine kinds of vegetables brought that famous Welsh grower, Mr.

R. A. HORSPOOL, Ruabon, to the front with very high-class exhibits, comprising superb Peas, Tomatos, Turnips, Onions, Leeks, Runner Beans, and Celery. Mr. B. ASHTON was 2nd; and Mr. E. Jones, gr. to the Misses HOWELL, Berrier, 3rd.

Mr. E. Murrell's Prizes.—In the class for these prizes R. C. TOWNSEND, Esq., Chalfont Park, Bucks, was 1st with excellent samples. Mr. T. H. PUGH, Newtown, was 2nd.

Mr. R. Sydenham's Classes.—This well-known Birmingham seedsman offered prizes in many classes, which resulted in splendid competition. In a class for a collection of eight kinds, Mr. W. POPE, gr. to the Earl of CARNARVON, Highclere Castle, Newbury, was a worthy 1st, having capital Onions, Potatos, Carrots, Runner Beans, Celery, Cauliflowers, Peas, &c. Mr. R. A. HORSPOOL came 2nd; and Mr. Leith, gr. to Col. R. MIDDLETON, was 3rd.

The following took the 1st prizes in some of Mr. Sydenham's other classes:—For three dishes of Potatos, Mr. W. POPE won, having Sir J. Llewellyn, The Factor, and Windsor Castle. For Leeks, Mr. J. F. BARRETT was 1st; for Celery, Mr. W. POPE, with Bibby's Defiance; for Turnips, Mr. R. A. HORSPOOL; for Tomatos, Mr. J. READ, Bresty; for Onions and Parsnips, Mr. BARRETT; for Carrots, Mr. POPE; for Califlowers, Mr. HORSPOOL; for dishes of Runner and Dwarf Beans, Mr. LEITH; for Peas, three dishes, Mr. HORSPOOL, who had The Gladstone, Autocrat, and Captain Cuttle.

Liberal point prizes were also offered by Mr. Sydenham, in six diverse amounts. Mr. HORSPOOL came 1st with 59 points; Mr. POPE next with 49; and Mr. LEITH 3rd with 42 points.

The Society's Single Dish Classes.—In most of these classes, some eighteen in number, competition was indeed remarkable, and the quality of the exhibits was exceptionally fine. Mr. W. POPE had the best Carrots; Mr. F. Clark, gr. to MARK FIRTH, Esq., Leicester, the best Parsnips; Mr. G. GUISE, Hadnall, the best Celery; the Rev. G. M. FURLEY, Sockleton, the best Cauliflowers; Mr. C. DEAKIN, the best Runner Beans, having a superb sample; Mr. W. POPE had the best Dwarf Beans; Captain DICKSON, of Wem, the finest Peas; Mr. BECKETT showed superb Cucumbers of the variety Ideal; Mr. B. ASHTON staged the best single dish of Potatos, having the variety Duke of York; and Mr. W. POPE the best three dishes of Potatos, having King Edward VII., Factor, and Windsor Castle.

There was, as usual, an immense number of exhibits in the cottager's tent, and wonderfully-fine competition resulted.

Of non-competing exhibits the most noticeable in vegetables was the collection of sixty dishes of handsome Potatos, set up by Messrs. DOBBIE & Co., and grown on their Seed Farm, Mark's Tey, Essex.

MEDALS AWARDED TO HONORARY EXHIBITS.

LARGE GOLD MEDALS

were awarded to Gunn & Sons, Olton, Birmingham; W. Cuthsall & Son, Highgate; H. Eckford, Wem, Salop; Hobbies, Ltd., Dereham; Dobbie & Co., Rothesay; Bakers, Old Hall Nurseries, Codsall, Wolverhampton; Albert Meyers, Shrewsbury; King's Acre Nurseries, Ltd., Hereford; E. Murrell, Shrewsbury.

SMALL GOLD MEDALS

were awarded to Robt. Bolton, Warton, Carnforth; Jones & Son, Shrewsbury; R. Wallace & Co., Colchester; Dicksons, Ltd., Chester; Pritchard & Sons, Shrewsbury.

SILVER-GILT MEDALS

were awarded to Thos. S. Ware, Ltd., Feltham; Hewitt & Co., Solihull, Birmingham; R. Smith & Co., Worcester; Clibrans, Altrincham; Amos Perry, Winchmore Hill, N.; W. Angus, Penicuik, N.E.; Jno. Derbyshire, Altrincham; Jarman & Co., Chard; John Robson, The Downs, Altrincham; Isaac House & Sons, Bristol; J. Forbes Hawick; B. Dobbs & Co., Wolverhampton; and J. Lambert, Powis Castle, Welshpool.

SILVER MEDALS

were awarded to B. R. Davis & Son, Yeovil; W. & J. Brown, Peterborough; Vincent Slade, Taunton; Pattison, Shrewsbury; Cheal & Sons, Crawley, Sussex; H. A. Watts, Broulyfa, St. Asaph; R. F. Felton, Hanover Square, London, W.; Geo. Prince, Longworth, Berks.

BRONZE MEDALS

were awarded to R. Anker, Addison Nursery, Kensington, W.; G. H. Towndrow, Malvern, Lincs.

AWARDS OF MERIT

were recommended to Amos Perry, Winchmore Hill, N., for Gaillardia "Sulphur Gem"; Hobbies, Ltd., Dereham, for Cactus Dahlias "Daydream" and "White Swan"; Cheal & Sons, Crawley, for Cactus Dahlia "T. F. H. Cook"; R. Wallace & Co., Colchester, for Montbretia Prometheus "Herewood"; Dobbie & Co., Rothesay, for Cactus Dahlias "Bute" and "Good Hope."

FIRST-CLASS CERTIFICATES

were awarded to R. Wallace & Co., Colchester, for Montbretia "Prometheus"; and to Mrs. Seale, Sevenoaks, for Cactus Dahlia "Mrs. Charles Scott."

* * * Notes on a few of the other miscellaneous exhibits must be deferred till our next issue.

THE ROYAL HORTICULTURAL Scientific Committee.

AUGUST 15.—Present: Dr. M. T. Masters, F.R.S. (in the Chair), Dr. M. C. Cooke, Messrs. Gussow, Saunders, Druery, Worsley, and Chittenden (Hon. Secretary).

Harvest Bugs.—Concerning these troublesome pests, Mr. J. S. TURNER writes: "There is nothing like common soap with which to combat harvest bugs. Just dip the soap in water, so as to make it only damp enough to rub, and rub it over the spots. The soda in the soap stops the irritation at once, and the thin film of soap stays the hole the insect has made, and finishes him. If the wrists, knees, and ankles, the parts most usually attacked, be rubbed with coal-tar soap, it will to a certain extent prevent the pest from attacking, but not entirely, and I know nothing that will." Mr. Wright recommends the use of Elliman's Embrocation."

Grubs in Ferns.—Fronde of a variety of the Lady Fern were sent from Wisley, infested with grubs. Mr. SAUNDERS reported: "The grubs infesting the stems of the Fern-fronds are those of one of the sawflies, but I have not been able to get their names. As far as a remedy is concerned, I can only suggest the obvious one of cutting off and burning the fronds."

Blotches on Rose Leaves.—Mr. T. S. DRAKE, of Hoddesdon, sent Rose leaves bearing black blotches caused by the attacks of the fungus *Actinonema rosea*, which is figured and described in the *Journal of the Royal Horticultural Society*, vol. 27, p. 42.

Leaves of Morello Cherry attacked.—Mr. FLINT sent leaves of Morello Cherry badly eaten by the grubs of the Pear-slug, upon which Mr. SAUNDERS undertook to report.

Melon Leaves Shrivelling.—A small Melon plant with shrivelling leaves was received from Lamberhurst. It was the general opinion that the recent transplanting had put the plant under considerably changed conditions, and through this the leaves had become injured.

Fasciated Agapanthus.—Dr. MASTERS showed a much twisted and fasciated stem of white Agapanthus from Mr. FITZHERBERT.

Lilium candidum plumose variety.—Dr. MASTERS showed a specimen of a plumose form of *Lilium candidum*. This curious form was figured by several of the old botanists, but was recently sent to him as a hybrid between the Madonna Lily and Hyacinthus candicans. Dr. MASTERS also showed a stem of *Lilium chalcedonicum* bearing a bulbil in place of a terminal bud instead of occupying the place of a lateral bud as is usual.

Figs Discaed.—Dr. COOKE reported that some Figs which he had examined were badly affected with the fungus *Botrytis cinerea*, which had formed quite a felt upon them.

Monstrous Cucumbers.—Mr. J. CROOK, F.R.H.S., of Forde Abbey, Chard, sent several examples of Cucumbers showing lateral proliferation. The outer rind of the Cucumbers had given rise to a large number of leaves, and in one case to a short stem bearing two other Cucumbers upon it, each of which bore leaves growing from their outer portions. Dr. MASTERS remarked that from a botanical point of view it is easy to understand these monstrosities, since the rind of the Cucumber is really a branch in which the true fruit of the Cucumber is embedded, but what actually induces the production of leaves or branches from the rind in any particular case is so far an unsolved problem. A similar malformation is figured in *Gardeners' Chronicle*, 34 (1903), p. 170.

Dichroism in Antirrhinum.—Mr. SAUNDERS showed a figure of a spike of *Antirrhinum*, in which one flower was of a deep pink colour, while the others were white, splashed with pink. All other flowers on the plant had been of the latter type.

Clematis with leaf-like Sepal.—Mr. SAUNDERS also showed a drawing of a *Clematis* flower in which one of the sepals was green and leaf-like, with the exception of a portion near one edge, which was of the normal colour.

Osmunda Fronds as Food.—Mr. DRUERY showed a specimen of the dried young fronds of *Osmunda regalis* which had been sent to him by the Yokohama Nursery Co. with the following note:—"The young, tender sprouts up to 12 inches or so in length are gathered in the mountains as they appear, and are then boiled and dried. The price is about 40s. per 100 lb. They make a convenient provision for the Army. Several tons are dealt with every year in Japan, where it is used for food. To prepare for eating, soak in water for about ten hours, changing the water several times, then boil. In Japan it is stewed with soy sauce and fish gravy, but any agreeable sauce may be tried with it. It is very tender, and we think you will find it eatable. As shown, the stalks were in the form of roundish, black sticks about 10 inches in length, somewhat flexible and rather tough, and having something of a tarry odour."

Various Amaryllideae.—Mr. WORSLEY showed specimens of the following:—

Zephyranthes candida var. *major*, a fine variety, but rather more tender than the type.

Zephyranthes rosea, a tender species, requiring almost a stove temperature, which produces seeds freely.

Leucojum (Acis) autumnale, a pretty little species, difficult to grow on account of the liking slugs have for it.

Hippeastrum brachyandrum flowers from plants raised from seed, somewhat improved upon the wild stock from Argentina.

Urceoharis Clibrani, first described and figured in these columns. A hybrid between *Urceolina aurea* and *Eucharis grandiflora*. The flower-buds before they open have a yellowish tinge, but afterwards become pure white. The plant never produces seed.

Habranthus advena.—Similar to the type, but with perianth segments about double the width. This flowered in three and a half years from seed.

Lycoris squamigera.—The flowers fade very quickly if exposed to the hot sun, but retain their colour for a considerable time if cut and brought indoors.

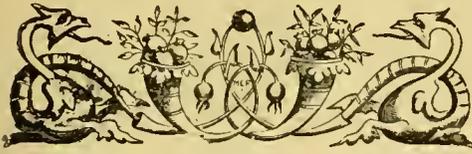

Tritonia rosea.—A pretty species grown from bulbs gathered in the hills above Graytown.

Hybrid Cannas.—Mr. WORSLEY also drew attention to the fact that the hybrids raised between *Canna flaccida* × *Canna* (garden form), known as Orchid-flowered Cannas, were always sterile, but that there was always a much larger number of ovules in the ovary than in that of the garden Cannas, a character which was also to be seen in *Canna flaccida*.

GARDENERS' DEBATING SOCIETIES.

CARDIFF GARDENERS.—The members of the above Association, to the number of over sixty, selected Hereford as the rendezvous for their ninth annual outing on Monday, August 14. The party started from Cardiff in saloon carriages soon after 8 o'clock, and after a capital run arrived at Hereford at 9.37. At King's Acre Nurseries the Cardiffians were received by Mr. M. Peake. The holiday-makers, splitting themselves up in parties of five or more, made a complete tour of the nurseries, which are among the oldest in the kingdom, being established as far back as 1785 by the late Mr. Cranston. The drive back to Hereford, via Mordiford, in the cool of the evening proved very enjoyable, and after an excellent tea the members wended their way to the Castle Green, where the artistic flower-beds were much admired. Mr. Wilson, the Corporation gardener, receiving well-deserved compliments. The party subsequently left for Cardiff by the 8.4 train, arriving there at 10.50. The Hon. Secretary was thanked for the very admirable way he had conducted the arrangements throughout. J. J.

CROYDON AND DISTRICT HORTICULTURAL.—This Society held its annual excursion on Wednesday, when, in ideal weather, a trip was made to the Royal Horticultural Society's gardens at Wisley. On arriving at Wisley the members partook of luncheon at the Hut Hotel. The members visited the Gardens, and inspected the many rare and unique plants, as also those of familiar habit. On the return journey tea was partaken of at the Bear Hotel, Esher. Croydon was reached about ten o'clock, each one expressing his full appreciation of the outing.

ELVASTON CASTLE GARDENS.

AFTER a lapse of twenty years I had the pleasure a few days ago of paying a hurried visit to these far-famed gardens. Elvaston Castle is situated in the valley of the Trent, about 5 miles distant from Derby. The surroundings of the place are flat and commonplace, and consist of well-timbered, rich meadow-land. The situation is not an ideal one for the creation of an interesting and beautiful garden. Yet by the genius and wealth of the Earls of Harrington past and present, and the co-operation of eminent gardeners, out of this comparatively uninteresting material has emerged one of the most unique and interesting gardens in England.

One of the features of the place are the wonderful examples of topiary gardening contained here. This is a form of gardening that does not now appeal with much force to many horticulturists. But when it is carried out, as it has been done at Elvaston, on so gigantic a scale, and kept in such perfect condition, it is certainly impressive. It is laid out on a foundation of a beautiful green and velvety lawn, and there are huge specimens of trimmed evergreen trees, towering up in high proud columns, taking the form of carved arbours, colonnades and figures of many descriptions. The trees are intersected here and there by beautiful glades of well-kept lawns, and lighted up in

many directions by the presence of some of the most perfect and beautiful specimens of golden - coloured Holly we have seen, as well as by many other golden-hued trees and shrubs.

This is a garden of many surprises, consisting as it does of sheltered, cosy nooks and quiet retreats, which afford the most delightful privacy and retirement. Indeed, the whole atmosphere of this garden seems to be one of peace and repose. Another important feature of the pleasure grounds is the wealth of magnificent specimen Conifers, mostly planted some fifty or more years ago under the direction of the then Earl of Harrington's gardener, the late Mr. Barron, of Borrowash, a gentleman well known as one of the most distinguished landscape gardeners and horticulturists of his time. Many of these trees have now attained to immense heights and noble proportions, adding much dignity and grandeur to this fine domain. Not the least important of the improvements effected by planting was the formation of a broad avenue of trees opening out a splendid and distant vista from the windows of the house, and reminding one a little of the Long Walk in Windsor Great Park.

HARDY FRUITS.

Another important aspect of gardening which has received much encouragement, especially from the present Lord Harrington, is that of fruit-growing, which has been developed to a very high degree of perfection by his lordship's head gardener, Mr. Goodacre, during the past thirty or more years. There is no occasion to enlarge on this point, as his successes at our best national and international shows for that length of time testify to his skill far more eloquently than any words of mine could do. In speaking of the fruit at Elvaston as I saw it the other day, much will have to be left unsaid, as this notice is only a brief and passing bird's-eye view of the resources of this notable garden.

Knowing something as I do of the climate of Derbyshire, I have no hesitation in saying that few, if any, counties in England have a more inhospitable or a colder climate, or a climate more inimical to the successful growth of hardy fruit-trees than have many portions of this county. Yet, strange to say, through some freak of the weather, this year the crops, especially on wall-trees, are better in this part than in any of the southern counties I have seen. This is particularly true in regard to Pears. Apples also, although only a partial crop, are better than they are in the south, the Codlin section especially; and what surprised me greatly was to find a large tree of the variety Gascoyne's Scarlet Seedling borne down with the weight of an enormous crop. With the exception of last year I was told that equally heavy crops of this variety had been obtained for the past nine years. Friends in the cold Midlands should make a note of this. These few remarks on the out-of-door crops are by the way. It is in the cultivation of

FRUITS UNDER GLASS

that the Elvaston Gardens have taken so high a position, and especially in the production of high-class fruits for exhibition. Many gardeners have often wondered how the splendid samples of Apples, Pears and Plums,

which are characteristic of the Elvaston collections of fruit, were grown. Had they seen the five hundred or more specimen trees of these and other fruits grown in pots in cold orchard-houses of almost unlimited extent, they would wonder no longer.

The fruit has been gathered from most of the pot-trees of Peaches, Nectarines and Cherries. But of Apple, Pear and Plum-trees there were some magnificent examples of culture to be seen.

The Apple trees are now mostly placed out-of-doors in sunny positions against walls in order to improve the colour of the fruit, and so well has this object been attained that extraordinary high colour is the result. One Apple amongst many on a tree of Ribston Pippin had taken on such a deep crimson colour as to be altogether unrecognisable. The varieties favoured here for pot-culture are few, and include such as Cox's Orange Pippin, Ribston Pippin, Washington, Beauty of Bath, &c.

Of Pears in pots the result is equally satisfactory; many of them are now placed in various positions and aspects against walls out-of-doors, and they are well protected by netting, those requiring to be retarded against north walls, and those to be hastened against walls having a warmer aspect. Few are aware of the great influence exercised in improving the colouring of fruit by its exposure to sun and air out-of-doors. I noticed a striking instance of this at Elvaston, where two trees of the variety Louise Bonne of Jersey were growing side by side on a wall, one under glass, and the other out-of-doors. The latter bore a rich ruddy colour, while the former was of a shade of light green.

Plums in pots are grown grandly also. I have seen most of the Plum-trees in pots exhibited in London during the last five years, and those of Mr. Goodacre would compare favourably with the best of them.

I might say much of the Peaches, Nectarines, Figs, Melons, &c., but time and space forbid.

THE GRAPE-VINES.

I now hasten briefly to notice the crown and glory of the fruit at Elvaston, namely the Grapes, and especially late Grapes, with which Mr. Goodacre's name has been so long and conspicuously associated as a successful exhibitor. The summer crops of Grapes are past their best, but there are some fine bunches of the following varieties still left—Muscat Hamburg, Muscat of Alexandria, Black Hamburg and Madresfield Court. The quality, size and finish of these are very fine, and I presume they are kept back for exhibition.

Our time having now nearly expired we hasten to view the comparatively new, large and lofty block of vinerias a little distance away, in which the late Grapes are grown. Some of these are devoted exclusively to black varieties which are known to succeed under similar conditions of temperature, &c. Such immense clusters as are seen here of Gros Colmar, Gros Maroc, Black Alicante and Alnwick Seedling are very seldom met with, many of them weighing from five to seven pounds each.

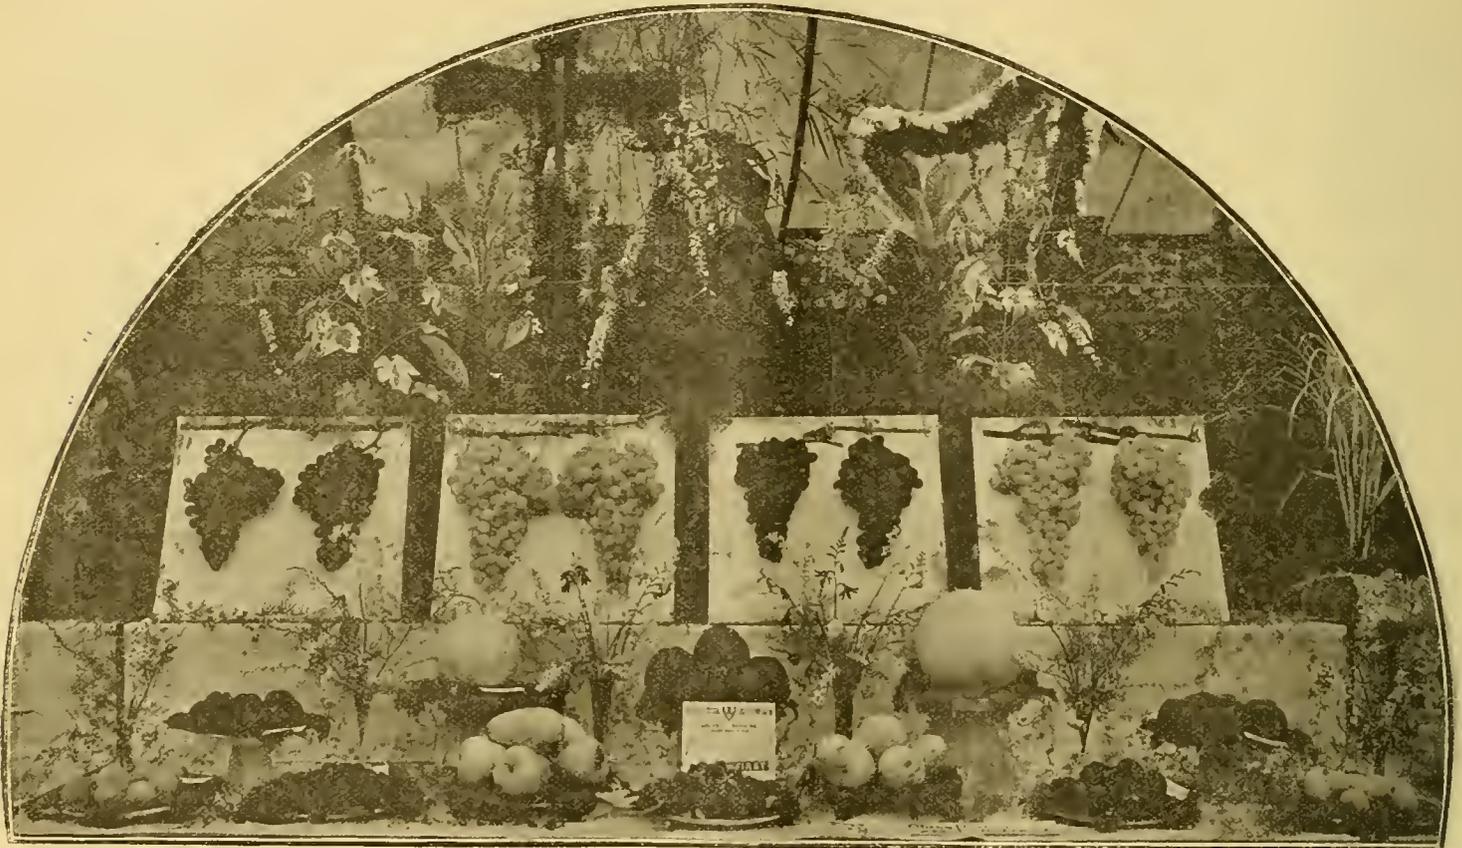

The Vines are clean and in a perfect condition of health, and by the time the full development of berries and blooms has taken place, say two months hence, they

will, indeed, be a treat to see: many of them are now jet-black, and fit for exhibition at any time. A circumstance in Grape-growing was pointed out which is worth noting as an encouragement to those who may wish to remove permanent Vines of old standing from one place to another, but are afraid to do so. An eleven-year-old double-rodged Black Alicante Vine was replanted in March last. So successful had the operation been that the Vine bore no trace

are in excellent health, the foliage being of fine size and colour, and splendid texture, showing that the crop, although so heavy, will be perfectly ripened in due course. Indeed, many of the bunches are ripe now. If we had seen nothing else to admire at Elvaston besides those grand winter Grapes we should have felt well repaid for the long journey we took to see them.

I have to thank Mr. Goodacre's son for his kindness and courtesy in showing me round the garden in his father's absence, and

Musa Cavendishii, a plant of much more dwarf habit, seldom exceeding 5 to 6 feet high, and producing smaller bunches and smaller fruits, which are thinner-skinned than the former and possess a more delicate flavour. It is known as the Chinese Banana, and besides the superior flavour of the fruit it has many characters to recommend it for general cultivation. This form is now being extensively grown at Barbados and shipped to this country in increasing quantities as Barbados Bananas. Another indication that this species is attracting attention for more general cultivation may be found in the following extract from the

[Photographed by Mr. Waller W. Naunton.]

FIG. 63.—THE SHREWSBURY SHOW: LORD HARRINGTON'S FIRST-PRIZE EXHIBIT IN THE CLASS FOR A COLLECTION OF SIXTEEN DISHES OF FRUIT.

(See p. i. of the Supplement to our last issue.)

whatever of having been subjected to such violent disturbance. The crop it bore was not quite so heavy as could be seen on the others, but otherwise the plant was as robust as any in the house. Growing with these Grapes were one or two rods of that noble-looking white variety, Chasselas Napoleon; these were very fine in bunch and berry, and I have no doubt will be seen and admired on the exhibition table before the season is over.

Following a good example, we have kept not the best wine but the best Grapes until the last, namely the Muscat vinery and its contents. I have not the dimensions of this house before me, but suffice it to say that the structure contains upwards of a thousand bunches of magnificent Grapes. The bunches would average all round 4 lb. each, a great many of them would turn the scales at 7 lb. or more. Each vine carries from nine to ten of these huge clusters. The Vines

also Mrs. Goodacre for one of the best cups of tea I ever tasted (a real Welsh cup of tea she called it). No wonder the Welsh people are called a nation of tea drinkers if all Welsh tea is as good as this was. O. T.

BANANAS.

THE VARIETIES FROM JAMAICA, BARBADOS, AND CANARY ISLANDS.—The differences in the size and quality of the Banana fruits imported from Jamaica and the Canary Island is a question that has recently been asked by a correspondent. In reply I would say that the Jamaica and Costa Rica Bananas are the produce of *Musa sapientum*, which grows to a height of some 20 feet or more, and is found in most tropical countries. It is now cultivated under many varieties, that grown in Jamaica being known as the Gros Michael. The bunches and individual fruits are much larger and have thicker skins than those grown in the Canary Islands, which are the produce of

Journal of the Jamaica Agricultural Society for June, 1904:

"After the storm of November, 1899, and the hurricane of August, 1903, when so much damage was done to Bananas, we called attention to the dwarf Banana, *Musa Cavendishii*, commonly called here the Chinese Banana, and its stout wind-proof growth. It easily withstood the rain and wind-storms of November, 1899; it even withstood the hurricane of August, and both times a good quantity of this variety was under our personal observation. In Fiji, where the people have always depended largely upon the Banana for food, and which now supplies the Australian and New Zealand markets with this variety, the introduction of the dwarf Banana in place of the imposing-looking tall varieties saved the people from being sometimes on the verge of famine, as they formerly were, through losses by storms recurring at short intervals. This variety is said not to keep so well as the Martinique. We have not found it so. It grows better on

poorer soils, and does not require so much moisture. It certainly does not sucker so profusely as the Martinique; but is not that an advantage, so long as it gives a succession of one or two, which it never fails to do? It can be planted 6 feet apart. At present our market in the United States does not want it, although it is the variety which goes from Hawaii to San Francisco, and supplies the Pacific coast of North America. But in the British markets it is preferred because it is now being supplied from the Canary Islands, and is also being shipped in small quantities, and successfully, from Barbados. The dwarf Banana ought to be taken up and cultivated by those who would make a specialty of supplying the British market. It can be grown on this plan with a far more moderate supply of water than the Martinique."

This extract fairly sets out the differences and advantages of the Canary Island or Barbados Banana over the Jamaica and Costa Rica kind. We are not in a position to say what number, or if any other varieties, are grown in the Canaries.

With reference to the composition of the Banana, the following quotation from Professor Church's *Handbook on Food*, forming one of the South Kensington series of "Science Handbooks," may be useful:—

"The Banana is a nutritious food, having less water and more nitrogenous matter than is commonly found in fresh fruits. It contains, when ripe, much sugar but very little starch. Freshly-picked Bananas contain:

	In 100 parts.	In 1 lb.
	oz.	gr.
Water	74.9	11 361
Albumen	4.8	0 335
Sugar and pectose ...	19.7	3 66
Fat	0.6	0 42
Cellulose	0.2	0 14
Mineral matter	0.8	0 56

For 1 part of flesh-formers in freshly-peeled Bananas there are 4 parts of heat-givers, reckoned as starch. One lb. of Bananas might produce at the most $\frac{2}{3}$ oz. of dry, nitrogenous substance of muscle or flesh." John R. Jackson, *Claremont, Lympstone, Devonshire.*

VARIEGATED CONIFERÆ.

(Concluded from p. 164.)

JUNIPERUS.

Juniperus chinensis var. *albo-variegata* is a dense-growing plant, possessing no outward character of its parent, being very broad in proportion to its height, and of a bright, glaucous tint all over, except at the ends of the shoots, which are irregularly marked with silvery-white. It is a very handsome plant, but not very popular.

J. chinensis var. *Youngi aurea*.—This is a golden form of the type, but it is a rather slow-growing and tender plant, especially in a young state. When it has attained a fair size it is a singularly handsome plant with its bright golden hue and graceful, feathery foliage.

J. japonica aurea.—Under this name a plant is known in nurseries which I cannot identify with any species except it may be *J. chinensis*. In habit, however, it differs materially, being of a spreading, semi-horizontal nature, somewhat approaching the common Savin, though much larger. The main branches are usually two to four in number, and grow in the form of an extended fan. The foliage is fine, and strongly tinted with bright orange colour. It is a good subject for a corner, the showiness of the plant being all on one side.

J. communis var. *alpina aurea* is a dwarf, spreading form of the common Juniper, with bright, bronzy-yellow foliage. It makes a splendid plant for the rockery, and also in the shrubbery, where a low patch of colour is desired. It will grow almost anywhere, but loses colour in the shade.

These Junipers are all practically indifferent to soil; but a moderately light loam and a full exposure to the sun suit them best.

THUYA.

T. occidentalis var. *aurea (lutea)*.—This is a bright-yellow form of the well-known American Arbor-vitæ, possessing the thin, upright habit of the parent plant. The colouring is deep and uniform all over the plant; but it must have a good moist soil to grow in, or it will become very thin and ragged.

T. o. var. *Ferracaneana*.—In a young state this form possesses very little colour to recommend it, but with age it assumes a pleasing tint of pale bronzy-yellow, which is very striking in winter when seen amongst darker-foliaged subjects, or under a low winter sun. It is a fast grower, succeeding almost anywhere, and deserves to be more generally planted than it is.

T. plicata (Lobbi, or *gigantea* of gardens) var. *zebrina*.—This is a comparatively recent introduction, and is an upright, fast-growing plant with cross stripes of bright yellow colour. It is nearly as quick a grower as the type, but makes a far denser and handsomer specimen.

T. orientalis var. *semperaurescens*.—This is a slow-growing plant, rarely attaining more than 4 to 6 feet in height, but its colouring during the winter months leaves nothing to be desired. The foliage assumes an intensely bright golden-bronze hue, which, seen under a low winter sun, resembles a flame of fire more than anything else. It should not however be planted in a low, damp position, as the high colouring renders it rather tender, and liable to be cut by frost, especially if the foliage is at all wet.

These Thuyas should all be grown on moderately dry ground, except where otherwise stated, as they are fairly easy to grow, and the colouring is enhanced on light soils.

Libocedrus decurrens var. *variegata*.—This resembles the type, except that it is variegated with splashes and stripes of bright yellow, which are fairly constant, even when the plant has attained a height of 20 feet or more. It can be grown in almost any soil or situation, but is a difficult subject to transplant.

Sequoia sempervirens var. *albo-spica*.—A handsome plant, but unfortunately it is rather tender, not that it gets killed by frost, but, commencing to grow early in spring, it continues till late in autumn, so that the ends of the shoots get cut by late or early frosts. I have seen plants about 10 feet high that were twenty years old, with half a dozen or more leaders. In districts where it will thrive it forms a graceful pyramidal plant, with the ends of the shoots tipped with silvery-white. A deep, well-drained soil and an open, sunny situation should be provided.

Picea excelsa var. *finendonensis* resembles the common Spruce in growth and habit, but the upper sides of the branches are of a brilliant silvery-white, which is very pleasing when seen under a winter sun. It requires a deep, moist soil.

Cedrus Deodara var. *albo-spica* is a form of the Deodar, having the ends of the shoots tipped with silvery-white. In habit it is denser than the type, assuming a broadly conical rather than a pyramidal outline. What its ultimate height will be it is impossible to say at present, but from present appearances I should say it will not attain to a height of more than 20 feet, and be rather broad in proportion. It requires a deep, rather light soil, and an open, sunny situation, as if at all crowded by other plants this variety is liable to lose its foliage and become thin and ragged.

C. D. var. *aurea*.—This is a new form of the Deodar, with bright yellow foliage, but it is impossible to say much about it at present, though from its appearance it is likely to be a decided acquisition to our gardens.

Pinus sylvestris var. *aurea* is a golden form of the common Scotch Pine, and makes a cheerful

bit of colour in the pinetum in winter. It is green in summer, but assumes a bright yellow tint in winter. It is a slow grower, but does well almost anywhere.

PROPAGATION.

The variegated forms of *Cupressus*, *Thuya*, and *Juniperus* can be increased by cuttings, except in the case of the more delicate ones, which thrive best when grafted on stocks of the species they belong to. Cuttings are made in August from the half-ripened shoots, inserted in sandy soil, and put in a cold frame, the atmosphere of which is kept close for a time. They will soon make roots, and should be left until late spring before planting them out, merely keeping them from frost during the winter, though two or three degrees do not hurt them. The other variegated Conifers mentioned should be grafted on stocks of the species they are forms of. It is sometimes advised to use a certain stock for certain Conifers, as *Abies pectinata* for any Silver Fir, but while this answers as a means of propagation, it does not always follow that the plants will grow and thrive afterwards. For example, *Cupressus macrocarpa* var. *lutea*, when grafted on *C. macrocarpa* or *C. sempervirens*, grows nearly as fast as a seedling plant, but when worked on *C. Lawsoniana* it takes years to make merely a stunted bush about 3 feet high. *J. C., Bayshot.*

TREES AND SHRUBS.

HYPERICUM PATULUM VAR. HENRYI.

The ordinary form of *Hypericum patulum* is fairly well known in south country gardens, being one of the most attractive of the St. John's Worts, also one of the parents of the valuable *H. Moserianum*. It is, however, not so hardy as could be wished, for it dies back to the ground nearly every winter and is frequently severely injured. This new variety, introduced from China by Dr. Henry in 1899, is a hardier and superior plant. It is sturdier in habit than the typical *H. patulum*, and so far has not suffered in the least through frost. The leaves, ovate and 2 to 3 inches long, are dark-green above and glaucous beneath. The flowers are of the rich glowing yellow colour common to this group of *Hypericums*, and $1\frac{1}{2}$ to 2 inches across. In habit and vigour this variety approaches *H. Hookerianum* (*oblongifolium*), but it is more bushy and better furnished than that species, and the flowers are rather larger. It has the two-edged flower-stems and more erect styles that distinguish *H. patulum* from *H. Hookerianum*. The new variety is flowering freely now in the Kew arboretum. *W. J. B.*

OAK AND YEW FORMING ONE TRUNK.

In the park of St. Pierre, about four miles from Chepstow, on the crown of some rising ground, is a colony of old Yews, interspersed with Oaks and other trees. There are about sixty of these Yews, some dead, some dying, and others in vigorous health. The history of the trees is obscure, but doubtless they were all planted at the same time. The tallest is between 60 and 70 feet in height, but the majority are about 50 feet high. The girth of the largest at 5 feet from the ground is 22 feet 6 inches. While one of these trees was being measured it was noticed that the bark on one half was different to that on the other portion, and on retiring to a little distance the branches of an Oak were seen overtopping those of the Yew. On close inspection it was found that a Yew and an Oak had grown so closely together that they formed a solid trunk to a height of 5 feet. The girth of the combined trunk at this height was just over 21 feet. It is a curious fact that none of the St. Pierre trees are hollow, as is generally the case with old Yews. *S. W. Fitzherbert.*

THE VEGETATION OF PASTURE LAND.

In the *Philosophical Transactions of the Royal Society*, vol. 173 (1883), is contained a very elaborate paper on the botanical results of experiments on the mixed herbage of permanent meadow at Rothamsted.* In that paper are discussed the results obtained on two unmanured plots and on several plots treated with manures of varying nature and of various strength for a period of over twenty years. These details are co-related with the meteorological records for the same period, and especially with those relating to certain separation or census years, when a minute investigation of component species of each plant was made. The conformation and habit of growth of each plant, so far as they are relevant, were also given in this paper.

Speaking of the botanical results only, we may say that a census of the plants found growing on all the plots, manured or otherwise, or in the hay derived from them, was made in different years by Mr. W. Sutherland, Mr. R. Keenan, Mr. W. B. Hemsley, Mr. Walter Davis, always with the invaluable aid rendered by Mr. Willis. These experiments are still going on and records are duly kept. Our present intention is simply to call attention to some of the salient results concerning the vegetation of the two unmanured plots. We must refer the reader to the paper above cited for full details, including those relating to a fourth separation year, 1877, not referred in the following notes, and for a discussion of their significance. The figures hereinafter given do not in all cases tally exactly with those in the more elaborate paper. There are many reasons for these discrepancies, which need not here be entered into, inasmuch as they do not affect the general conclusions.

The accompanying diagrams, made for our own convenience whilst engaged in collaboration with the Rothamsted heroes, show approximately the varying constitution of the herbage on the two unmanured plots (3 and 12) in the experimental grass plots, as determined by the census taken in the years 1862, 1867, and 1872 respectively. In each case the left-hand vertical column refers to the year 1862, the central one to the year 1867, whilst that to the right shows the condition of the plots in 1872. In the paper referred to the results of a fourth complete census are also given. In all cases the thin line refers to plot 3, the thick black line to plot 12. These details are interesting as showing the diversity in the plots dependent on inequalities of growth from variations in climatal conditions and the varying habits of the plants. As no manure has been applied to these plots for many years, the changes in the vegetation cannot be attributed to any other than climatal causes and individual peculiarities of the plants themselves. They afford indications of the nature of the struggle for existence or supremacy among plants growing together in association, independently of any differences in the quality or quantity of the food supply.

According to the last-issued summary (1905) the average produce of hay per acre on plot 3 has been 21.3 cwt., or, if the amount of the second crop be added, 22.1 cwt.; whilst in 1904 the total was 28.4 cwt. per acre—a considerable increase over the average, again showing the effect of season.

The figures for plot 12 are 24 and 24.9 cwt. on the average; whilst in 1904 the total amount is given as 28.7 cwt.—almost exactly the same as on plot 3. The mean amount for both plots is thus a little more than 24 cwt. per acre.

Turning now to details, fig. 1 shows the total number of different species of flowering

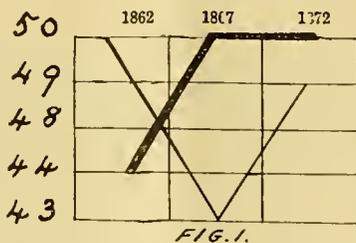

FIG. 1.

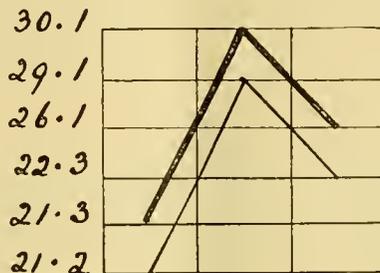

FIG. 2.

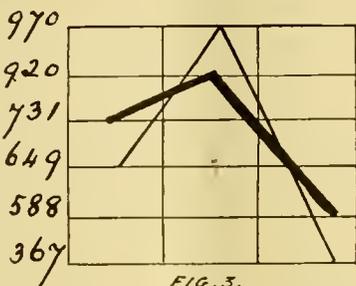

FIG. 3.

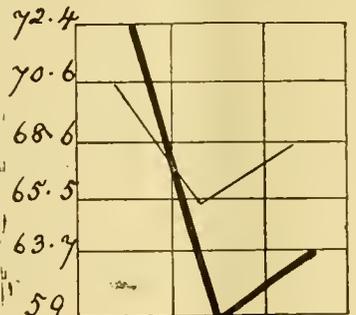

FIG. 4.

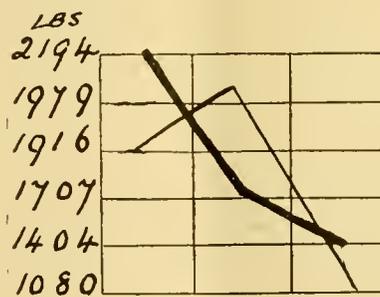

FIG. 5.

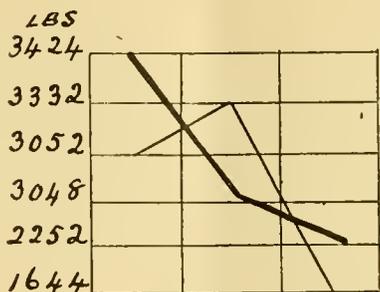

FIG. 6.

plants detected on plot 3 and on plot 12 in the three census-years 1862, 1867 and 1872. The thin line, representing the state of affairs in 1862 on plot 3, shows that on that plot there were fifty species in 1862, forty-three in 1867, and forty-nine in 1872. On plot 12 there were forty-four species in 1862, fifty in 1867, and the same number in 1872, so that the total number of detected species on the two plots taken together varied from forty-three to fifty, a mean of a little over forty-six. The great drop on plot 3 in 1867 would seem to indicate that certain species were dominant in that year and crowded the others out. Doubtless all fifty species existed every year, but some were in a dormant condition, or at least were either not represented in the hay or were not observed on the plots during the course of the season.

Fig. 2 shows the percentage of "miscellaneous" weeds in the three years, the "miscellaneous" including all flowering plants other than grasses and Leguminosae. The lowest percentage was 21.2 on plot 3 in 1862; the highest, 30.1 on plot 12 in 1867, the mean of the two being rather over 25. The conditions on the two plots must have been, as will be seen, very nearly alike.

In fig. 3 the total weight of the miscellaneous plants is shown varying from 367 lb. on plot 3 in 1872 to 970 lb. on the same plot in 1867.

In fig. 4 is shown the percentage of grasses to the whole herbage—the lowest percentage 59 on plot 12 in 1867, and highest, 72.4, on the same plot in 1862. The conditions are the reverse of those relating to the miscellaneous plants shown in fig. 2.

Fig. 5 indicates the total weight of the grasses in the two years, which varied from 1,080 lb. on plot 3 in 1872 to 2,194 lb. on plot 12 in 1862.

Fig. 6 shows the weight of the total produce, varying from 1,644 lb. on plot 3 in 1872 to 3,424 lb. on plot 12 in 1862. The curve for the grasses and for the total herbage is thus seen to be approximately the same (compare fig. 5).

Fig. 7 refers to the percentage of the Leguminosae (Clovers, &c.). Here the lowest percentage (5.35) occurred on plot 3 in 1867; the highest (10.7) in the same year on plot 12; so that there was in this year 1867 a directly opposite condition in the two plots as regards Leguminosae as there was also in the total number of species, as shown in fig. 1—owing, no doubt, to some individual differences between particular species which were not obvious on the surface.

Fig. 8 shows the weight in pounds of the Leguminosae, varying from 148 lb. on plot 3 in 1872, to 329 lb. in 1867 on plot 12, thus corresponding closely with the curve in figs. 7 and 11.

Fig. 9 shows the number of hundredweights per acre, varying from 14½ cwt. on plot 3 in 1872 to 30½ cwt. on plot 12 in 1862. The notes as to this particular figure are incomplete.

Fig. 10 shows the mean percentage of grasses to the whole of the herbage, varying from 56.02 on plot 12 in 1867 to 65.70 on plot 3 in 1872. The two plots correspond closely. The curve is nearly in conformity with that on plot 4, also representing the grasses.

In fig. 11, as in fig. 7, are given the percentages of the Leguminosae, varying from 5.35 in 1867 on plot 3, to 10.79 in the same year on plot 12, thus showing an opposite condition of affairs on the two plots in the same year. See also fig. 8. The diversity between these plants and the grasses is also marked. Compare figs. 10 and 11.

In fig. 12 are shown the percentages of miscellaneous weeds, varying from 21.2 on plot 3 in 1862, to 30.19 on plot 12 in 1867. The details of the two plots are here pretty uniform.

Fig. 13 shows the percentage of Ranunculaceae (Buttercups), varying from 2.02 on each plot in 1867, to 4.89 on plot 3 in 1862, so that the success of the Buttercups on that plot in that year was

* By Sir J. B. Lawes, Bart., Dr. (afterwards Sir) Henry Gilbert, and Dr. Maxwell T. Masters. See also *The Rothamsted Experiments*, by W. S. Fream, p. 133; *Plant Life*, by Dr. Masters, chap. vii., "The Battle of Life."

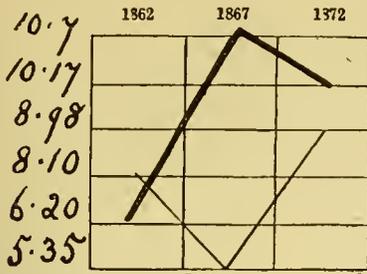

FIG. 7.

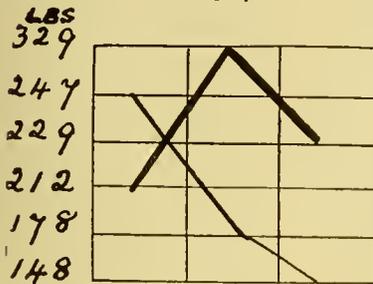

FIG. 8.

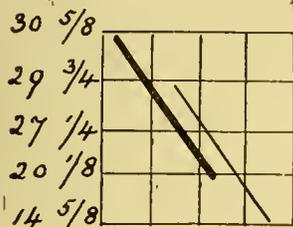

FIG. 9.

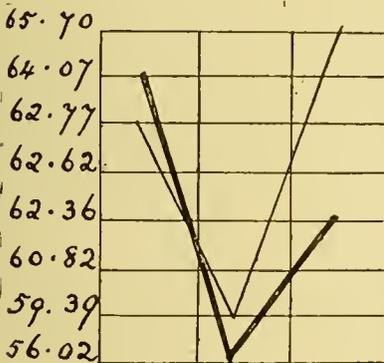

FIG. 10.

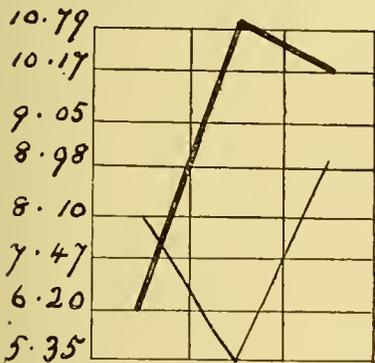

FIG. 11.

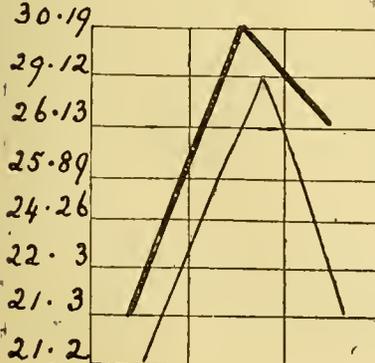

FIG. 12.

very marked. The general character of the curve is like those of figs. 4 and 10 (grasses).

Fig. 14 shows the great uniformity in the growth of the Umbelliferae for the two years, the percentages varying from 2.50 on plot 3 in 1862, to 6.62 on plot 12 in 1867. It also shows that the requirements of the Umbelliferae conform to those of the miscellaneous weeds generally—see figs. 2 and 12, but are just the reverse of those of the Ranunculaceae.

In fig. 15 are given the percentages for the Compositae. The two plots are shown to be pretty uniform, the range varying from 1.98 in 1862 on plot 3 to 5.34 on the same plot in 1872, and from 2.86 on plot 12 in 1862 to 7.61 in 1872.

Fig. 16 shows the same details in the case of the Plantains (Plantago). Here again the condition is nearly the same in the two plots, the lowest (0.41) being on plot 12 in 1872, the highest (10.73) in 1867 on plot 3, the range being from 0.41 to 10.73. The curve is almost the same as that for the weight of miscellaneous plants (fig. 3).

Fig. 17 gives the percentage details for Rumex acetosa: the lowest percentage was 1.40 on plot 3 in 1862; the highest, 3.61, on plot 12 in 1867.

Fig. 1 shows the number of species observed on the two unmanured plots in the years 1862, 1867 and 1872.

Fig. 2 shows the percentage of miscellaneous flowering plants other than grasses and Leguminosae on the same plots in the same years.

FORESTRY.

BELGIAN FORESTRY.

THE recent excursion of the Royal English Arboricultural Society to Belgium under the guidance of Professor Fisher gave those members taking part in it a splendid object-lesson of what can be done by an energetic and progressive Government Department of Forestry. Belgium is a small country, only about one-eighth the size of Great Britain, and yet she is able to show a system of state and communal forestry which, to say the least, is a striking contrast to what can be found at home. Under Dutch rule Belgian forests were said to be badly managed—many of the state forests being either sold outright or their timber turned into money—but after Belgium obtained her independence she was not long in putting things to rights. It was not until 1854, however, that the Code Forestier, by which Belgian forests are now administered, came into existence. While allowing full liberty to the private owner, it controls the system of management adopted in all forests belonging to public bodies, chiefly represented by the communes, and which cover altogether about half a million acres, or rather more than one-third of the total area of woodland in the country, the State forests occupying only 62,000 acres, while the private woodlands extend to 823,000 acres, representing altogether about 17 per cent. of the total area of the country.

This forest area occupies all classes of land, from deep good loam, which might fairly be claimed by the agriculturist, to peat-bog, or thin rocky land at high elevations. The greater part, however, occupies land of little use for anything but forestry purposes, also some really good land that has been covered with forest from early times.

Mountain land above the limits of tree growth does not exist, so that the half million acres of waste land represents rather a large proportion of the total area. This unsatisfactory feature is however being recognised by the Government, and since 1897 it has acquired and planted over 15,000 acres at a cost of £212,000.

During the last twenty years the Forest Department has been chiefly engaged in the conversion of

the large areas of coppice or coppice with standards into high forest. In Belgium as in England, ordinary coppice is no longer a paying crop, and an attempt is made either to replace the coppice with timber trees altogether, or to increase the proportion of Oak standards and the length of the coppice rotations generally, so as to obtain produce which will furnish pit-wood, if nothing larger.

In the communal forests the coppice with standard system is still favoured to a great extent, as it allows returns to be made at short intervals and according to the requirements of the communes for money. Exceptional expenditure, such as the building of a church, the laying down of a new water-supply or drainage system, or other work of that nature, is met by making a heavier fall of timber in the communal woods; and the great advantage of such a system to the present generation is obvious. The Mayor of the village of Poix, visited by the Society, is also the head woodman of the commune, and what better custodian of the woods and the villagers' interests combined could possibly be found?

The principal high forest crops are Beech (either with or without Oak), Spruce, and Scotch Pine. In the Ardennes large areas of pure coppice exist, and here and there may be seen the combination of agriculture and forestry, which is known as *sartage*, and which consists in sowing Rye or other cereals between the shoots of the underwood after each cutting of the latter, but the labour involved can hardly make the system profitable. The Conifers are usually grown on short rotations of thirty to forty years, being used chiefly for pitwood, pulp, &c. Beech and Oak form the bulk of the heavy timber, the former being particularly fine at moderate elevations, while Spruce does well on the higher ground. Scotch Pine rarely succeeds after the fiftieth year in the Ardennes, and so far as was seen its chief function seemed to be the reclamation of the worst classes of land, rendering them fit for Beech or other hard-wood crops. Of exotic trees, Weymouth Pine gives great promise of becoming useful, and succeeds well on the highest ground, it being evidently less affected by wind than is the case in England. For wind-breaks *Picea alba* and *rubra*, *Pinus Cembra*, &c., are used. A striking feature throughout the country was the extensive planting of roadside trees, chiefly Wych Elms, which has been carried out by the Department of Roads and Bridges during the last fifty years. Railway embankments were also largely planted with Cobbett's friend, the Locust-tree, but appeared to be chiefly treated as coppice.

The growth of all species proved clearly that Belgium has a better climate for timber-growing than has the greater part of England, probably due to its geographical position. Wind is said to be troublesome, but is evidently not of that persistent nature which affects tree growth so much with us.

Ground game in the shape of rabbits was not plentiful, although the foresters complained of the damage they did, as in duty bound. But in some of the State forests, deer do a good deal of damage, so that England is not the only country in which forestry is handicapped by game, as we are apt to think at times. *A. C. Forbes.*

(To be continued.)

REPORT ON THE TRIVANDRUM MUSEUM.—

We have received the Report on the Trivandrum Museum and Public Gardens for 1903-4. The want of an efficient water supply is found a great disadvantage. Various fishes and birds were obtained for the collections. Much work was done in the public gardens in spite of the lack of water, and there is a good record of plants that flowered, and of various species that were newly introduced into the grounds.

The Week's Work.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Dr. CORBET, Impney Hall Gardens, Droitwich.

Cucumbers.—A sowing of some approved variety, such as a good strain of Telegraph, which is still difficult to surpass, should be made at the present time. Another sowing should be made about the middle of September to obtain plants for furnishing fruits during the winter months, and as these plants will have a long period of growth the old material from the hotbeds should be entirely cleared out and the pits thoroughly cleansed of woodlice and other insects. Have young healthy plants in readiness for planting when the beds are prepared. Do not use a large quantity of soil for planting, but rather give light top-dressings of a suitable compost at short intervals afterwards as the roots appear on the surface. Encourage the plants to make sturdy growth by giving free ventilation on all favourable occasions. Plants growing in pits and frames must have the old growths and decayed leaves removed and should be encouraged to develop young growths. Ventilate the structure early on bright mornings, closing the same early in the afternoon with sun-heat and plenty of atmospheric moisture present. Apply top-dressings of rich soil, also liquid-manure, to plants that are showing signs of exhaustion, and place fresh linings of litter to the frames in order to maintain a suitable degree of bottom-heat.

Tomatos.—Plants required for winter fruiting should be potted into 8-inch pots as soon as they require a shift and be stood out in the open, unless the weather is wet and unsettled, when they should be placed in a cool pit, given plenty of room, and full ventilation. Exercise much care in watering the plants. A mixture of good fibrous loam, lime rubble, and burnt ash, with a sprinkling of bone-meal, forms a suitable compost. Pinch out all side laterals as they appear, and have the plants neatly staked.

Cherries.—The foliage on trees in pots must be kept clean by freely syringing with clear water. The plants require to be well supplied with water. Late varieties that are planted out, and which have been kept on the dry side should receive liberal supplies of liquid manure or clear water as soon as the fruit is gathered, and the foliage thoroughly cleansed of insects by some suitable insecticide.

Plums.—Fruits of early varieties have been gathered by now, but trees of midseason and choice late varieties will still be yielding an invaluable supply now that fruit is scarce. The trees require liberal ventilation, and careful attention to watering, using clear water only on those trees whose fruits are ripe or ripening. Syringe and damp all available spaces in the house without wetting the fruits.

PLANTS UNDER GLASS.

By A. BULLOCK, Gardener to E. J. WYTHES, Esq., Copped Hall, Epping, Essex.

Cleansing of Structures.—It is very necessary to periodically cleanse all structures in which plants are cultivated at this season of the year, and before housing the plants grown out-of-doors during the summer months advantage should be taken of the opportunity afforded to have this work done thoroughly. Heated houses in particular must not be neglected in this respect. In the first instance thoroughly scrub all the woodwork with hot water and soft or carbolic soap. In cases where it is practicable to syringe the walls and woodwork of structures with paraffin and soapy water without fear of causing injury to the plants, let this be done, and afterwards whiten the walls with lime-wash to which a little paraffin has been added. Attention to these matters will amply repay for the trouble involved.

Stephanotis.—These plants will now have completed their growth, and therefore, if they are cultivated as specimens in pots, remove them to cooler quarters and lessen the supply of water afforded to the roots. Full exposure to the sun's rays is very necessary to ripen the growths thoroughly, and if this be done it will be sure to cause them to bloom freely.

Bougainvilleas.—If any Bougainvillea is planted out in a conservatory or similar structure, let

watering at the roots be gradually reduced to encourage resting, but this must not be done suddenly otherwise the plants will suffer a severe check. Admit more air where practicable; this will also tend to induce resting. Plants in pots should be removed to a cool, freely ventilated house, and treated similarly to those planted out in respect to the supply of water.

Tuberoses.—Little difficulty need be experienced in perfectly cultivating these sweet-scented flowering plants, but failure sometimes results from making a wrong start, and from employing too much heat in the early stages of growth. Let the bulbs be potted moderately firm in a compost of loam, leaf-soil, and silver-sand, used in equal proportions. This compost should be in a sufficiently moist condition that no further water will be needed until the bulbs commence to make roots. Place the pots containing the bulbs in a frame on a cool base composed of ashes, where they may remain until growth commences. The plants should then be removed to warmer quarters. At no time should very hard forcing be employed. If a succession of flowers is required, let batches of bulbs be potted at suitable intervals proportionate with the requirements of the garden.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen, S.W.

Odontoglossum crispum.—A very suitable rooting medium for this plant and for most of the hybrids from this species is a compost of peat two-fifths, sphagnum-moss two-fifths, and good Oak leaves one-fifth, adding some silver-sand and crushed charcoal during the mixing of the ingredients together. The peat employed need not be deprived of all the fine particles, neither need many of the Fern-rhizomes be removed. The Oak-leaves should be in a moderately dry condition, not much decayed, for the tougher they are the better; but remove all sticks and other undesirable matter. Let such a mixture be prepared at the present time, Fern-rhizomes be dried and got ready for drainage material, and sphagnum-moss be chopped for surfacing the plants.

When to Pot the Plants.—The fact that Orchid roots when taken from their surrounding materials and put into fresh compost seldom thrive afterwards, should be remembered when considering the needs of a plant. So long as a plant has sufficient room to develop, and appears to be in a satisfactory condition, a renewal of the surface materials just prior to the plant's making new roots should suffice. Plants that have reached the sides of their receptacles, or whose rooting medium is unsatisfactory, should be repotted when the new growths have become an inch or two in length.

How to Pot.—Carefully turn out the plant and pick away a large portion of the old material, cutting off dead roots and all leafless pseudo-bulbs. The size of pot that is necessary should be determined by the character, condition and habit of the individual plant, always restricting the size for delicate subjects and treating vigorous specimens more liberally. If Fern rhizomes are used for the drainage material the receptacle may be made about one-third full, pressing the rhizomes in moderately firm, and if crocks are used a similar quantity will be suitable. The plant should be held in such a position that the base of the new growths is on a level with the rim of the pot, then fill in around with the mixture to within about an inch of the rim, pressing it firmly but not hard, and trying in the process to bring the loose roots as near to the sides and surface as possible without injuring the points. The remaining space to nearly the rim should be filled in with the chopped sphagnum-moss, used in a moderately dry condition so that it cannot be made hard. If good peat is plentiful I should prefer to finish off the surface with peat and sphagnum-moss in the old-fashioned way.

Subsequent Treatment.—Assuming that the plants are in a well-regulated house; their treatment during the present month and October will be very simple. In an amateur's collection the potting of the plants will extend over a considerable period, and therefore general and systematic treatment cannot be afforded the whole. Those that are only resurfaced will need more liberal

applications of water than those which are re-potted, but in neither case should much be given until new roots have entered the fresh materials. If the weather be favourable to the use of the sprayer, sufficient moisture may be afforded by this means. The surface-moss may appear dry, but immediately beneath it will almost sure to remain moist for a long time after being placed there. Free ventilation, especially at night, should be employed until the end of September, whenever the temperature out-of-doors is favourable. Shade the plants from direct sunshine, but do not allow the blinds to remain down longer than is essential.

THE HARDY FRUIT GARDEN.

By W. H. CLARKE, Gardener to Sir WILLIAM PLOWDEN, Aston Rowant House, Oxon.

Plum trees.—Aphides have been very numerous this season and trees that were cleansed previous to ripening their fruits have probably become infested again during the time when syringing was necessarily suspended. Therefore as soon as the fruit has been gathered from a tree, let the points of badly attacked shoots be removed, and then cleanse the tree with Quassia-extract if it is necessary. Varieties that will ripen later may be treated similarly. Supply such late varieties with sufficient nutriment to enable them to perfect first-class fruits. In the gathering of Plums let the fruits be handled very carefully so as not to destroy the "bloom," which is very attractive. Choice dessert Plums should not be gathered until they are quite ripe.

Peaches and Nectarines.—Examine the trees daily and gather all ripening fruits. A "dead ripe" Peach is worthless, but some varieties of Nectarines, as for instance Humboldt, are improved by over-ripeness and slight shrivelling. Immediately a tree has been cleared of its fruits cut out all the wood that will not be required for fruiting next season. The remaining shoots may then be lightly tied or nailed in, and the trees cleansed. Expose all late fruits to the sun and air by the removal of foliage, and if necessary a shoot. Trim in lateral growths, excepting where a strong shoot was stopped some time ago; the lateral growths from this may be advantageously tied in and are preferable to coarse and sappy shoots.

Planting of Fruit Trees.—Where it is proposed to extend the planting of fruit trees, a careful note should be made of the best varieties to plant in the particular district. This question needs close attention, as some varieties thrive and produce good crops of fruit in one locality, but entirely die out in another. [For varieties of Apples it will be useful to refer to the result of the Apple census published in the *Gardeners' Chronicle*, October 29 and November 5, 1904. ED.]

THE KITCHEN GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Wantage.

Tomatos.—Plants that are now ripening their fruits upon outside walls will be benefited if some spare lights be placed over them and made secure to the wall, so that wind will not displace them. As the temperature at night may now be expected to become gradually colder, the provision of a glass protection will cause the fruits to mature more quickly than they would otherwise do. Plants intended for fruiting in winter, but which have not yet been put into the final pots, should now receive attention. Use for this purpose soil that is of a light nature and only moderately rich. So long as the weather continues to be mild these plants will make most satisfactory progress if cultivated out-of-doors. Turn the pots on to their sides during heavy rains until the plants have rooted well into the fresh soil. Pots measuring 7 or 8 inches in diameter will be sufficiently large for winter-fruiting plants.

Onions.—If the tops of large specimen bulbs are still green and in a growing condition, bend them over to cause the bulbs to mature, but do not break them. It may be necessary in the event of the bulbs splitting to twist or partly raise the bulb. If seeds of winter varieties have not been already sown, as advised in a former Calendar, let the work be done without delay.

Lettuce.—In order to have plants that will stand through the winter, several sowings should be made during September on porous soil. If the plants are not too large they may pass through a very severe winter upon a deep, rich, sandy loam, when on cold clay or soil which is not sufficiently drained they would be likely to perish. Ground which has been trenched recently, provided the surface is well prepared by forking or digging, so that heavy rains may pass freely away, would be suitable. Allow plenty of space between all Lettuce plants, as this is more important now even than it was earlier in the season. Suitable varieties are Brown or Bath Cos, Hick's Hardy White, and Cabbage Lettuce Stanstead Park, an old and valuable variety for this purpose, which last spring I saw in a condition not easily surpassed for early spring use.

Vegetable Marrow plants will continue in a fruitful condition until cut down by frost. Do not allow the fruits to get very large before being cut from the plant, or fewer fruits will afterwards be produced, and the flavour of the large fruits will be poor.

French Beans are generally in request, and although they are plentiful at present in the open garden, in order to maintain a supply it is necessary to sow seeds in pots at the present time, using light, rich soil. Let the pots stand in the open-air until the appearance of frost.

THE FLOWER GARDEN.

By W. A. MILLER, Gardener to Lord HENRY C. BENTINCK, M.P., Underley Hall, Westmoreland.

Propagation of Roses by Cuttings.—This work should be commenced by the middle of the present month. The strongest and hardiest of H.P.'s and varieties of the Rambler type, &c., succeed very well by this method. Insert the cuttings in light soil on a well-drained border facing to the west or east. Obtain the cuttings from plants that require a little thinning. Make the cuttings 9 to 12 inches long, and let each have a "heel" of last season's wood attached to it. Take out a trench, and insert the cuttings two-thirds of their length in the ground at 6 inches apart. Sprinkle sand round the base, add a little soil, and then make the ground firm by treading. Afterwards dig 15 inches more soil, stretch the line, and insert another row of cuttings. Cuttings of free-growing H.T. varieties should be inserted round the sides of 6-inch pots, using a sandy compost. Place them in a frame over a mild hot-bed. When rooted they can be wintered in a cool frame. If potted-on next spring they will make good plants to put out in early summer.

Propagation of Shrubs.—The propagation of various shrubs may now be commenced. Choose a border that is protected from searching winds, and having loosened the soil, put about 6 inches of sandy compost on the surface, and cover with a frame. Obtain cuttings 4 to 6 inches long from the half-ripened tips of branches. Make a clean cut at a joint, and remove an inch or two of the bottom foliage; insert nearly half the cutting and make the soil firm about it; water thoroughly and shade from hot sunshine. A considerable measure of success may be secured from the undermentioned shrubs:—Cephalotaxus, Cupressus, Cryptomeria elegans, Cerasus, Garrya elliptica, Juniperus, Ligustrums, Hederas, Ilex, Retinosporas, Thuyas, Thuiopsis, Taxus, Osmanthus ilicifolius, &c. The following can also be inserted in pots and placed on a slight bottom, heat:—Buddleia variabilis Veitchianus, Ceanothus of sorts, Choisya ternata, Euonymus-Eurya, Schizophragma hydrangeoides, and others.

THE APIARY.

By CHLORIS.

How to commence Bee-keeping in Autumn.—Many of those who keep bees in straw skeps will be preparing to take the honey, first destroying the bees over sulphur fumes. If anyone wishes to obtain bees cheaply he may do so now. Find out someone who is desiring to take his honey, and then offer to drive the bees; he will generally be glad for you to do so.

The Accessories necessary for the Task.—Purchase a good smoker, by that I mean one with a good fuel chamber; this will cost about four to six shillings. Buy a piece of coarse black net about 1 yard long and 18 to 24 inches wide; fasten the ends, hem the top, and put in a piece of elastic long enough to fit the crown of a hat tightly. Draw this down to the rim of the hat and tuck the free side into the coat. This enables you to do the work with confidence, for then you cannot be stung about the face. Some purchase a pair of rubber gloves and a pair of gauntlets, but these only make one clumsy in handling bees, and often the insects become so infuriated that the manipulator is driven out of the apiary. A skep will be necessary to receive the bees, an iron skewer to act as a hinge, and a pair of driving irons, which a blacksmith would make for a few pence.

Driving the Bees.—Choose a fine warm evening; fill the smoker with some lighted brown-paper, corduroy, rotten wood, or rags, anything that will smoulder well and create a good quantity of smoke. Give the bees to be operated on a good puff through the entrance; this drives them to the honey, where they will gorge themselves as Nature dictates, in order to have sufficient material to convert into wax should they be removed to a home without comb. Whilst the bees are so engaged place an empty bucket in an open space

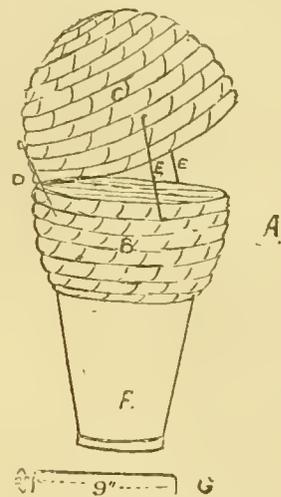

FIG. 67.—THE DRIVING OF BEES. (See explanations in text.)

some distance from the stand ready to receive the skep of bees when the stock have sufficiently gorged themselves, which will take two or three minutes. Give them another puff through the entrance to the skep, overturn the colony, and at once blow smoke over the combs to drive down the bees, which is the key to successful driving. Take the upturned hive and place it in the bucket; over the colony put the empty skep, and make it secure on one side with the iron skewer, raise the opposite side, and keep the top hive raised by means of the driving-irons. The illustration at fig. 67 will explain the operation:—A is the position for the operator with his back to the strong light; B, the skep containing the bees to be driven and the combs running from the operator; C, the empty skep to receive them; D, the iron skewer acting as a hinge; E E, the driving irons in position; F, the empty bucket, acting as a stand for the stock; and G is a driving iron with the dimensions marked.

How to Drive.—Tap the sides of B gently, and in a few minutes the bees will commence to ascend to the upper skep C. In about twenty to thirty minutes all the bees will have left B. Take off the irons and release the skewer D, overturn C and drop the bees into some receptacle, such as a bag of loose texture which will admit air. Drive others in the same manner and mix the lot. When home is reached, turn the bees out by shaking them on the frames containing full sheets of foundation and drive down with smoke. This done, cover up warmly with quilts and feed the bees with syrup.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.

APPOINTMENTS for SEPTEMBER.

SATURDAY, SEPT. 2	{ Société Française d'Horticulture de Londres meet.
WEDNESDAY, SEPT. 6	{ York Dahlia Show. Glasgow and West of Scotland Horticultural Society's Show (2 days).
THURSDAY, SEPT. 7	{ National Dahlia Society's Show at Crystal Palace (2 days) Faisley Horticultural Society's Exhibition (2 days).
TUESDAY, SEPT. 12	{ Royal Horticultural Society's Committees meet.
WEDNESDAY, SEPT. 13	{ Royal Caledonian Horticultural Society's International Exhibition at Edinburgh (2 days).
TUESDAY, SEPT. 19	{ London Dahlia Union's Exhibition at Earl's Court (3 days).
TUESDAY, SEPT. 26	{ Royal Horticultural Society's Committees meet; National Rose Society's Autumn Show (2 days); and National Dahlia Society's Committee meet in Royal Horticultural Hall, Vincent Square, Westminster.
FRIDAY, SEPT. 29	—Michaelmas, Quarter Day.

SALES FOR THE WEEK.

MONDAY, SEPT. 4—Flowering Bulbs, and 130 cases of Lillium Harrisii, at Stevens' Rooms, King Street, Covent Garden.

WEDNESDAY, SEPT. 6—Flowering Bulbs, at Stevens' Rooms.

For particulars of Messrs. PROTHEROE & MORRIS' Trade Sales, see pp. ii. and iii. of our Advertisement columns.

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —59'4".

ACTUAL TEMPERATURES:—

LONDON.—Wednesday, Aug. 30 (6 P.M.): Max. 60°; Min. 53°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—Thursday, Aug. 31 (10 A.M.): Bar., 30.2; Temp., 60°. Weather—Overcast, with occasional sunshine.

PROVINCES.—Wednesday, Aug. 30 (6 P.M.): Max. 60°, England, S.; Min. 54°, Scotland, E.

Fungous Pests.

In a communication to the National Horticultural Society of France on July 27 last, M. MANGIN, one of the Professors at the Museum at Paris, dealt with the subject of the moulds and mildews which attack plants under glass, and especially with the remedial measures to be adopted. Speaking generally these may be divided into two categories.

The first is that by which immunity from the attacks of certain diseases is secured, just as animals are inoculated to protect them from various contagious maladies. In this direction little or no progress has yet been made, and so far the experiments are but tentative.

The second means is the adoption of some method of sterilisation, which prevents the pest from developing upon the plants. Sterilisation can be effected in two ways. First, by heat, which has long been practised, having been advocated by MGR. DU BELLAY in the sixteenth century. In America steam is employed on a large scale for this purpose. The vapour is made to circulate

through a network of copper pipes pierced with holes and laid a few inches below the ground. The steam is formed by a generator, and is at a temperature of 90° to 100° C. (200° to 212° F.) when it comes into contact with the earth. The results obtained from the use of steam are excellent, numbers of eel-worms, mites, wire-worms, fungi, &c., being thus destroyed. Unfortunately the process is costly, working out at 1 franc 70 cents (about 1s. 6d.) per square metre (a yard and a third), and only reduced to 75 cents (or 7d.) however economically

from diseases, and among the chief of these is the antiseptic cleansing of all tools and appliances, such as stages, bell-glasses, frames, &c. It is necessary to wash these articles in some antiseptic, as, for instance, a one-per-cent. solution of sulphate of copper.

Other remedial measures, such as vaporisation with sulphur, nicotin, and cyanogen gas, are not mentioned by M. MANGIN.

BULBOPHYLLUM [BOLBOPHYLLUM] LOBBII COLOSSEUM.—Our Supplementary Illustration gives a representation of the fine specimen of this remarkable Orchid, which was exhibited by WALTER COBB, Esq., of Tunbridge Wells, at the Royal Horticultural Society's show held in the grounds of Chelsea Military Hospital, on July 11, and for which an Award of Merit and a Cultural Commendation were accorded. The original form was described by Dr. LINDLEY in the *Gardeners' Chronicle*, 1847, p. 423, and the variety colosseum was first shown from the Royal Botanic Gardens, Glasnevin, Dublin, on July 23, 1895. In colour the variety resembles the original type, but the flowers are much larger. They are of buff-yellow, faintly marked with purple, and have the odour of freshly-cut Cucumbers. The specimen illustrated plainly indicates that species reproachfully denominated "botanical," when grown into fine specimens, may be as effective as showier species. *B. Lobbia* is a native of Java, and requires to be grown in a warm-house. The hinged lip is peculiar, and becomes especially interesting when a fly having alighted on this part it is suddenly tilted over with its head against the column.

THE NATIONAL DAHLIA SOCIETY'S annual show will be held on Thursday and Friday next at the Crystal Palace. The Secretary, Mr. H. L. Brousson, informs us that there will be flowers from a number of new exhibitors, and that an exceedingly good display is anticipated.

LÉO ERRERA.—Belgian botany, which has so greatly suffered during the last five years in the loss of some of its most eminent members, has to mourn the sudden death of Dr. LÉO ERRERA, as we announced on p. 118. LÉO ERRERA was a brilliant Professor of Botany at the Free University of Brussels, who did honour to Belgian science. Possessed of a noble character and adequate means, he was not only a botanist, but a philosopher and a philanthropist. On the day of his death (which was August 2) he was seen in Brussels, active, spirited, and full of life. After the evening meal he complained of headache, and, following his mother's advice, he went for a walk in the park, where a short time afterwards his body was found in one of the main paths. The death occurred at his residence at Vivier d'Oye, at Uccle, near Brussels. LÉO ERRERA early acquired a prominent reputation in the scientific world by works not only in the botanical domain, but also in other branches of physiology and pure science. Since boyhood science had been his passion. To it he devoted his life with faith and zeal. He was an excellent professor, explaining his subject with clearness of method and incomparable elocution. He never lost an occasion to propagate any useful ideas, by lessons, lectures, in evening schools and in universities, &c. The list of his publications is considerable, and shows the variety and extent of his work. These publications are models of scientific diction. CRÉPIN was his first master in botany. ERRERA had for him a deep and affectionate admiration, and was working with zeal at his biography for the Belgian Academy of Science at the time of his death. At the recent Vienna International Congress of Botany LÉO ERRERA was designated as one of the Chairmen

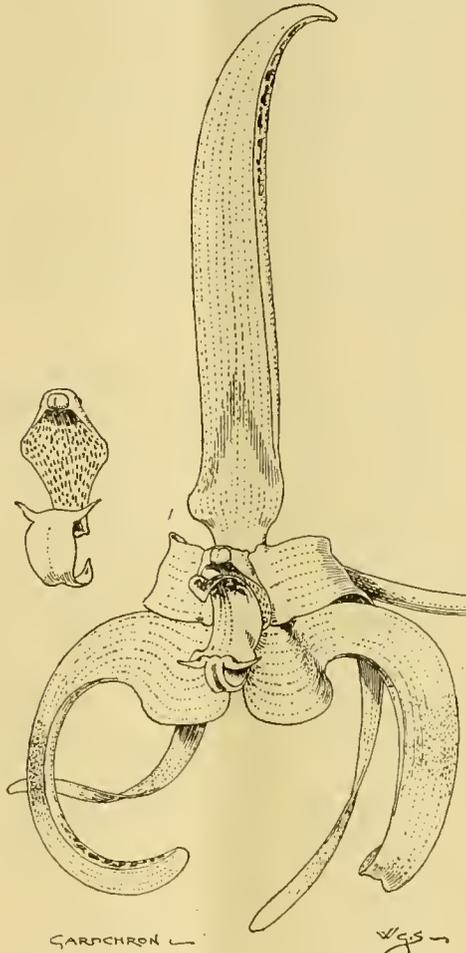

FIG. 68.—*BULBOPHYLLUM LOBBII COLOSSEUM*, Showing the hinged lip in two positions, as described in the text.

(See also Supplementary Illustration.)

managed. The great expense of sterilisation by steam renders it available only for very valuable crops, but as these are frequent in horticulture, there should be no hesitation about adopting the method in any case where the soil is so affected that it is impossible to grow the necessary plants upon it.

Sterilisation may also be effected by the use of antiseptics: salts of copper, naphthol, lysol, &c. These present certain difficulties. Salts of copper are very efficacious, but leave visible traces of their use. Further, long and patient observation is necessary to ascertain the exact dose necessary to kill the parasite without injuring the host-plant.

Naphthol does not stain the plants nor change their colours; it can also be used on food-plants without the risk of injury to men and animals who may eat the portions treated.

But there are always indispensable precautions to be taken when protecting plants

A FINE PLANT OF *BOLBOPHYLLUM LOBBII* COLOSSEUM, EXHIBITED BY W. COBB, ESQ., AT THE CHELSEA SHOW OF THE ROYAL HORTICULTURAL SOCIETY.

of the next Congress to be held in Brussels in 1910. He was a remarkable linguist, and at Vienna surprised the assembled botanists by discourses delivered with equal facility in several languages. LÉO ERRERA was a member of the Belgian Royal Academy of Sciences and Director of the Institute of Botany. He was 46 years of age. *L. G.*

THE SHREWSBURY SHOW.—In our report of the Shropshire Horticultural Society's show, we stated in our last issue that the exhibition was bigger and better than any previous one, and we now learn that the financial result constituted a record. The receipts on the first day of the show amounted to £813 7s. 4d., as compared with £405 5s. 9d. last year, and on the second day to £2,229 18s. 3d., as against £2,025 last year, making a total for the two days of £3,043 5s. 7d. The largest sum taken at any previous show was £2,923 1s. 3d. in the year 1902, therefore the receipts this year are £120 4s. 4d. to the good. It is interesting to record that in order to convey the vast numbers of people to the town, seventy special trains ran to Shrewsbury in the two days, and fortunately there was no accident. There were 355 bunches of Grapes shown, 72 of which were staged in the Champion Grape class. On p. 178 will be found an illustration of Lord HARRINGTON'S 1st prize exhibit in the class for sixteen dishes of fruit, prepared from a photograph kindly sent us by Mr. WALTER W. NAUNTON, one of the honorary secretaries. Mr. W. A. WATTS, St. Asaph, N. Wales, writes us to the effect that although he disposes of his surplus Carnation layers, he does not deal generally in nursery plants, and his exhibit of Carnations was a honorary one, for which he was awarded a Silver Medal. The firm described as Messrs. B. DOBBS & Co., Wolverhampton, in our report of the Medals awarded, should have been TOM B. DOBBS & Co.

THE LATE RICHARD DEAN.—The funeral of the late Mr. DEAN took place on Saturday afternoon last in Ealing Cemetery, when a large number of horticulturists and others paid their last tribute of respect to his memory. It is somewhat difficult to estimate the number that was in the cemetery, but about fifty well-known horticulturists, including those principally connected with the management of the National Chrysanthemum Society, were present, besides very many local people. Letters of sympathy also were received from upwards of forty who were unable to be present. No fewer than twenty-eight floral wreaths, crosses, anchors, or baskets were sent, including one of great size composed of Chrysanthemums, and sent by the National Chrysanthemum Society. Some of the donors were as follows:—The members of the National Chrysanthemum Society, the London Dahlia Union, the West Middlesex Building Society, the Ealing Horticultural Society; H. CANNELL, Swanley; HARRY and ARTHUR TURNER, Slough; WILLIAM MARSHALL, Chairman of the Floral Committee of the Royal Horticultural Society; SUTTON & SONS, Reading; JAMES VEITCH & SONS, Ltd., Chelsea; the Committee and Secretary of the Corn Exchange Chrysanthemum Society; Mr. A. B. WADDS, The Gardens, Paddockhurst, Crawley; Mr. and Mrs. HOWE, Streatham; and E. F. SUCH, Maidenhead. Mr. ALEXANDER DEAN, brother of the deceased, brought small posies of flowers to be thrown on to the coffin. The grave was lined with evergreens supplied by Mr. H. J. HOWELLS, Superintendent of the Ealing Cemetery, and flowers supplied by several horticultural friends. Mr. BEVAN supplied some white Chrysanthemums, which were employed next day to decorate the grave, a fitting tribute from the National Chrysanthemum Society's Committee. Mr. A. DEAN writes:—"Permit me the use of your columns to tender on behalf of my brother's

widow, his children, and myself, our sincere thanks to all those warm-hearted friends who sent letters of sympathy and flowers, or who attended at the graveside and saw him whom they had so well known and esteemed in life laid in his last resting-place. They came from far and near, many perhaps meeting on that spot after long separations, but all came for one object, to pay their respect for the last time to one who had known them all, but whose face they will never look upon again. My brother was not only an horticulturist, he was active in many other directions. To few men has it been given to live busier lives. He has left a void that cannot readily be filled."

NATIONAL CHRYSANTHEMUM SOCIETY.—On Tuesday evening last the Executive Committee met at Carr's Restaurant, Strand, Mr. THOMAS BEVAN presiding. The Chairman, pointing out the sad circumstances under which they assembled, alluded in feeling terms to the late Mr. RICHARD DEAN'S illness, and moved a vote of condolence with the family, which Mr. WITTY seconded. It was then stated that the officers had met together to consider what was best to be done at the present juncture, and they recommended that Mr. GERALD DEAN be appointed in his late father's place as Secretary *pro tem*. To this the Committee assented unanimously. It was also resolved that a Sub-Committee, consisting of the Officers and three members of the Committee, be appointed to consider and report as to the appointment of a new Secretary, his salary and duties. A Sub-Committee, consisting of the Officers and several members of the Committee, was elected to carry out the superintendence of the three shows to be held at the Crystal Palace during the forthcoming season.

IMPATIENS HOLSTII.—This showy species, of which an illustration was published on p. 14, has been exhibited several times as pot plants, and much admired. At the Royal Horticultural Society's meeting on Tuesday last Sir TREVOR LAWRENCE (gr., Mr. BAIN) exhibited a very large plant, as it had been lifted from the open ground and placed in a pot. Judging from this specimen, the species will make a first-rate bedding plant, for it was covered with its bright scarlet flowers, and appeared to be unaffected by the process of lifting.

PRESENTATION TO MR. HENRY ECKFORD.—Mr. ECKFORD being a native of Edinburgh, it was generally thought that no more fitting occasion than the period of the great International Show could be chosen for presenting him with some silver and an illuminated address which have been subscribed to by upwards of 200 admirers. On behalf of the Testimonial Committee Mr. P. MURRAY THOMSON, S.S.C., Secretary of the Royal Caledonian Horticultural Society, has very kindly made arrangements for the presentation to be made in The Hall, 5, St. Andrews Square, Edinburgh, on Thursday, September 14, at 3 P.M. Mr. PERCY WATERER, President of the National Sweet Pea Society, will take the chair. It is hoped that all the friends of Mr. ECKFORD who possibly can will be present. The subscription list, writes Mr. HORACE J. WRIGHT, Dault Road, Wandsworth, London, must be closed very shortly. The amount received up to Saturday, August 26, was £54 8s. 9d.

GRENADA (W. I.) FERNS.—Mrs. BROADWAY, the wife of the ex-curator of the Botanic Gardens, supplies named specimens of the Ferns of the island for albums or herbaria. Application should be made to Mrs. BROADWAY, The Bower, St. George's, Grenada, W.I.

IRISH GARDENERS AND EVESHAM MARKET GARDENS.—The Board of Agriculture for Ireland, being anxious that no opportunity should be

lost of improving the productiveness of the land of that island, are training instructors who will be placed in different districts. So that the knowledge of the instructors shall be as wide as possible, annual trips are taken to various parts of the kingdom, and this year the Vale of Evesham has been visited. The party was under the control of Mr. F. W. MOORE, Curator of the Royal Botanic Gardens, Glasnevin, Dublin, and consisted of eight instructors and eight pupils. They have been cordially received by the Evesham gardeners, who took considerable trouble to explain their methods. The Evesham men were impressed with the evident anxiety on the part of the visitors to learn all they could and their appreciation of what was done for them. The days were spent in wandering through the gardens and fruit plantations, and the impressions of the visitors are very interesting. In the first place they have observed the amount of individual effort which is made in experimenting. In Ireland, except, perhaps, in County Armagh, all this work would be done for them by the Department. Another point is the close manner in which every inch of land is utilised; nothing is taken up with big fences, and the extraordinary way in which catch crops are utilised so that the land shall never be idle very much impressed them. One or two doubted the wisdom of planting Beet between rows of young Strawberries, but it was pointed out that this not only did not harm the Strawberries but ensured that the land was kept clean. The readiness of one gardener to supply another with a particular variety of seed which had been found to answer in the district very favourably impressed the visitors. They considered the land to be in a very clean condition; but it was pointed out to them that in this respect the district is not now at its best; weeds have been growing very fast recently, and all the labour is required to harvest the Plums, although these are thin enough in some places. They were delighted, too, with the appearance of the fruit trees; the bark and foliage alike is so clean and healthy-looking that it was evident to them that spraying is extensively and regularly practised. Perhaps that is so in the plantations where the visitors have been, but there are others where much has yet to be learnt on this question. They also approved of the system of pruning adopted in the Vale, but were of opinion that their own plan of cutting more into the centre of the Apple trees is beneficial. The absolute absence of farmyard manure caused them great surprise. Everywhere in Ireland a heap of this manure would be seen, but it was explained that not only is it impossible to obtain the manure at Evesham in sufficient quantities, but experience has taught the growers that artificial manures are so suitable for particular crops and soils that the absence of farmyard manure is not felt at all. The visitors were astounded at the extent to which Tomatoes, Cucumbers and Vegetable Marrows are grown in the open fields round Evesham. This would be quite impossible, they say, in Ireland, as the atmosphere is too humid and there is not sufficient summer sun. The local markets have been visited, and the Irishmen were struck with the celerity with which the large number of lots were disposed of, and with the general air of activity and bustle which prevailed. The prices obtained rather disappointed them after those ruling at Dublin, but it was explained that probably the produce had to pass through two or three more hands before it reached the retailer, and everybody wanted his share of the profit. In addition to local gardens a large nursery at Worcester has been inspected. Maresfield has been visited, and also the large fruit plantations at Toddington. The visitors remained at Evesham for a week, and spent an enjoyable and, it is hoped, a beneficial visit.

THE GROWTH OF PLANTS WITHOUT CARBONIC DIOXIDE.—M. LÉFÈVRE has recently contributed a paper to the *Académie des Sciences* upon the development of plants exposed to light, but entirely deprived of carbonic dioxide in an artificial soil containing amides [crystallizable substances allied to ammonia but containing less water]. He begins by observing that the carbonic acid of the atmosphere is not the only source whence green plants may derive their carbon. By a series of experiments, M. LÉFÈVRE proved that in soil containing a suitable quantity of amides green plants could be developed though deprived entirely of carbonic acid gas. The plants increased to five or even ten times their height, multiplied their leaves, and the tissues were formed normally. When both carbonic acid and amides were absent the growth was arrested. Therefore growth under a glass in soil containing amides is effected by a process of nutrition.

PUBLICATIONS RECEIVED.—From the Lancashire Education Committee, Agricultural Department: *Scheme of Agricultural Education*, to be carried out in various farms and schools throughout the county during session 1905-6.—*The Journal of the Board of Agriculture*, August: Principal contents—Effect of Blue-stone and Formalin on Germination, Diseased "Evergood" Potatoes, Blackleg in Potatoes, Prevention of the Cabbage Flea, Bacterial Disease of Tomatoes, Preventing the Decay of Ripe Fruit, Larch Canker (*Dasycephala calycina*).—*Report on Rubber in the Gold Coast*, by W. H. Johnson, Director of Agriculture. Many efforts are made to induce native chiefs to plant rubber trees, but much instruction is still necessary if this industry is to be fully developed. *Hevea brasiliensis*, the Para rubber tree, appears to yield the best results when given a fair chance. Careless tapping and the tapping of immature trees have caused the waste of much good material.—*Report of the Nova Scotia School of Horticulture*. This bulletin, to December 31, 1904, is the last that will be issued, as since May in that year the School was closed as a separate institution and merged into the Nova Scotia Agricultural College, established at Truro. Excellent work in spraying and in connection with fruit-culture was done, and Professor Sears is to be congratulated on his success.—Ontario Agricultural College. Bulletin 144: *Apple Culture*, by H. L. Hutt. A useful practical pamphlet.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his Correspondents.)

POLLARDING OF BURNHAM BEECHES.—The article on Burnham Beeches in the *Gardeners' Chronicle* for August 19 repeats the tradition that the old trees were beheaded by Cromwell's soldiers. The tradition goes still further, and asserts that they were dressed up in military costume to frighten the Royalists; while another version has it that they served as gun-platforms from which Windsor Castle was bombarded. In fact, so many unlikely theories have been advanced regarding the pollarding of the Beeches that it is worth while considering one which contains some elements of probability. Some years ago I made a careful examination of a few limbs blown off in a gale, and from the rings at the butt-end found that about 200 years had elapsed since the last general pollarding took place. This period would fit in very well with the Cromwellian theory, and they are just as likely to have been pollarded by Cromwell's soldiers as by anyone else in want of firewood. But to those at all acquainted with tree growth, it is quite evident that the trees owe their appearance not to one, but to successive pollardings, extending over at least several centuries. The enormous girth of the boles, together with the gnarled and fantastic appearance of the base of the crowns, make this perfectly clear, and no isolated case of mutilation could produce the same effect. Some other agency than that of Cromwell's army must therefore have been at work to satisfactorily account for such abnormal specimens of forest growth as are represented in this woodland, and the following seems to be the most reasonable explanation of it. It is a well-known fact that the tree growth on all unenclosed land was carefully preserved in olden times, and that rights of cutting fuel were either restricted to certain species or to certain methods of cutting. When enclosures were the exception rather than the

rule, the regeneration of forest growth was a difficult matter on land grazed by live-stock, while the growth of coppice shoots from the surface of the ground could only take place to a limited extent. This gave rise to the custom of pollarding the trees at a height above ground which would place the growth of new shoots above the reach of grazing animals, and thus ensure the perpetuation of the fuel supply. That the trees in Burnham Beeches were pollarded for any other purpose than this is extremely unlikely. The only remarkable feature about them is the fact that they are practically unique as regards their size and age in Europe, so far as Beech trees are concerned. We have abundance of Oaks, a large number of Ash, Elm, Willow, Yew, and, in the case of Epping Forest, Hornbeam, but it is only occasionally that one meets with a pollarded Beech. It is quite possible that Burnham Beeches was at one time within the boundary of Windsor Forest, and it is practically certain that the ground was never enclosed, the poverty of the surface soil prohibiting any form of cultivation. Why the practice of lopping ceased about 200 years back no one seems to know, but that its cessation occurred at a definite period, and was not partial or gradual, is evident from the appearance of the trees. There is, I believe, a rumour that the wood supplied fuel or charcoal for Windsor Castle, and if there is anything in it the more general use of "sea coal" or pit coal about that time might account for the lopping being discontinued. Whatever the motives may have been, however, the pollarding has produced one of the most interesting pieces of woodland in the country, and the only cause for regret is the fact that another century or so will see the disappearance of these old trees from wind and decay. A great deal has been done of late years to preserve them by bracing together the branches, but the most certain way of preserving them would be a return to the old custom of pollarding, and by thus relieving the hollow boles of the overhead weight enable them to stand for an almost indefinite period. How such a step would be received by the public may well be imagined, but that it could be done to a certain extent without interfering with the general appearance of the wood is a fact. *A. C. Forbes.*

ANNUALS.—The attention of exhibitors and judges of annuals ought to be directed to the definition of annuals as given by the Royal Horticultural Society in their Rules for Judging. Rule 160 is as follows:—"Annuals are plants which, naturally, begin and end their growth, and ripen seed and die within twelve months." At the recent flower show in Shrewsbury there were nine exhibitors in the class for twelve annuals, several of them, including the 1st and 2nd prize winners, had among their exhibits flowers that cannot be strictly called annuals, such as *Verbena hybrida*, *Scabiosa*, *Chrysanthemum inodorum*, and *Petunia*. Some gardeners to whom I have spoken on the subject say that these flowers and others can be grown as annuals—i.e., they can be grown from seed and flowered the same year; but so also can *Geraniums* and many perennials. I hope this matter may be taken up, and something definitely decided upon as a guide both to exhibitors and judges. *Amateur.*

GERMINATION OF SEEDS.—At a recent meeting of the Scientific Committee of the Royal Horticultural Society the Rev. W. Wilks mentioned a curious case of long-suspended vitality in Poppy-seeds. A clearance in the vicinity of his garden at Shirley resulted in the sudden and abundant appearance of single-flowered *Papaver somnifera*, obviously arising from seeds lying in soil which had lain undisturbed for at least twenty-six years—i.e., since he had been at Shirley, and how much longer it was impossible to say. As no such Poppies were known in the vicinity, the inference is unavoidable that they originated from seed at least twenty-six years old. Mr. Druery cited the case, recorded some years ago by him, of an abundant crop of double Poppies of this species which had appeared in a garden at Warton, near Carnforth, on the heaps of soil excavated to form cellars beneath a house there which was at least

a century old, indicating an even longer vitality. These, strange to say, were all of a peculiar leaden-grey tint, but were very double, while Mr. Wilks's examples are of the same colour but single. In the Warton case the Poppies were entirely confined to the heaps of soil thrown out from the excavations, and were not known in the vicinity at all. This case was equally well evidenced as that of Mr. Wilks's, for Mr. Druery, visiting Warton, saw the plants in full bloom, and ascertained the facts from the mason employed on the building, who was an ardent Fernist, an observant man, and could be entirely relied upon, apart from the fact of the confinement of the plants to the excavated soil. The difficulty of determining the longevity of seeds by actual systematic experiment is extremely great, owing to the very long periods required, and the necessity of treating them under similar conditions of deep burial and isolation from disturbing or stimulating influences. It would certainly appear that given such protection some seeds maintain their germinating powers for quite indefinite periods, and it is a well-known fact that deep excavations such as are made for railway cuttings frequently result in the appearance of plants which have become total strangers in the locality, and cannot therefore be imputed to freshly scattered seeds. In such cases, and in view of similar facts to the above, the idea that vitality can only be maintained at the expense of some consumption of the seed contents, would appear to be fallacious, especially as in the Poppy cases cited the seeds are extremely small. This, indeed, is probably a factor in their preservation, as larger ones would certainly be more apt to fall a prey to insects in the soil or fungoid attacks. It would at any rate be interesting if all such cases could be recorded, since, for the reasons above given, direct experiment is practically impossible owing to the time involved. *Chas. T. Druery, V.M.H., F.L.S.*

—With regard to "T. R. P.'s" experience with the non-appearance of seedlings, the failure is certainly not always due to bad or old seeds sent out by seed-merchants. It has always been a puzzle to me why so few seeds germinate from the myriads which are annually and naturally shed in a garden. Perhaps Foxgloves and Poppies shed more seed than most herbs—a large plant of the former bore, by calculation, a million and a half of seeds—but the number of seedlings may be twenty or so round about the plants. No seedlings ever appeared in some *Rhododendron*-beds known to the writer for twenty years, though the pods burst every year. Several seedlings may be found under a *Laburnum*-tree, but nothing like the number of seeds shed. So is it with many other trees and herbs. In the present year I sowed a number of annuals in March from seed purchased from Messrs. Ware. They all came up and blossomed well. The rest, from the same packets, were sown in April. A prolonged drought followed soon after. In many cases none came up at all; of others, a few only. I would suggest that perhaps the seeds germinated underground, but were killed by the drought, for I did not think of searching for them. Perhaps this experience may explain the non-germination of "T. R. P.'s" seeds of *Eucalyptus citriodora*. With regard to seeds lying dormant, when I went to Holland Park in 1898, the neglected garden (attached to my house) abounded in Docks; for six years seedlings came up, but were of course destroyed, so none seeded during that time. But why so many self-sown seeds should every year fail to appear is a mystery. *George Henlow.*

LAPAGERIAS.—In the *Gardeners' Chronicle*, on p. 166, Mr. Smith, writing from Sussex, says:—"Lapageria alba and L. rubra superba are also hardy here." As far north as Lincolnshire twenty-five years ago, I grew Lapagerias very successfully against a wall with a north aspect at the back of a vineyard without any other protection whatever: the plants flowered well until the end of the year. Mr. Nicholson also wrote (in 1885) in his *Dictionary of Gardening*, "Lapagerias succeed on walls and trellises outside in the warmest parts of the country, and are not injured by a little frost." *J. Ward, Ascol.*

GLADIOLUS TRISTIS CONCOLOR.

THIS *Gladiolus* is very rarely met with in gardens, but is one of the most valuable species, since it is the earliest of all to flower, being at its best toward the end of April. It is perfectly hardy in the south-west of England, even when planted only 3 inches below the surface and unprotected during the winter. The plants increase very rapidly both by offsets from the corms and by seed.

fragrant after twilight, and if a group of thirty or more flower-scapes is situated near an open window it will flood the room with delicate perfume. The leaves are rush-like, and show a section like a cross in form when cut horizontally. They are often nearly 3 feet in length. Strong flower-scapes will carry as many as four or five blossoms, all of which are expanded simultaneously, and which measure $3\frac{1}{2}$ inches across. *S. W. Fitzherbert, Devonshire.*

FIG. 69.—GLADIOLUS TRISTIS VAR. CONCOLOR: COLOUR OF FLOWERS SULPHUR-YELLOW.

If the flower-spikes are allowed to remain on the plants after the blossoms have withered, seed will be freely produced, and the next year numbers of self-sown seedlings will appear around the parent clumps. In horticultural dictionaries its height is given as 1 foot, but in the south-west the plants grow to a height of from 3 to 4 feet, and even taller.

G. tristis is very variable in colour, the form almost invariably sent out by nurserymen when this species is ordered having the three upper petals marked with a purplish-black band down the centre; this is inferior in beauty to the subject of this note, whose flowers are of a uniform pale sulphur-yellow. This is known as *Gladiolus tristis concolor* or *G. t. sulphureus*. The flower has the additional merit of being deliciously

HALF-HARDY SHRUBS.

On reading Mr. Fitzherbert's very interesting and suggestive description of Rosehill, Falmouth, on p. 103, one can scarcely help lamenting the comparative rarity in present-day collections of many of the fine plants found in Mr. Fox's garden. Without disparaging the favourites of to-day, I contend that the reintroduction of some of those of former times would afford owners of gardens much pleasure, even though in some instances the blooms might not be useful for cutting purposes. Not all of them require large glasshouses for their cultivation, and when the plants have reached a desirable size it is easy to maintain them at that size by root-pruning and repotting in pots or

tubs of similar dimensions to those they are occupying. Moreover, a few of each species can be kept in stock by occasional propagation by cuttings, layers, or seed.

Taking the plants in the order named in the note, there are *Acacias lophantha*, *longifolia*, *dealbata*, and *verticillata*, which flower under greenhouse cultivation early in the year; their management is of the easiest kind, repotting or surfacing soon after the flowering is over, some slight amount of pruning and cutting into not too severe a form being the only matters needing attention; and in early June standing them out-of-doors, preferably sinking the pots to the rims in a bed of fine gravel or coal ashes. Young plants not of flowering size may be grown on in cold frames, and receive one or two small shifts during the summer, the lights being drawn off in fine weather, but replaced on the frames during heavy rains. The proper kind of soil consists of hard peat one-third, leaf-mould and decayed wood refuse one-sixth each, and one-third medium loam, together with plenty of coarse, clean sand. The same kind of mixture answers for surfacing. Insects, with the exception of white scale, seldom trouble *Acacias*, and this pest is found only on the old wood, and can be readily destroyed by applications of petroleum emulsion or Gishurst's Soap. I would add to those named the beautiful *A. Drummondii*, with its cheerful-looking yellow catkins and neat foliage. *Boronia megastigma* is well known and highly appreciated for its fragrant brown flowers, abundantly produced from May till July; but there are others which if not furnished with fragrant flowers are in other respects very ornamental and uncommon in colour, viz., *B. serrulata*, *B. elatior*, and *B. heterophylla*. The whole of these require a compost largely consisting of hard peat, say, four-sixths, and two-sixths light fibrous loam, with much silver-sand mixed with these; and the pottings, as is the case with all these fine-rooted plants, requires to be done firmly. The plants should be kept under glass, or at the least be provided with protection from excessive rain during the summer and early autumn months. *Cantua dependens* may be treated similarly to the *Acacias*, and be frequently syringed so as to ward off infestation by red-spider, which, if present in great numbers, is sure to disfigure the leaves; *Coronilla glauca* and other species; also *Correa viminalis*, *C. cardinalis*, *C. magnifica*, *C. speciosa major*, and others, including *alba*, an easily propagated species, and useful as a stock on which to graft the others, are easily managed if grown in a mixture of equal parts of light loam and hard peat, with enough sharp sand to make it porous.

Habrothamnus (*Cestrum*) are showy plants, more especially *H. aurantiacus*, *H. elegans*, and *H. Newelli*, of easy culture and excellent as wall and pillar plants planted out, or for pot or tub culture, *Datura sanguinea*, *D. s. lutea*, and *D. arborea*, being plants of large growth, are better suited for big glasshouses than for smaller structures. The plants succeed in rich, heavy loam, and should be afforded considerable quantities of manure-water during the summer when grown, as they may be, for years in the same pot or tub. The plants form highly ornamental objects when placed in sheltered spots in the flower-garden in the summer-time. *Eugenia apiculata* and *E. Ugni* are tall, Myrtle-like shrubs, succeeding in pots filled with peat, loam, and leaf-mould in about equal quantities, and when they get as large as is desirable, leaf-mould may be dispensed with. The flowers resemble those of the Myrtle, and *E. Ugni* produces blackish-purple, edible berries. The foliage of *E. apiculata* is extensively employed by continental florists in bouquet-making. *Grevillea rosmarinifolia* is mostly known in this country as an ornamental foliage plant for planting in summer beds, but this and other species, as *Fosteri*, *Preissoi* and *robusta*, are excellent

conservatory plants with remarkably showy blossoms.

Pittosporums, although sufficiently frost-proof to stand out-of-doors in our southern and western maritime counties, are not to be despised for conservatory decoration in the less mild districts, their creamy-white flowers, and later, the expanding seed vessels holding scarlet-coloured fruits, being decidedly ornamental. A mixture of loam (two-thirds) and peat (one-third) is desirable. The flowers are mostly sweet-scented. *P. tenuifolium* has a nice, neat habit, and *P. Tobira* forms an excellent plant for covering a wall either indoors or out-of-doors. Besides the species of *Solanum* mentioned there are *S. hybridum* and *S. jasminoides*, both of which are worthy of indoors cultivation, being extraordinarily floriferous. Their cultivation presents no difficulties if a light loamy soil be chosen.

The *Hedychiums* are Ginger-like plants with spikes of deliciously fragrant flowers produced well above the foliage. The plants are of easy growth, and need during the winter, their resting period, about the same sort of treatment as that accorded to *Fuchsias*. A heavy loamy soil is best for them. I have not known *Rhodochiton volubile* to be grown the whole year round out-of-doors; usually one sees it as a rafter or pillar plant in the greenhouse; and it is highly ornamental in such positions, the black and purple-coloured flowers being then most readily observed. My purpose will have been served by these brief notes on plants once common in English gardens if the attention of some of the readers of the *Gardeners' Chronicle* are drawn to these rather neglected plants. *F. Moore.*

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and General Summary, ante, pp. 81-87.)

(Continued from p. 153.)

7. ENGLAND, N.W.

LANCASHIRE.—The failure of Pear and Plum trees to develop crops is due to the cold, dry easterly winds which prevailed for weeks in spring, bringing insect pests in their train. Nothing suffered in this garden from frost. A couple of miles distant from here is an orchard of healthy Apple and Pear trees, which the owner informs me are bearing scarcely any fruit. Bush fruits, as usual, are full crops, and the bushes are in good condition. The same remarks apply to Strawberries. *W. P. Roberts, Cuerden Hall Gardens, Preston.*

— The fruit crops generally in this district are very poor, owing chiefly to the severe drought which has caused most of the fruit to fall. Great damage was also caused by bad weather when the trees were in bloom. The soil in these gardens is a cold heavy loam resting on a clay subsoil. *E. F. Hazelton, Knowsley Gardens, Prescott.*

8, ENGLAND, S.W.

CORNWALL.—The bush fruit crops in this district are extra good and the fruit is of excellent quality. Crops of Peaches, Nectarines, Plums, Apples, and Pears, however, suffered considerably from the late frosts and from the storm of April 30 and May 1. *Alfred Read, Port Eliot, St. Germans.*

— An unfavourable spring has again ruined what might otherwise have been bountiful crops of Apples, Pears, and Peaches. Bush fruits, being more sheltered, have produced exceedingly good crops. Fruit-trees of all descriptions flowered well. Peaches set a heavy crop, but a fierce gale nearly killed the trees. We are situated at a very high elevation, being almost 400 feet above sea-level. Our soil is very "hungry" and stony, but is amenable to good culture. *A. C. Bartlett, Pencarrow Gardens, Washaway.*

— Our soil is a heavy, adhesive loam on a clay subsoil. Peach and Nectarine-trees are carrying the best crop for some years past, and are more free from blight and blister than they have been for twenty years. Apple and Pear-trees were much blighted by the cold nights in May, in consequence of which there will not be more than half crops of these fruits. Small fruits are abundant and of good quality. *Wm. Sangwin, Treilissick Gardens, Truro.*

— The Apple and Pear crops promised well when the trees were in bloom, but owing to the chilly nights in May very few fruits developed. Strawberries were a moderate crop. *Richard Gill, Tremough Gardens, Penryn.*

— The whole of the fruit crops in this district looked remarkably well, and there was every appearance of a first-class crop until the first week in May, when severe gales injured the leaves of Peaches, Apples, Nectarines, Pears, Plums, and Apricots, causing a great number of the fruits to drop. Our soil is a light loam. *W. H. Bennett, Menability, Par Station.*

DEVONSHIRE.—Apple, Pear, and Plum trees are carrying very slight crops of fruit, for although there was a good show of blossom it failed to develop. This was probably due to the autumn of 1904 being dull and damp, when the trees became covered in moss, and the fruit-buds failed to develop perfectly. Although some of the flowers appeared to set well much of the fruit has since dropped. Strawberries have been extra good. Gooseberries and Currants also carried good crops of extra fine fruit. *Geo. Baker, Membrand Gardens, Newton Ferrers, Plymouth.*

— The fruit prospects in this district were excellent early in the season, almost all trees showing an extra amount of blossom, but these hopes have not been realised. The May frosts ruined the Apple crop. Pears and Plums are also unsatisfactory. The Pear-midge has done much damage among the Pear trees. Plums are plentiful on some trees; others have few or none. Strawberries were produced in abundance, but many of these fruits rotted away owing to excessive rains. Small fruits are abundant, and good in every respect. Our soil is warm, light, though deep, and rests on the Old Red Sandstone. *James Mayne, Bicton Gardens, East Budleigh.*

— The Pear crop is very light, and there are only fruits upon wall-trees. Among Apples the varieties with most fruit are Cox's Orange Pippin, Mère de Menage, Tower of Glamis (most reliable), Lord Grosvenor, Warner's King, and James Greive. Among Plums the varieties Czar, Early Prolific, Victoria, Monarch, and Kirke's are carrying the best crops. Peaches suffered badly from blister. Our soil is a heavy loam, and forms a good soil for fruit-trees. *T. H. Slade, Pottimore Gardens, Exeter.*

GLOUCESTERSHIRE.—The frost affected our Strawberries just as they were in bloom and did extensive damage to the Pear crop. Currants and Gooseberries are a very heavy crop. *William Keen, Bowden Hall Gardens, Gloucester.*

— Our Apple-trees, on which American blight is very prevalent this year, did not develop much bloom. Pears flowered well, and this crop on the whole looks promising. Of stone-fruits we have a fair crop; the trees bloomed well. Peaches set an abundance of fruit, but many dropped owing, in my opinion, to the cold, dry weather in May. Bush and small fruits are good. Filberts are also plentiful. The soil is of a clayey nature. The total rainfall in May was only 17 inches, while the wind was from a northerly point for twenty days. *John Banting, Tortworth Gardens, Falfield.*

— Apple, Pear, and Plum-trees flowered well, but set very indifferently, the whole of the fruit having since dropped from quite half the trees.

Gooseberries and Currants, both Red and Black, are abundant and of good quality. Strawberries were a failure in this neighbourhood. In our garden a full crop of these fruits set, but quite half of them decayed before they were ripened. All vegetable crops are plentiful and good. *W. H. Berry, Highnam Court Gardens, Gloucester.*

(To be concluded.)

THE FERNERY.

FERN HUNTING IN SCOTLAND.

A THREE weeks' stay in Scotland, a fortnight in Aberfeldy, and a week in Glasgow, gave me opportunities for several spells of Fern-hunting, and although they were not crowned with so much success as usually falls to my share, the accompanying illustration (see fig. 70) of a very fine form of the common Bracken (*Pteris aquilina*) will show that I did not fail in my quest entirely. Unfortunately this was a most tantalising find, as will be seen. I took the train from Aberfeldy to Pitlochry, hoping to find good hunting-ground there, but to my disappointment, although the roadsides appeared promising, stone dykes, mostly retaining walls to earthen banks, for more than two miles up the Tummel I hardly found a Fern, and even on the slopes there were too few to constitute good ground. The further I went the more I was disgusted, especially as the day was hot. Hence, finding that I must either return at once or lose the chance of a train for several hours, I turned and walked rapidly back, relinquishing hunting altogether, and when I reached the Tummel bridge, seeing a path by the river, evidently a short cut, I took it. Immediately I did so I noted the remarkable find above referred to some few yards down the river-bank, and on descending I found it, to my delight, not only extremely crispate and congested, but beautifully tasselled at all terminals—a thoroughbred, and a new one. Now comes the tantalising part: the frond, about a yard high, stood absolutely alone, and all those in the vicinity, yards away, were normal. It sprang from hard, rocky, stony ground, and to attempt to dig it out would, I knew, especially in summer, be simply murder. Examining the frond, too, I found no trace of a spore, and consequently all I could do was to take the frond, carefully fold it, and place it inside my waistcoat as a trophy, knowing full well that the plant was too well established not to assert itself again despite this acquisition. I caught my train, and on reaching home unfolded the frond and placed it in a bath, where it speedily resumed its pristine beauty; and after three days I was fortunate enough to find an amateur photographer in Mr. Dawson, of Aberfeldy, who most successfully secured two photographs, one from the back and the other from the front, which form my only souvenir, the frond itself, though pressed and dried, shrinking so much as to lose its chief charm. This was my only "prize," but several other abnormal sports fell to my lot. These included a mediodeficient Lady Fern with central pinnules and pinnulets reduced to thorns, leaving on both frond and pinna an open, central space.

This represents my fifth find of this curious type in widely distant places. *Lastrea montana truncata* with square ends tipped with thorns I found as usual in two places, neither plant however was thorough. It is very curious that one frond of such a marked type throughout should occur in a plant otherwise perfectly normal. A novelty in *Blechnum* I found near Grandtully, each frond having short round lobes halfway up the frond, then a normal portion, and then a distinct caudate top formed again of short round lobes; this is quite thorough in three plants, the fertile fronds presenting same character in the first find, while the others were
